Apparatus used—one metre bridge of platinum-iridium wire with a supplementary coil at each end of 20,012mm.; suspended coil galvanometer, resistance 15 ohms (Muirhead and Co.'s); trough 45in. by 7¼in. by 5in., depth of water 2⅜in., quantity of water 6¼ gallons; battery used, one Hellesen's dry cell, Nr. 3; E.M.F. 1·4 volt.

The interest attaching to these tests lies especially in the fact that the standard coils have been exposed to the climate of Calcutta for 24 years. They were made, I understand, by Dr. A. Muirhead when in Dr. Matthiessen's laboratory, under the supervision of the latter.

In reducing the observations from 20·2 to the temperatures given it has been assumed that all the coils have the same temperature coefficient.

E. O. WALKER, C.I.E., M.I.E.E.,
(late Superintendent in the Government Telegraph Department in India).

APPENDIX VI.

On the Specific Resistance of Copper and of Silver.

BY REV. T. C. FITZPATRICK.

As lately several observers have published the results of measurements made on the specific resistance of copper, it may be worth while to collect these results together in tabular form.

The resistances of metals may be expressed in terms of equal weight or of equal volume—that is, as the resistance of a wire of the given material such that one metre of it weighs one gramme, or as the resistance between opposite faces of a cube of the material, each face of which is one square centimetre.

I have pointed out that Matthiessen* considered the first as the most satisfactory mode of expressing resistances, and for these results alone did he make all the actual experiments. The results for specific resistances were calculated from these, with the help of specific gravity values obtained in many cases from tables, and not determined directly for the wires used.

Only in the cases where considerable masses of the material are used can the specific gravity from this the cross-section of the wires be accurately determined. There is therefore an evident advantage in expressing results in terms of weight when the determination of the cross-section of the wires becomes unnecessary, and there is no reason why an accuracy of one in two or three thousand should not be attained.

Again, it is found that different samples of copper have different densities according to the method by which they have been prepared. In a table* which I published on a previous occasion the variation is from 8·86 to 8·95. Mr. Swan† gives a value as high as 8·9587.

From samples of copper of the same quality I have had wires drawn which differed in density. It was always found that the denser the copper the less is its resistance, and the difference affects much more the results expressed as specific resistances than when expressed as the resistance of a gramme per metre.

This is another reason for expressing the results in these terms at least as well as in specific resistances, and for actual practical purposes it is a question of weight rather than volume.

In the following tables the results are given for a temperature of 18deg. C. in C.G.S. units:

* B.A. Report, 1890, p. 129; *ibid.*, p. 125. † *Nature*, vol. l., p. 165.

Digitized by Google

TABLE A.—Hard-Drawn Copper Wires.

Resistance of wire such that one metre weighs one gramme	Specific resistance per cubic centimetre.	Observer.
$1,550 \times 10^5$	1,743	Matthiessen.[1]
—	1 720	Swan and Rhodin.[2]
1,550	1,726	Fitzpatrick.[3]
1,527	1,708	,, (copper supplied by Messrs. Bolton).

TABLE B.—Annealed Wires.

Resistance of wire such that one metre weighs one gramme.	Specific resistance per cubic centimetre.	Observer.
1,516	1 704	Matthiessen.
—	1,681	Fleming and Dewar.[4]
—	1,680	Swan and Rhodin.
$1,488 \times 10^5$	1,665	Fitzpatrick (copper supplied by Messrs. Bolton).
1,488	—	(Wire sent by Mr. Swan.)

[1] B A. Report, 1864 [2] *Nature*, vol. l., p. 165. [3] B.A. Report, 1890, p. 125. [4] *Phil. Mag.*, vol. xxxvi., p. 287.

From Table A, it will be seen that Messrs. Swan and Rhodin obtained a value rather lower than that which I got for copper which I had prepared myself, and which expressed as the resistance of a wire one metre long weighing one gramme is identical with the value that Matthiessen obtained; but the resistance of all these specimens is distinctly greater than that of the copper kindly sent me by Messrs. Bolton, which seems to bear out the statement which I have previously made that it is impossible to prepare wires on the small scale which are of the same quality—*i.e.*, probably due to density—as the best specimens specially prepared by large manufacturers.

In Table B are given the results of measurements with three specimens of copper prepared by Mr. Swan. One was given to Messrs. Dewar and Fleming, a second was examined by Mr. Swan himself, and a third specimen he kindly sent to me; the quality of the copper in the three cases may therefore be expected to be the same.

The results of Messrs. Dewar and Fleming and Messrs. Swan and Rhodin are expressed only as specific resistances, whilst the result of my measurements is only given for a wire one metre long weighing one gramme. The weight of the copper wire, as measured, was only three grammes, and that does not allow the accurate determination of the specific gravity of the sample; the value I obtain for it is identical with that for the sample of annealed copper wire sent me by Messrs. Bolton.

If I consider it to have the same specific gravity as that sample (8·94), I get as its specific resistance in C.G.S. units, 1,665, a value distinctly smaller than that obtained by Messrs. Swan and Rhodin, whose result is practically identical with that of Messrs. Dewar and Fleming.

Not only may wires drawn from the same specimen of copper have different densities and different resistances, but the variation of that resistance with change of temperature is also different.

In the following table are given the temperature coefficients of various specimens of copper :

$$R_t = R_0 (1 + a\,t).$$

R_0	a.	Observer.
—	·00387	Matthiessen.[1]
1,561	·00428	Dewar and Fleming.[2]
1,603*	·00408	Swan and Rhodin.[3]
1,563	·00417	—
1,592*	·00405	Fitzpatrick.
—	·00406	Kennedy and Fessenden.[4]
—	·00364	Benoit.[5]

* Hard-drawn wires.

[1] B.A. Report, 1864. [2] *Phil. Mag.*, vol. xxxvi., p. 287. [3] *Nature*, vol. l., p. 165. [4] *Electricity*, vol. v., p. 165. [5] *Comptes Rendus*, vol. lxxvi., p. 345.

Influence of Annealing.—As is well known, annealed wires have a less resistance than hard-drawn wires; but the variation of resistance according as the wires are annealed or hard drawn differs considerably for different materials. For silver it is as much as 10 per cent., whereas for copper it is less than 3 per cent.

I have made observations from time to time on the resistance value of specimens of hard-drawn copper wire, all pieces of the same coil, which was sent me in 1889 by Messrs. Bolton and Son. Given the results of these measurements, it will be seen that a hard-drawn wire seems to fall in resistance with lapse of time; the coil of wire has been left laying in the laboratory, and has not been treated with any special care :

Date.	Temperature.	Resistance of wire one metre long weighing one gramme.
July, 1890	18deg.	$1,528 \times 10^5$
August 26, 1891	18deg.	1,525
March 7, 1892	18deg.	1,522
January, 1894	18deg.	1,520
July, 1894	18deg.	1,519

The fall in resistance is small, and for the period of nearly five years does not amount to more than one-third per cent. I have, for the sake of comparison, made a measurement of the resistance of a specimen of annealed copper wire sent me by the same firm, and for this the resistance value is identical with that obtained at a previous date :

Date.	Temperature.	Resistance of wire one metre long weighing one gramme.
October, 1889	18deg.	$1,488 \times 10^5$
July, 1894	18deg.	1,487·8

This, on the whole, is what one would expect. In the case of wires of other material the change would probably be greater, as the difference of resistance between annealed and hard-drawn copper wires is less than that for wires of other materials.

In my previous communication a method* of annealing was described which gave satisfactory results; the wire was packed in asbestos or fine carbon in a copper vessel, and heated for 24 hours.

The following results, amongst others, were obtained :

Hard-drawn at 18deg	Annealed. 18deg.	Difference.
$1,527 \times 10$	1,489	·39
1,526	1,488	·38

Matthiessen's values are :

1,550	—	—

Messrs. Swan and Rhodin give for the values of the specific resistances :

1,720	1,680	·40

I have recently been annealing copper wires by heating them in boiling paraffin (220deg), and at this temperature, after slow cooling, the wires seem to be completely annealed.

1,526	1,486	·40

A wire sent me as annealed gave the result :

—	1,488	—

This wire was then hardened and reannealed, and gave the above-described value :

—	1,489	—

Either of these two methods seemed to give satisfactory results. But for annealing silver wires completely the temperature of the paraffin bath is not sufficiently high, but from the results of my measurements for silver, for which the influence of annealing is very considerable, it could be seen that the results given for the first method are very consistent.

Silver.

Many of the older measurements for resistances and conductivities are expressed in terms of the resistance of pure silver. This was the case with Matthiessen's earlier results. Some measurements, therefore, made on silver wires are given, together with the results obtained by Matthiessen and Messrs. Dewar and Fleming for the sake of comparison.

Several samples of silver wires were supplied me by Messrs. Johnson and Matthey. One of these was stated to be absolutely pure. The results are expressed for wires weighing one gramme per metre :

	Hard-drawn.	Annealed.
Silver I.	(*a*) $1,816 \times 10^5$	$1,739 \times 10^5$
	(*b*) 1 814	1,741
	(*c*) 1,816	1,721
Silver II.	1,799	1,722
Silver III. pure	(*a*) 1,777	1,666
	(*b*) 1,773	1,666
	(*c*) 1,767	—

The difference between the values for the hard-drawn wires is probably due to the fact that they had to be further drawn down after I had received them to enable me to measure them on my bridge.

Matthiessen's values.	For wire one metre long weighing one gramme.	R. per c. cm.
Hard-drawn	$1,779 \times 10^5$	1,694[1]
Annealed	1 639	1,561

[1] Using the value 10·5 as the specific gravity of silver.

Messrs. Dewar† and Fleming give as the value for an annealed pure silver wire, 1,468 C.G.S. at 0deg. C., with the temperature coefficient of ·004; the value at 18deg. is, therefore, for the specific resistance, 1,574.

For most of the wires which I measured I determined the specific gravity. For the wires silver I. there is practically no difference between the values obtained for the annealed hard-drawn wires, the values varying from 10·496 to 10·511.

For the wires silver III. the values varied from 10·49 to 10·50; using the mean value, 10·495, I get for the specific resistances the following values :

	Hard-drawn wire.	Annealed.
Specific resistance in C.G.S. units at 18deg.	1,689	1,587

In the case of copper,‡ with increase of purity, there is a

* B.A. Report, 1890, p. 126. † *Phil Mag.*, vol. xxxvi. ‡ B.A. Report, 1890, p. 196.

Digitized by Google

decrease in the difference in resistance between annealed and hard-drawn wires. With silver the reverse is the case :

Silver	I. Difference	75
	II. ,, ...	77
	III. ,, ...	107

The value that I obtained for the hard-drawn wire is very nearly the same as that given by Matthiessen, but he obtained a greater decrease in resistance on annealing. He states* that for different pieces of the same wire there was a variation of from 6 per cent. to 10 per cent., so that the difference between his value and that which I have obtained for the sample of pure silver is not greater than might be expected.

The considerable variations in all the values given above make it clear that the value of the specific resistance depends not simply on the purity of the material, but on a number of other factors, which will be different in the cases of different wires of the same material, and that, therefore, we cannot expect to attain to any great degree of accuracy in the determination of specific resistances.

WOODHOUSE AND RAWSON UNITED, LIMITED.

We quote the following from the *Financial News* of Tuesday's date :

"On Thursday last Mr. F. L. Rawson attended at Bankruptcy-buildings, before Mr. Registrar Hood, in order to put in his statement with regard to the affairs of the above Company. He was asked no questions by the Official Receiver on this statement. He said that he would like to thank the Official Receiver and his officials for the courtesy that had been shown to him since it had been found that there were no grounds for the statements that had been made against him. Mr. Rawson further asked for payment of his costs incurred during the public examination, and was requested to make such application upon resumption of the usual sittings.

"Mr. Rawson's statement consists of 129 pages of foolscap, together with many documents giving proof of various remarks made by him. With regard to the return of the guarantee fund, he showed that, even after allowing for no profits being made the last year, the surplus profits the first year were so large that the whole of the guarantee fund would have had to be returned—this being by the terms of the agreement. He gave particulars to show that had the guarantee fund not been returned in debenture stock, the debenture-holders, shareholders, and creditors of Woodhouse and Rawson United would have been worse off even under the special circumstances that had arisen. He went fully into the prospects of the Company, and claimed that the directors were not then over-sanguine. He put in various documents and letters as to the value of the different securities held by the Company at that date, and gave details of the 10 companies in which the United held securities, stating that three shareholders were chosen at the meeting in 1891 to examine the securities held by the Company, and they were perfectly satisfied. Most of the securities had a Stock Exchange quotation, none were taken over the market price, and in two cases they were taken below. Witness then put in a large amount of correspondence to show the care with which the valuations had been made, also correspondence to show that both the chairman (Sir Rawson Rawson) and he had gone carefully into the valuation of plant and stock, and had insisted upon large reductions, notwithstanding what the managers stated with regard to the values. As to the sole valuation which had been challenged—that of Kidsgrove—witness gave details to show that the plant and stock had been properly and carefully valued at the amount taken in the balance-sheet. Woodhouse and Rawson United had dealt with their patents in a conservative way, as they only put in new patents at the cost of the patent fees, and in 14 years the total cost of their patents would have stood in their books at under £2,000, whereas, in the ordinary course of business, by that time they would have considerably improved in value. He then dealt with the evidence of Mr. Stutchbury, and gave 17 instances in which he alleged that the statements of that witness were incorrect, referring to various documents for confirmation, and proving several of them from the witness's own letters at that date.

"With regard to Mr. Stutchbury's analysis of trading in 1890 and 1891, Mr. Rawson gave a large number of instances of mistakes in these analyses, and claimed that in 1890, when he had charge of it, there was a profit in every branch of the industrial business except one small one. Quotations were put in from various reports of meetings to show that the position with regard to industrial profits and profits made from the patent side of the business had been made clear to the shareholders. He stated that the industrial business of the Company largely increased in the first year, and had doubled by the end of the second year. Going into details of his interviews with Mr. Pixley, Mr. Rawson stated that that gentleman was most conservative and careful, and that all his proposals with regard to writing off and reducing valuations of plant, stock, patents, etc., were carried out; that Mr. Pixley had admitted that, owing to the Company's contract with him (Mr. Rawson) and Woodhouse and Rawson, Limited, they were obliged to value all the securities, which had been properly done, and to put them in the balance-sheet at the price of such valuation ; that in 1891, if this had not been done and the next year had turned out as well as was expected, even the shareholders who retained their holding in the Company would have had a right to complain, as it would have brought profits properly belonging to the year 1891 into the year 1892, and so largely increased his (Mr. Rawson's) commission. Witness drew attention to the large reserves after payment of this dividend, the amount shown in the books being £46,996, and stated that if they had not written off various items which they were allowed by the articles of association to carry forward, and had put in the shares at the quoted prices, instead of in some instances below those prices, this amount would have been increased to £66,362. Even if the value of the shares in the Phœnix Trust and the Epstein Company had been taken at Mr. Stutchbury's cost-price estimate, and the other unquoted shares at present break-up prices, it would have left a balance to reserve of £17,296, or £36,662 including the additional amounts. He did not see any difference between paper profits which were not realised and profits represented by plant or stock, for if the securities were in companies intrinsically sound, as was the case in Woodhouse and Rawson United, they improved in value, whereas plant and stock deteriorated. He gave details of the sales of shares and debentures amounting the previous year to over £100,000.

"With regard to the suggestion that he had over estimated the profits in the first year in order to get a larger commission, he gave instances of various sums, amounting to over £5,000, which had not been treated as profits that year, but which were profits, and turned out to be so the following year ; whilst the directors need not have written off that profit and loss the large sums they had. All the shares that they held at the date of the balance-sheet that year were actually sold and paid for before the dividend was paid, and they had cash profits sufficient to pay the dividend. With regard to the Phœnix Trust, he stated that Woodhouse and Rawson United refused to do a financial business, and that this company was formed to underwrite various companies, from the formation of which Woodhouse and Rawson made a profit which they would not otherwise have done. In showing that the directors were not unduly swayed by him he stated that the industrial business was taken out of his hands after the first year against his wish, and later, when it was being put into the hands of Mr. Stutchbury, he objected to the arrangement on the ground that Mr. Stutchbury had not had sufficient experience, and he (witness) offered personally to pay half the cost of a competent manager. Having given a number of instances where he had sacrificed himself in order to help the various companies, and his reasons for so doing, Mr. Rawson went into particulars to show that the United Company did not do a financial business, there only being five pieces of business that could be called financial, only two of these being strictly so-called. They never underwrote, never bought any shares in the market, never discounted acceptances for others, did not lend money, and, in fact, did not do a financial business in any way. Other electrical companies had just as much to do with the promotion of companies from which they made profits by undertaking contracts for works as Woodhouse and Rawson United, who had got profits from the sale of patents to four different companies. He then dealt with the report of the committee of consultation, giving 22 instances of statements made by them, nearly all of them of importance, which had turned out in the public examination to be incorrect, and concluded by giving the points against the directors which had been raised during the examination, and summarising the answers, which, he claimed, fully explained and refuted them."

ELECTRIC LIGHTING PROVISIONAL ORDERS.

BOARD OF TRADE REPORT.

We give below the report by the Board of Trade respecting the applications to and proceedings of the Board of Trade under the Electric Lighting Acts, 1882 to 1890, during the year ended June 29, 1894. The following is a list of the applications for provisional orders since the date of the last report, together with the title of order and description of area, the names of promoters, and how dealt with by the Board of Trade :

Aberdare Electric Lighting Order. A Portion of the District of the Aberdare Local Board.—J. C. Howell, Limited.—Order granted.

Barrow-in-Furness Corporation Electric Lighting Order. The Borough of Barrow-in-Furness. — The Corporation. — Order granted.

Bedford Electric Lighting Order. The Municipal Borough of Bedford. Bedford Electric Light Company, Limited.—The promoters failed to produce the consent of the local authority, or to satisfy the Board of Trade that it should be dispensed with, and the Board of Trade refused to grant the order.

Birmingham Electric Light and Power Order. A Portion of the City of Birmingham —Birmingham Electric Supply Company, Limited.—Order granted.

Buxton Electric Lighting Order. The Urban Sanitary District of Buxton.—The Local Board.—Order granted.

Chelmsford Electric Lighting Order. The Borough of Chelmsford.—Crompton and Co., Limited.—Order granted.

Chepping Wycombe Electric Lighting Order. The Municipal Borough of Chepping Wycombe.—The Corporation.—Order granted.

Chesterfield (Corporation) Electric Lighting Order. The Borough of Chesterfield.—The Corporation.—Order granted.

Phil. Trans., 1862, p. 7.

Digitized by Google

Clonmel (Corporation) Electric Lighting Order. The Borough of Clonmel and portions of the District of the Clonmel Union.—The Corporation.—Order granted.

Collier-Marr Moss Side Electric Lighting Order. The Urban Sanitary District of Moss Side.—Collier-Marr Telephone and Electrical Manufacturing Company, Limited.—Order granted.

Grimsby (Corporation) Electric Lighting Order. The Borough of Grimsby.—The Corporation.—Order granted.

Guildford Electric Lighting Order. The Borough of Guildford.—Holloway Electricity Supply Company, Limited.—The local authority consented to the grant of the order subject to certain conditions as to purchase. These conditions the promoters were unable to accept, and the Board of Trade, for the reasons stated in the special report made by them and presented to Parliament, decided to grant the order.

Harrow Electric Lighting Order. The Urban Sanitary District of Harrow.—The Local Board.—Order granted.

Leyton Local Board Electric Lighting Order. The Local Government District of the Leyton Local Board.—The Local Board.—Order granted.

Monmouth Electric Lighting Order. The Municipal Borough of Monmouth.—The Corporation.—Order granted.

Oswestry Electric Lighting Order. The Borough of Oswestry.—Oswestry Electric Lighting and Power Company, Limited.—Order granted.

Peterborough Electric Lighting Order. The Municipal Borough of Peterborough.—The Corporation.—Order granted.

Plymouth Corporation Electric Lighting Order. The Borough of Plymouth —The Corporation —Order granted.

St. Austell Electric Lighting Order. The District of the St. Austell Local Board.—Veale and Co, Limited —Order granted.

St. Helens Corporation Electric Lighting Order. The Borough of St. Helens.—The Corporation.—Order granted.

Shropshire Electric Lighting Order. A Portion of the Borough of Shrewsbury.—Shropshire Electric Light and Power Company, Limited —Order granted.

Stirling Electric Lighting Order. The Royal Burgh of Stirling.—Caledonian Electric Supply Company, Limited.—The promoters failed to produce the consent of the local authority or to satisfy the Board of Trade that it should be dispensed with and the Board of Trade refused to grant the order.

Wakefield Corporation Electric Lighting Order. The City of Wakefield.—The Corporation.—Order granted.

West Hartlepool Electric Lighting Order. The Municipal Borough of West Hartlepool —The Corporation.—Order granted.

Yeadon Electric Lighting Order. The Urban Sanitary District of Yeadon —The Local Board.—Order granted.

The County of London :

Crystal Palace District Electric Lighting Order. Portions of the District of the Beckenham Local Board; the Borough of Croydon; the Parish of Lambeth; the District of the Lewisham District Board of Works; and the Parish of St. Giles's Camberwell.—Crystal Palace District Electric Supply Company, Limited —Order granted.

Of these applications (26 in number) 15 were made by local authorities and 11 by companies, only one relating to the county of London.

Bills Nos. 1 and 2, to confirm the orders relating to Barrow-in-Furness, Buxton, Chepping Wycombe, Chesterfield, Grimsby, Harrow, Leyton, Monmouth, Peterborough, St. Austell, St. Helens, and West Hartlepool were introduced into the House of Commons on April 16. Bills Nos. 3 4, and 5 to confirm the orders relating to Aberdare, Birmingham. Chelmsford, Clonmel, Crystal Palace district, Guildford, Moss Side (Collier-Marr). Oswestry, Plymouth, Shropshire (Shrewsbury), Wakefield, and Yeadon were introduced into the House of Lords on the following dates—viz., No. 3 on April 30, No. 4 on May 4, and No. 5 on May 7.

The Bills to confirm provisional orders granted by the Board of Trade last year, which were before Parliament at the date of the last report, all received the Royal assent.

In the following instances the Board of Trade have, since the date of the last report, approved deeds transferring to limited companies the powers, duties, and liabilities (with certain exceptions) under provisional orders granted to local authorities :

Aberystwith Electric Lighting Order, 1892. Originally granted to the Corporation of Aberystwith. Transferred to the Bourne and Grant Electricity Supply Company, Limited.

Chiswick Electric Lighting Order, 1891. Originally granted to the Local Board for the District of Chiswick. Transferred to the Bourne and Grant Electricity Supply Company, Limited.

Dover Electric Lighting Order, 1890. Originally granted to the Corporation of Dover. Transferred to the Dover Electricity Supply Company, Limited.

Scarborough Corporation Electric Lighting Order, 1891. Originally granted to the Corporation of Scarborough. Transferred to the Scarborough Electric Supply Company, Limited.

LICENSES.

The following applications for licenses have been received since the date of the last report, and have been dealt with in the manner shown below :

The Corporation of Bournemouth. The Borough of Bournemouth.—License granted April 16, 1894. (The license authorises the supply of energy for certain public purposes only).

The British Insulated Wire Company, Limited. The District of the Prescot Local Board.—Still under consideration.

The Collier-Marr Telephone and Electrical Manufacturing Company, Limited. The Urban Sanitary District of the Moss Side Local Board.—The promoters subsequently applied for a provisional order, and the application for the license was not proceeded with.

Of applications for licenses referred to in previous reports, that of the Shropshire Electric Light and Power Company, Limited, was granted on August 10, 1893, and that of the Crystal Palace District Electric Supply Company, Limited, on August 21, 1893. The Dundalk Electric Lighting License, 1886, the original term of which expired on July 1, 1893, was renewed by the Board of Trade for a period of three years from that date. Appended is a list of the provisional orders confirmed by Parliament (prior to the present session) and of the licenses granted by the Board of Trade since the passing of the Electric Lighting Act, 1882, showing those which have since been revoked or repealed.

THE RATING OF MACHINERY.

It has been a matter for comment that none of the semi-agricultural unions in the neighbourhood of the Chard Union have attempted to follow the example of the Chard Board of Guardians in trying to rate the machinery of the few scattered and struggling factories established in their districts. The very qualified success which attended the Chard authorities is probably the correct explanation of this state of things.

At last, however, the Tiverton Assessment Committee have been induced to attempt to increase the ratable value of the union by attacking the manufacturers who have for years brought business into the district and given employment to large numbers of the population.

Before the increased assessments came before the Assessments Committee, the clerk issued to every member a circular letter showing how the assessments in the Chard Union had been increased.

Among the firms attacked were Messrs. Fox Bros., of Wellington and Uffculme, who are among the founders of the Machinery Users' Association, which arose out of the notorious case of Fox and Co. *v.* Chard Union. The firms affected combined to resist the attack, and placed the matter in the hands of the Machinery Users' Association.

The Assessment Committee, however, remained obdurate, and, contemptuously declining an offer of arbitration, referred the appellants to their legal remedy of an appeal to the Quarter Sessions. July 31 was fixed by the Court as a special day to try the cases, but the Assessment Committee did not put in an appearance to support their valuations.

The appellants, who had had all the trouble and expense of getting up their cases, were duly represented by Mr. Edward Boyle (specially retained) and Mr. Cleare. The chief evidence relied upon was that of Mr. Humphreys-Davies, the consulting surveyor to the Machinery Users' Association, who was supported by Mr. Sheldon, J.P., and Mr. R. Howard Leaker, of Bristol. The Court, after going carefully into the merits of each case, allowed all the appeals with costs against the respondents.

This result is very encouraging to machinery users, and shows the value in these cases of combined action for mutual defence. It will be remembered that the difficulties as to the rating of machinery arose in the neighbouring town of Chard about seven years ago, and it is noteworthy to find that the Machinery Users' Association, which has been fighting the battle in the interval in all parts of the country, has now inflicted a signal defeat upon the Tiverton authorities in their attempt to reopen the contest in the West of England.

COMPANIES' MEETINGS.

CUBA SUBMARINE TELEGRAPH COMPANY, LIMITED.

The forty-sixth ordinary meeting of this Company was held on Wednesday at the offices, 58, Old Broad-street, under the presidency of Mr. T. Greenwood.

The **Chairman** moved the adoption of the report, which recommended a dividend on the ordinary shares at the rate of 8 per cent. per annum, leaving £3,429 to be carried forward. He said that the directors were pleased to be able to present so favourable a report. The expenditure and receipts were nearly the same as in the corresponding period of last year. Fortunately, they had had no repairs during the past half-year, so that that was the second period they had passed without repairs, while they had had payments in the previous year of £1,647 for repairs. They had also added £1,000 to reserve, as compared with £1,500 last year, against losses by deposits with banks, the result being that they were able to increase the amount carried forward to the reserve fund by £2,500, and also to improve their balance carried forward to the next half-year. That would be highly satisfactory to the shareholders, and they would have no difficulty in approving of the report and accounts submitted.

Mr. C. W. Parish seconded the motion, which was adopted.

THOMAS PARKER, LIMITED.

The statutory meeting of this Company took place last Friday at the registered offices in Wolverhampton, Mr. C. T. Mander (the chairman) presiding. After the usual formal business, a **Shareholder** enquired how the matter stood with the Electric

Digitized by Google

Construction Company in respect to the Eickemeyer dynamo winding patents. The **Chairman** reported that the purchase of the Eickemeyer patents had been completed, and that the legal proceedings commenced by the Electric Construction Company remained as they were, but that his Board were considering the question of granting a license to the Electric Construction Company for the use of those patents on terms to be agreed. He informed the meeting that the works of Thomas Parker, Limited, were rapidly approaching completion, and that there was every prospect of the Company at once entering upon a large and remunerative business.

CONTRACTS FOR ELECTRICAL SUPPLIES

CONTRACTS OPEN.

Woodbridge.—The Local Board require tenders for street-lighting for 12 months.

Dundee.—Messrs. Urquhart and Small, of 17, Victoria-street, Westminster, S.W., are authorised by the Dundee Gas Commissioners to invite tenders for a steam-engine and dynamo, in connection with the supply of electric light. Copies of the specification and form of tender can be obtained from the above-mentioned firm. Tenders will be received by them on or before the 30th inst.

Birmingham.—Tenders are invited for the electric lighting of the glasshouses, etc., at the Botanical Gardens, Edgbaston, Birmingham. A copy of the specification may be obtained from Messrs. Henry Lea and Thornbery, 38, Bennett's-hill, Birmingham. Tenders must be sent in on or before September 1, addressed to Prof. Hillhouse, M.A., hon. sec., Birmingham Botanical and Horticultural Society, Botanical Gardens, Edgbaston, Birmingham.

RESULTS OF TENDERS.

London, W.—The tender of Messrs. Graham and Biddle, at £320, has been accepted for electric light fittings and heating apparatus, for Mr. Stephen Rath, at 32, Park-lane.

Hull.—On Monday the Hull Corporation Electric Lighting Committee accepted Mr. G. Strachan's tender for Kilnhurst coal at 13s. 8d. per ton of 21cwt. A new dynamo and engine were ordered to meet the growing requirements of the electric light station. These machines will be equal to supplying 6,280 8-c.p. additional lamps. The engine is from Messrs. Willans and Robinson, of London, at a cost of £1,247, and the dynamo from Messrs. J. H. Holmes and Co., of Newcastle, at a cost of £1,230. The steam-piping is being ordered in Hull.

Cheltenham.—The Electric Lighting Committee of the Town Council recently received for the supply of transformers nine tenders, which were handed to the electrician to examine and report. They were:

Brush Company	£394	15	0
Crompton and Co.	450	0	0
Electric Construction Company	455	10	0
Johnson and Phillips	468	0	0
Slade, Templeton, and Co.	500	0	0
Swinburne and Co.	522	0	0
C. A. Parsons and Co.	606	12	0
Siemens Bros. and Co.	677	0	0
J. Fowler and Co.	783	5	0

The electrician's report was subsequently considered, and the tender of the Brush Company was recommended for acceptance. The Town Council have since adopted this recommendation.

Electro-Chemical Company, Limited.—The tenders received for engines and dynamos for the first section of this Company's plant—viz., 1,000 e.h.p. with water consumption guaranteed under a penalty of £1,000 per pound of water, were as follows: Parsons and Co, two steam-turbines 15¾lb., 1,100 e.h.p., £4,800; Yates and Thom, horizontal engines and Holmes's dynamos 15¼lb., with extras, about £8,300; Willans and Robinson, four engines with Holmes's dynamos £9,700, four engines with Crompton's dynamos £9,950, four engines with Siemens's dynamos £9,980, four engines with Mather and Platt's dynamos £10,100; Electric Construction Company, four Willans engines and E.C.C. dynamos, 17·384lb., £10,023; Easton and Anderson, 17¾lb. (with extras) £8,816, Willans engines £10,850 to £11,140; Musgrave and Sons, engines only, 13½lb. per indicated horse-power, £6,224; Crompton four Willans engines, 17½lb., £10,780 to £11,140; Johnson and Phillips, dynamos only, £2,675. The water consumption is under 160lb. per square inch, and includes steam used for feed and condenser pumps. Messrs. Parsons and Co.'s tender was recommended for acceptance by the consulting electrician (Mr. Swinburne), and has been accepted by the directors. Mr. T. Beeley, of Hyde, Manchester, has secured the contract for the boilers.

Thetford.—The Town Council have accepted the gas company's tender for lighting the public lamp as usual. The committee had recommended an all-night lamp at the Bell corner, but as St. Peter's clock has been lighted with the electric light with great satisfaction, it was suggested that if instead of putting it out at 11.30 p.m. it could be continued till daylight it would dispense with the gas lamp and be cheaper, and this was recommended to the Lighting Committee to adopt, if arrangement can be so made. Permission was given the electric light and power company to carry some of their cables underground.

BUSINESS NOTES.

Margate.—Two companies propose to apply for electric lighting powers.

Arbroath.—The Corporation intend to oppose the application of the Northern Electric Supply Company.

Dewsbury.—The expenditure of £2,150 for lighting the workhouse by electricity has been sanctioned.

Western and Brazilian Telegraph Company.—The receipts for the week ended August 17 were £2,106.

Derby.—The St. John's Schools, which have been rebuilt at a cost of £2,000, will be lighted by electricity.

Dover.—The breaking up of the streets by the electric light company engaged the attention of the Town Council last week.

Broadstairs.—The Local Board do not intend to oppose the application of the County of London and Brush Provincial Company.

St. Saviour's, Southwark.—Messrs. Strode and Co. have obtained the contract for the electric lighting of the baths and washhouses.

Ship-Lighting.—The Japanese steamer "Islam," which has been detained on the Clyde under the Foreign Enlistments Acts, is lighted electrically.

Sheffield.—Mr. Edmund Welding intends to build a new theatre of varieties on the site of the Grand Theatre. It will be lighted by electricity.

Coventry.—The City Council have affixed the corporate seal to mortgages of the general district fund for raising £2,000 at 3½ per cent. for the electric lighting.

Personal.—Messrs. E. W. Dickenson and Mr. W. J. Piling have been appointed assistants to Mr. John H. Rider, electrical engineer to the Bolton Corporation.

Barrow-in-Furness.—The Town Council having obtained a provisional order, it is expected that a committee will shortly be appointed to push the matter forward.

West India and Panama Telegraph Company.—For the two weeks ended August 15 the receipts show a decrease of £225 as compared with the corresponding period.

Thurstonland.—The Local Board have granted permission to Mr. Mitchell to erect the necessary wires over the road at Brockholes for supplying electric light to his house.

Speller and Co., Limited.—This Company has been registered, with a capital of £5,000, to carry on business as manufacturers of lamps, etc., and of gas and electric light fittings.

Ariel Arc Lamp Syndicate, Limited.—This Company has been registered, with a capital of £20,200, in £10 shares, to carry on business as electricians and suppliers of electricity.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending 19th inst. amounted to £1,126, as compared with £822 in the corresponding week of last year.

Submarine Telephony.—It is stated that a company has been formed to develop a subaqueous telephone, and by means of gongs communicate between ships without the intervention of wires.

Lancaster.—The trustees of the Palatine Hall have decided to have the building lighted by electricity, and the arrangements of Mr. Barnard, the borough electrical engineer, have been adopted.

Rollason's Wind Motor.—A meeting of the shareholders of the Rollason's Wind Motor Company was held on Monday at Winchester House, Old Broad-street, E.C. The proceedings were private.

Llanelly.—The arrangements for lighting the Dafen Tinplate Works by electricity have been completed by Messrs. J. C. Howell and Co., and the works were illuminated by electricity for the first time on Monday.

Leeds.—A new building for the Yorkshire Penny Bank has been opened, with offices above. Electric lighting has been adopted throughout. Messrs. Dixon and Son, of Leeds, have done the electric light wiring.

Brush Electrical Engineering Company, Limited.—This Company notify that the transfer books of the 4½ per cent. debenture stock of the Brush Electrical Engineering Company, Limited, will be closed from August 25 to September 3, inclusive.

Appointments Vacant.—The Electric Lighting Committee of the county borough of Halifax require the services of an assistant electrical engineer and a foreman to take charge of the underground mains. Further particulars will be found in our advertisement columns.

Church-Lighting.—Messrs. Bennett and Druce, of Preston, have been instructed to instal the electric light in the Saul-street Chapel, Preston, together with the adjoining vestries, schoolrooms, classrooms, etc. The current will be taken from the supply company's mains.

Bath.—Messrs. Alex. McTavish and Co., of Old Bond-street, have secured the contract for the electric lighting of Messrs. Charles Bayer and Co's new factory at Oldlands Common, near Britton. The plant will comprise an engine, boiler, dynamo, and wiring for 120 16-c.p. lamps.

Cardiff.—On Tuesday evening a meeting of the Machinery, Electricity, and Local Industries Committee of the Cardiff Exhibition for 1895 was held at the Town Hall. The committee considered in detail the plans for their portion of the exhibition, and prepared a report to be laid before the general council.

Digitized by Google

London-Platino Brazilian Telegraph Company, Limited.—The half-yearly coupons, due on September 1 next, of the £100,000 6 per cent. debentures, will be paid on and after that date by Messrs. Glyn, Mills, Currie, and Co., Lombard-street, E.C.

Carlisle.—The County of London and Brush Provincial Electric Lighting Company have given notice of intention to apply to Parliament next session for a provisional order to supply Carlisle with the electric light. The subject of the electric light is also under the consideration of the Gas Committee of the Town Council.

City and South London Railway.—The receipts of the Company for the week ended August 19 were £861, against £862 for the corresponding week of 1893, or a decrease of £1. The total receipts for the current period of the present half-year amount to £6,064, as against £5,928 in the corresponding period of 1893.

Warminster.—Owing to the success of the electric light on the fountain in the Market-place, it has been suggested to the Local Board that six more lights should be placed between the fountain and the obelisk, the cost of the necessary plant being estimated at £184. The matter has been referred to a committee for consideration and report.

Richmond (Surrey).—The Town Council have passed the payment of £105 to Messrs. Urquhart and Small for superintending the erection of the electric lighting works and the laying of mains, now completed. Councillor Heasler has undertaken to supply a statement showing the total expenses of the town in connection with the electric light.

Larne.—The Larne Town Commissioners have received a letter from Mr. J. W. M'Ninch, solicitor to the Board, enclosing a letter from Mr. J. D. A. Norris, receiver and manager for Messrs. J. E. H. Gordon and Co., Limited, electrical contractors for the town of Larne, in which Mr. Norris stated the agreement for the public lighting had been accepted by the Court.

Taunton.—Mr. Harold W. Couzens, the electrical engineer to the Town Council, reported to that body last week that during the past quarter the improvements and alterations suggested by Dr. Fleming had been completed, and had been examined and approved of by him. The new consumers connected to the mains during the past quarter make a total equivalent of 219 16-c.p. lamps.

Slough.—The Rural Sanitary Authority have received a letter from the Board of Trade enclosing a copy of a letter from the town clerk of Windsor applying on behalf of the Corporation for the revocation of the Windsor Electric Supply Order, 1890, and stating that, subject to any representations the Authority might wish to make, they proposed to revoke the order forthwith. The members resolved to take no further action in the matter.

Stafford.—The Town Council have accepted the tender of Messrs. Hart, Son, and Peard, at £47. 15s. 6d., for the supply of ornamental cast-iron window-frames at the electric lighting works, instead of the one sent in by the General Iron Foundry Company. A commemoration stone, bearing the Mayor's name and the date, is to be placed inside the works, and a tablet with the name of Alderman W. H. Peach, the chairman of the committee, is to be inserted in the chimney stack.

Sale of Stock.—In connection with Woodhouse and Rawson United, Limited, the whole of the stock, now at 88, Queen Victoria-street, E.C., and at Bradford, Birmingham, Glasgow, and Chiswick, consisting of dynamos, motors, distributing boards, switches, lamps, holders, cables, casing, electric and steam launches, and every requisite for electric lighting, is now open for inspection, and is for sale until September 30. Mr. F. D. Leslie, receiver and manager, 74, Coleman-street, E.C., will furnish particulars of the sale.

The War in the East.—The ss. "Islam" belonging to a Japanese firm, which has been seized on a warrant issued by the Foreign Secretary to the British Government, is being elaborately and carefully fitted up thoroughout with Messrs. Baird, Thompson, and Co.'s latest improved mechanical system of ship ventilation which is claimed to be capable of changing the whole atmosphere of the ship once every minute if necessary. This system can be used with closed hatches and everything battened down, is perfectly weatherproof, and under perfect control.

Wolverhampton.—The Corporation scheme for illuminating a central area of Wolverhampton with the electric light is nearing completion, the lines having been laid beneath the footways, and the generating station will be finished shortly. Out of the 22 competitors, Messrs. Fletcher and Hurst, of Burnley, have secured the contract for putting the necessary wires and the selected fittings into the municipal buildings. The amount of the tender, which was the lowest, was £609. 11s. The tender for the pendants and other fittings has not yet been agreed upon.

Worcester.—The Watch Committee have resolved to ask the Mayor (Mr. G. H. Williamson) to perform the ceremony of opening the electric light works at Powick on October 11. As ladies will be present at the exhibition at the Public Hall, it will be gracious to ask the Mayoress to open the exhibition. The Mayor observed that the Mayoress and himself would be pleased to do anything calculated to benefit the city. The Council have authorised certain alterations and improvements in the wiring and fittings of the Guildhall buildings for the electric light, at an additional cost of £18. 16s. 2d., and similar alterations at the Public Hall, at an additional cost of £14. 16s. 2d.

St. Austell.—The Local Board have had mentioned to them by Mr. B. Andrew that there had recently been many complaints by the inhabitants of the town being badly lighted. The matter was referred to the Lighting Committee, with a view to a rearrangement of the time of lighting the lamps. A letter from Messrs. Veale and Co. offered to supply the fountain lamp in Fore-street with an electric light at the rate of 2½d. per hour, a reduction of ½d. During the past year the hours during which the light had been used numbered 1,200, and it was pointed out that if the number was reduced to 853 at the stipulated price the cost would be £8 per year, the sum which the Board decided to pay for the light. The light would be 200 c.p. The offer was accepted.

Bromsgrove.—As mentioned in our last issue, the Town Local Board at their last meeting decided to consult the ratepayers as to the application of Messrs. Hemming and Co., Birmingham, for permission to lay down plant for electric lighting in the district, and in consequence notice was issued by Mr. Jeffries, chairman of the Board, convening a public meeting of ratepayers to be held at the Town Hall at 11 a.m. on Monday last, "to consider the subject of lighting the town by electricity." At the time appointed there was a considerable attendance of tradesmen, working-men, and others. Mr. D. Laing, who was voted to the chair, read letters from Messrs. A. Dipple, G. Bown, and C. Field (member of the Board) expressing dissatisfaction at the meeting being called at an inconvenient hour, and suggested evening as a more suitable time. The Rev. E. Vine Hall proposed the following Thursday (yesterday), and after other propositions had been made this was carried.

New Installations.—Messrs E. H. Berry and Pope, of Burnley, have received the contract for the electric lighting of the Corporation Technical School, Nelson. They have also received instructions for the electric lighting of the Empress Hotel, Burnley, where about 150 lights are to be installed; the Royal Oak Hotel and the Rose and Thistle Hotel, Burnley; besides several smaller installations in Southport, Nelson, Burnley, etc. The firm have lately supplied and fixed a gas-engine and dynamo and change-over switchboard for the G.W.O.O.F. Club, Keighley Green, Burnley. The club authorities are able to use either their own plant or the Corporation supply. The gas-engine is by Messrs. Tangyes, Limited, and capable of giving 16 b.h.p. The dynamo has been made by Messrs. Rosling and Matthews, of Bradford. The firm have also installed the electric light in the Union Club, Burnley, and the contract for supplying and fixing the electric light fittings for the art gallery, free library, and museum, for the Blackburn Corporation.

Hammers and Heating Forges.—Mr. H. F. L. Orcutt, of 145, Cannon-street, E.C., has sent us a copy of the illustrated list of hammers and heating forges made by Messrs. L. Loewe and Co., of Berlin. The drop hammers may be used to advantage in place of steam hammers for forging by hand. The cushioned helve hammer is recommended as an efficient and durable tool for making circular-formed stampings and for gun work, etc. The motion is imparted to the hammer through an eccentric and an adjustable connecting-rod. The eccentric is driven by means of a belt and a tightener, which is operated by a foot lever. The rapidity and weight of the blow depends upon the tension given the belt by this lever. A brake, which is connected with the foot lever, arrests the motion of the hammer as soon as the foot lever is released. The anvil rests on a separate foundation, so that the other parts of the machine are free from vibration. The forges are intended for heating a number of pieces at a time, where stampings are made from the ends of rods of material.

Monmouth.—A special meeting of the Corporation was held on Monday to consider the report of Messrs. Bramwell and Harris, C.E., London, as to the best and least expensive system of drainage and electric lighting in the borough. The report deals first with a scheme for sewage alone, which it is estimate would cost £12,000, equal to a rate of 1s. in the £ for 30 years. The second part of the report deals with a combined scheme of electric lighting and drainage, which would increase the first outlay to £17,600, but deducting the present cost of gas for public lamps, and adding the earnings of the 2,500 8-c.p. incandescent lamps (or their equivalent) provided for in the scheme for lighting public places and for private use, the work can be carried out at a cost of only 7d. in the £. The combined scheme was unanimously adopted, and a committee of four, with the Mayor as president, was appointed to arrange the details. The Chairman read a letter from Lord Llangattock, offering £100 a year for lighting the Hendre House by electricity, his lordship paying all cost of laying the mains.

Mill-Lighting.—The Chancelot Flour Mills, Edinburgh, which have been erected by the Scottish Co-operative Wholesale Society, Limited, are lighted by electricity. A small compound engine drives the dynamos, which are of 30 units each, made by Messrs. Mavor and Coulson, of Glasgow. Each machine is capable of lighting up the whole mill, the installation of which consists of 500 incandescent lamps of 16 c.p., and eight outdoor arc lamps. The wiring throughout the mill is on the concentric wire system. Messrs. E. H. Berry and Pope, of Burnley, have received instructions for a complete installation for the electric light for the Monton Mills Company, Sabden, Lancashire. This mill is being lighted throughout, including the weaving-shed. Two dynamos will be used, which will be driven from the large engine, and a 50-light machine will be driven from a donkey engine. The total number of lights to be installed is over 400. This firm have also received instructions to instal about 150 lights at the Hob-lane shed, Brierfield, near Burnley, for Mr. J. S. Veevers. The shed is not being lighted, but the remainder of the mill. The dynamos for the mills have been made by Messrs. Rosling and Matthews, of Bradford.

Fareham.—A special meeting of the Local Board has been held to discuss the agreement between the Board and the electric light company as to the purchase of the company's undertaking. The Clerk

Digitized by Google

informed the Board that he had received a letter from the electric light company accepting the amended terms for the purchase of the works by valuation instead of for £5,000. He had had the agreement prepared accordingly. It set forth that the purchase was to be by valuation as a going concern, an arbitrator being appointed by each side, and should they not agree as to the price, the final decision to be given by an umpire. It was also stipulated that the company should lay down the mains in the greater part of West-street, underground, these mains being armoured cables. For this the Board would pay £1,000, receiving back any surplus there might be over the actual cost of the work, but not having to pay the company any additional cost over the £1,000. After some discussion it was agreed to fix the seal of the Board to the contract. The appointment of the Board's arbitrators was next considered. It was eventually agreed to appoint Dr. Fleming at a fee of 50 guineas, and failing him, Mr. Arthur Preece at a fee of 25 guineas.

Search-Light at Hawarden Castle.—A three days' fête was held last week in the grounds of Hawarden Castle, and was opened by the Right Hon. W. E. Gladstone, M.P. In spite of the somewhat unsettled weather it was a great success, and there will be a considerable sum to hand over to the credit of Hawarden Institute, etc., for the benefit of which it was held. Each evening the greatest interest and amusement was created by the powerful search-light, worked from the castle roof, which lighted up the grounds in a most picturesque manner, and caused roars of laughter when its searching rays disclosed two ardent lovers who little thought that their quiet nook was to be changed into a *tableau vivant*. In addition to these personal attentions, the light varied its extraordinary powers by throwing congratulations on to the clouds and belts of trees, etc. On two evenings Mr. Herbert Gladstone, M.P., personally inspected the apparatus and spent a considerable time on the castle roof watching its working, and expressed great astonishment to see "God Bless Victoria R I.," "Blessings on the Gladstone Family," as well as other words, written clearly on the clouds in brilliantly white letters of immense size He warmly congratulated Captain Ronald Scott, and thanked him on behalf of the committee for having given his services and lent the apparatus for the benefit of the Hawarden Institute.

Islington, N.—A committee of the Islington Vestry has been making enquiries as to the relative cost of gas and electricity, especially with regard to street-lighting. The members report that they have been unable to obtain any definite data from actual experience of the relative cost of lighting public streets by gas and electricity. In nearly every town where the streets are lighted by electricity, the current, the committee state, is supplied by a private company, and the charges made by these companies cannot be taken as representing the cost of street-lighting. With regard to St. Pancras, the committee learned that there the cost of electric lighting in the main streets was not likely to exceed the previous cost of gas. Finally, the committee say they have come to the conclusion that the lighting with arc lamps of the route from The Angel to Finsbury Park—viz., High-street, Upper-street, Holloway-road (as far as The Nag's Head), and thence along Seven Sisters-road, to the park—which is projected as a commencement, would cost little (if any) more than the present cost of gas, particularly if arrangements are made for switching off half the lamps at midnight, or for fixing incandescent lamps to take the place of the whole of the arc lamps after that hour. Moreover, the illumination of the streets would be at least quadrupled, and the light would make the thoroughfares named much more attractive, and thereby tend to promote trade in the neighbourhood.

Sunderland. — The sub-committee on electric lighting has just issued a circular containing terms for the supply of electricity which they propose to recommend to the Highways Committee for adoption. According to the circular the charges for a supply of electricity will be as follows: for lighting, 6d. per Board of Trade unit; for heating, cooking, or driving motors, if supplied through a separate fuse and meter, 3½d. per Board of Trade unit. The annual charges for fuse and meter (which are the property of the Corporation and maintained by them), payable quarterly, will be as follows:

Heating, cooking, and power.

h.p.	h.p.	h.p.	h.p.	h.p.	h.p.	h.p.
1 ...	2½ ...	4 ...	5 ...	6 ..	7 .	8 ... 10

Lights of 8 c.p. or their equivalent.

10 ...	25 ...	40 ...	50 ...	60 ..	70 ...	80 ...	100
lights.	lights.	lights.	lights.	lights.	lights.	lights.	lights.

Fuse and meter.

8s. ... 10s. ... 12s. .. 13s. ... 14s. ... 16s. ... 18s. ... 23s.

Above 10 h.p., or 100 lights, special terms will be quoted for the above apparatus. These charges include all repairs due to fair wear and tear; any damage done by fire or negligence on the part of the consumer will be repaired at his expense. One Board of Trade unit will supply electrical energy to one 8-c.p. incandescent lamp for (approximately) 31 hours. One thousand Board of Trade units will supply a 1-h.p. motor for (approximately) 1,000 hours. The circular then goes on to set forth the advantages of electricity, both for lighting and motive power.

Winchester.—The Public Works and Buildings Committee of the Hants County Council have reported that, in accordance with the request made to them at the last meeting of the Council, they had fully considered the cost which would be incurred by introducing the electric light into the new county buildings. The cost of wires, irrespective of brackets, etc., would be approximately £187, and inasmuch as the placing of those wires in position while the buildings were in progress would cost materially less than their introduction at a later period, they recommended that this should now be done, and that the committee should be instructed to obtain an estimate for the wires. Should it be thought desirable to adopt electric lighting, a further sum of, say, £138, would be required for brackets, pendants, etc. The total cost for fittings in connection with this lighting would thus amount to £325. The cost of gas fittings allowed for in the contract for the new buildings was £230. If an independent system for producing electric light were adopted in the new county buildings, the total cost, inclusive of fittings, was estimated at £800. This additional expenditure would, however, not be necessary if the city of Winchester (which now had the question before it) decided on adopting any such scheme as would enable the county offices to be associated therewith. The recommendation with regard to electric lighting was supported by Mr. Lemon, who stated that the electric light at the Southampton Free Library cost less than gas. Mr. C F. Wilson also thought they should have electric lighting. The recommendation was agreed to.

The Leeds Tramways.—The Tramways Sub-Committee of the Highways Committee of the Leeds Corporation are going to the Isle of Man on the 29th inst. to inspect the electric tramway there. Mr. W. Owston writes to a local paper as follows: "Would it not be a great convenience if the electric trams could be run through from Sheepscar to Briggate? I think this might easily be done without having posts and wires put down if the cars were fitted with small accumulators, which might be charged from time to time. As the distance is only about one mile each way, only small accumulators would be required. If this system could be worked at a reasonable rate, it might be applied in many cases, leaving the ordinary wires and posts in the outskirts of the town. Possibly some of your readers well up in electricity will let us know if electric cars can be worked as stated." Another correspondent, signing himself "Motive Power," writes: "It may not improbably be the ultimate outcome of working tramcars to make each car self-contained, and worked with its own motor from accumulators carried along with it. The tendency of invention makes that way, for men naturally reason it out that it is, on the whole, the best that each vehicle or machine should be independent in itself, and if aught goes wrong with it, removing it does not interfere with the work of others similar to itself. Where cars or machines are worked by some connected system from a fixed station at the centre or terminus, should aught go wrong with the operating system every car or machine may be rendered useless till things are put right. Three weeks ago an account appeared of trials in France of motive-power carriages for common roads. The entries showed an interest and a desire to solve this problem, which is very lukewarm in this country. It would not seem an unwise or costly proceeding for our Corporation to invite offers for the construction of a self-contained electric motor car. The cost of this would be a mere item compared with an entire electric tram system, and a successful car such as Mr. Owston suggests may solve the whole problem of what is the best system for Leeds."

Telephony at Worsley. — The Parochial Committee at a meeting a short time ago received a communication respecting the connection of Walkden with a telephonic system, and a sub-committee was appointed to investigate. Mr. Davies now reported that in company with Mr. W. A. Booth, who had been acting in the matter independently of the Parochial Committee, he waited upon Mr. M'Lean, the representative of the New Telephone Company. The National Company wanted £2 per wire more than the New Company. Mr. M'Lean said they would put a central call office in Walkden, and would lay down a line direct to Manchester without having to connect with Bolton. There would be two wires for each person (whereas the National Company only put down one), and the charge would be £8 per year for places within a mile of the central office, and £10. 10s. for connections within a mile and a half. Government did not allow any company to send messages, but anyone could go to the central office and for the sum of 3d. speak to anyone having a connection; the conversation could be kept up for 10 minutes for this amount, or longer if the wire was not required. The company required a guarantee of £80 for the first year, and so far four names had been given in, and others had said they would secure a connection when the central office was established. The company could have the system completed within two months after the guarantee was given. There was no doubt in the minds of the sub-committee that it would be an advantage to the business people of Walkden, but they did not recommend that the rates should be pledged as a guarantee against any deficiency. He had no doubt that sufficient subscribers could be obtained to constitute the necessary guarantee. For an additional £2 the subscribers could have the advantage of being connected also with any member of the National Telephone system. Mr. Marsh said it was very necessary that subscribers should have this last-mentioned advantage, because so many of the Manchester people had connections with the National Company. He thought every subscriber would pay the additional £2, and that really eight subscribers would then be sufficient to form the guarantee, and of these four had already been secured. No resolution was passed, the committee making no recommendation, being of opinion that the matter could be brought about without any guarantee from the rates.

Yarmouth.—On the advice of their expert, the Electric Light Committee of the Town Council recommended that the charge for electrical energy be fixed at 6d. per Board of Trade unit, equivalent in his opinion to gas at 3s. per 1,000 cubic feet. On this basis it was stated an 8-c.p. lamp would cost rather less than ¼d. per hour, and taking an average of 300 hours per annum, the yearly cost

Digitized by Google

would be 6s. 6d., including incandescent lamp renewals. The cost of installation was put at from 20s. per lamp, and the current could be used for lighting, motive power, cooking, or heating purposes. The surveyor on July 11 reported that the trials with the light on the parade and Regent-road were satisfactory, and was directed to keep these lamps lighted for six weeks from that date from one hour after sunset till 11.30 p m. In response to a request from the Mutual Drift Net Fishing Boat Owners' Protection Society, the committee recommended the Council to fix three additional lamps on temporary posts between the south end of the covered market and the Lower Ferry. The committee appointed Mr. A. W. Ranken clerk of the works at £3. 3s. per week from June 27. Mr. Preece recommended Mr. Ranken very highly, he having qualified by study at King's College, London, by a three years' pupilage under the Electric Supply Company, Wolverhampton, and two years' further service, and by 12 months as second engineer at Bristol. Mr. Ranken will act as engineer-in-charge of the present temporary installation. If desired, the light will be supplied to the free library at a reduction of 33 per cent. Mr. E. A. Durrant objected to the position in which it was proposed to place the electric light lamps at the Fish Wharf, asserting that those positions would be a hindrance to trade, and involve an outlay of £550 with but little advantage. He moved that the paragraph be referred back to committee. Mr. Goate seconded. Mr. Suffling said that the lights were fixed on the recommendation of Mr. Preece and of a meeting of smackowners, who quite understood the requirements at the Fish Wharf. On a division the amendment was lost. Mr. Lee failed to understand the appointment of Mr Ranken. Surely Mr. Preece, getting £750 for his services, might wait till he had handed over the job complete. He therefore moved that the appointment be deferred until the installation was completed. Mr. Stanley seconded. Mr. Clowes could not understand what the position was. Mr. Ranken was to be paid by the Corporation, and yet he was a nominee of their electrical expert, and could have no power over the contractors. Mr. Green said that when the Town Hall was built they had a clerk of the works who was a nominee of the contractor, and got into sad trouble. The Mayor said that Mr. Ranken was appointed because it was necessary that there should be a clerk of the works to watch over the interests of the Corporation. Mr. Williment said that it was asked that they should pay him from June 27. Who employed him? The Surveyor: Mr. Preece sent him down. Mr. F. Palmer said that there had been a gross irregularity, and they ought not to pay him. For Mr. Lee's amendment five voted, and 16 against. Messrs. Crampton and Co.'s tender for an electric light installation at the school of art has been accepted by the Town Council at £57. 18s. 6d.

PROVISIONAL PATENTS, 1894.

AUGUST 13.

15376. **Improvements in holders for globes or shades of electric, gas, or other lamps.** John Whitehead, 36, Temple-street, Birmingham.

15403. **Improvements in automatic alarm devices for use in connection with telephones and microphones.** Chr. Hugo Krützfeldt, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

15414. **Improvements in telephone annunciators and call bells.** Frederick George Warrell, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

AUGUST 14.

15424. **Improvements in electromotors.** David Cook, 30, Lancaster-park, Richmond, Surrey.

15429. **Improvements in conducting and economising electricity.** Joseph Lindley and George Edward Sutcliffe, Britannia Mill, Mirfield, Yorks.

15452. **Improvements in electric arc lamps.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Robert Drysdale, United States.) (Complete specification.)

15455. **Improvements in telegraphic transmitters.** Frank F. Howe, 46, Lincoln's-inn-fields, London. (Complete specification.)

AUGUST 15.

15506. **Improvements relating to voltmeters, which are applicable to ampere-meters.** Frederick Brown, 36, Temple-street, Birmingham. (Complete specification.)

AUGUST 16.

15573. **A new method of utilising running vehicles and machinery for the production and storage of electric force.** James T. Cathcart, Pitcairlie, Newburgh, Fife.

15617. **Improvements in apparatus for registering the number or duration of telephonic conversations.** August Münch, 4, South-street, Finsbury, London.

15632. **Improvements in methods of and apparatus for heating crucibles by means of electricity.** Adam Charles Girard and Ernest Auguste Georges Street, 45, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, 19th February, 1894, being date of application in France.)

AUGUST 17.

15694. **Improvements in or relating to electric arc lamps.** Eugene Henry Maret, 323, High Holborn, London.

15675. **An improved vehicle to be used on ordinary roads and propelled by electricity.** Edmund Seymour Colchester, 18, Endwell-road, Brockley, London.

15698. **Improvements in electric appliances for boiling or heating liquids.** Friedrich Wilhelm Schindler, 433, Strand, London.

15712. **Improvements in what are known as dry voltaic cells or batteries.** Donald Barns Morison, 46, Lincoln's-inn-fields, London.

AUGUST 18.

15770. **Improvements in electric heating apparatus.** John Augustine Kingdon, 54, Beresford-road, Canonbury, London.

15774. **Improvements in electric cables.** Henry Alfred Charles Saunders, 24, Southampton-buildings, Chancery-lane, London. (Robert Greey and Walter John Murphy, ——.)

15782. **Improvements in the manufacture of carbon for electrical and other purposes.** Charles Percy Shrewsbury, Frank Laurence Marshall, John Cooper, and John Laskey Dobell, 57, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1893.

15907. **Insulator for telegraph and telephone wires.** Koster.

17493. **Thermo-electric batteries.** Dion.

17981. **Magneto-electrical igniting apparatus.** Drach.

18019. **Electrical switches.** Tucker.

18530. **Conductors for electric railways.** Siemens Bros. and Co. and Thornton.

18674. **Electrical receiving instruments and relays.** Phonopore Company and Spagnoletti.

21629. **Telegraphy.** Delany.

1894.

1776. **Electric arc lamps.** Walton.

9117. **Electromagnetic tools.** Jensen. (Fonda.)

10393. **Arc lamps.** Claremont.

11219. **Incandescent electric lamps.** Hussey.

12099. **Dynamo-electric machines, etc.** Joel.

12131. **Electric brake for vehicles.** Freedley.

NOTES.

Ship-Lighting.—The latest P. and O. steamer, the "Caledonia," is lighted by electricity.

Generally the Case.—The consumption of gas in Bristol, notwithstanding the use of the electric light, is increasing.

Evening Classes.—The Drighlington School Board are arranging for evening classes in electricity during the coming winter.

Telephony in Germany.—Telephonic communication has been established between Frankfort-on-the-Maine, Bockenheim, Offenbach, and Bruchsal.

Search-Lights as Advertisements.—A Birmingham resident waxes highly indignant in the columns of a local paper because some tradesman uses a search-light for advertising purposes.

Electric Clocks for Liverpool.—Complaints having been made as to the inaccuracy of the public clocks in Liverpool, a correspondent suggests the introduction of a system of electric clocks.

Electric Welding.—At the annual meeting of the Institute of British Carriage Builders, which has been held this week at Birmingham, Mr. E. Manville read a paper on the application of electric welding to carriage building.

Book Received.—We have received from Messrs. Whittaker and Co. a copy of "An Introduction to the Differential and Integral Calculus," for the use of students reading without the aid of a tutor. The author is Mr. Matthew Wyatt, F.R.G.S., F.I.I.

Modern Lighthouse Service.—A paper on this subject, accompanied by illustrations, is published in *Cassier's Magazine* for August, from the pen of Mr. Edward P. Adams, C.E. The paper will be followed by others dealing with this branch of work.

Lightning the Lifter.—"A Man Carried Over a Hedge by Lightning" is the sub-heading of a paragraph in a Welsh paper. As some of our contemporaries are fond of filling up their columns with details of such occurrences, we leave this matter for their consideration.

The "Electra."—The steamer "Electra," belonging to the Eastern Telegraph Company, arrived in the Bosphorus on Tuesday morning from the Black Sea with a distinguished company, consisting of Lord Wolseley, the American Ambassador in London, Sir Evelyn Wood, Sir John Pender, and others.

London County Scholarships.—The London County Council have issued the report of their Technical Education Board on the examination for intermediate county scholarships held in June last. The examiner stated that in electricity and magnetism "very few showed any practical knowledge of laboratory work."

Visits to Works.—The members of the Manchester District Institution of Gas Engineers inspected on Saturday the gasworks and electric light station at Huddersfield. The members of the Junior Engineering Society on Friday last visited the Cardiff electric lighting works, Mr. Fletcher, the electrical engineer, explaining the various features.

Large Overhead Traveller.—It would be interesting to learn whether there is an overhead electric traveller in existence larger than that in operation at the Seraing works of Messrs. John Cockerill and Co., in Belgium. This traveller, which was inspected by the members of the Iron and Steel Institute last week, has a capacity of 60 tons, and is used, among other purposes, for the lifting of huge ingots for pressure under a hydraulic forging press. Perhaps some of our readers may be able to give us information on the subject.

Electric Lighting in Natal.—The Durban Town Council have approved of the borough engineer's recommendation that the best advice in England should be obtained on a general scheme for lighting the whole borough by electricity. It has been decided to take steps at once to carry out the details, and to employ such assistance as may be needed. The Seaman's Institute have applied to the Natal Harbour Board for their terms for supplying the institute with the electric light. The application has been referred to the Government.

Glasgow and West of Scotland Technical College.—This college grants diplomas in the following departments of engineering and other branches of applied and general sciences: civil engineering, mechanical engineering, naval architecture, electrical engineering, architecture, chemical engineering, metallurgy, mining engineering, agriculture, chemistry, and mathematics and physics. The session 1894-95 commences on Monday, October 1. Mr. John Young, B.Sc., the secretary, will supply particulars as to fees, scholarships, etc.

Ealing Exhibition.—Great efforts are being made to obtain a good exhibition at the opening of the central station. Not only are exhibitors invited, but special attention is being paid to get visitors to the exhibition. Thus arrangements have been made to obtain lectures during the time of the exhibition, and Sir F. Bramwell, F.R.S., has promised to deliver a lecture on the opening day. Among others who will lecture are Mr. E. Graham Harris and Mr. C. W. Lynd. There will also be a phonographic night and several musical evenings. The promises of support already received go far to ensure a great success.

Pacific Cable Question.—The *Post*, discussing the Ottawa conference, says the colonies will do well to keep the decision of the late conference before the Home Government, and not let the matter remain in abeyance, as was done with regard to the resolution passed at the colonial conference in 1887, when it will be remembered that the same conclusion about a survey was come to, and yet during the seven years that have elapsed since that time no steps whatever have been taken in the matter. Doubtless a survey would in any event be a wise preliminary before laying a cable in unknown waters, but at the same time it seems from the expert evidence given at Ottawa that with the modern methods of cable work a survey is not altogether indispensable. But that is a matter, the *Post* concludes, for the colonies to decide, and as they have decided in the affirmative it is not for us to find fault with the increased delay.

Obituary.—The death took place on Tuesday of the Earl of Albemarle—the Right Hon. William Coutts Keppel. The deceased, who was born in 1832, took a great interest in the applications of electricity, and was chairman of the late General Electric Power and Traction Company, Limited. It will be remembered that in 1890, when Lord Bury, he wrote to the *Times* a letter asking for suggestions for a verb to express progression by electric power, which called forth a large number of answers. "To motor," was the verb which was selected as the most suitable, but neither that nor any other of the words proposed seem to have been adopted.—A long obituary notice appears in a German contemporary on Carl Grawinkel, who recently passed away. The deceased was a well-known telephone and telegraph engineer, and was the author of several works dealing with these branches of industry.

Lighting in Calcutta.—It passes understanding, *Indian Engineering* remarks, how the metropolis of the East—the greatest of Asiatic cities—the centre of the civilisation introduced from the West—carries on month after month and year after year without the aid of electricity. To think of lamps that rarely require trimming and that are wind and stormproof, of punkahs that do not necessitate the employment of a dirty, lazy class of creature, and do not swing with such irregularity as to render them a serious risk to health, besides numerous other uses to which electrical power might be put, form a dream to Indians, but to the scientific and professional men of Europe and America these are now every-day achievements, and to them the remark would occur: "Well, if Calcutta has not these modern means and necessary appliances, it is entirely its own fault, and someone or other requires a little life shaken into him."

Platinum.—The Ural platinum deposits in Russia are said to be the only ones in the world, as this metal is worked nowhere else, and is known simply as a mineral finely disseminated in certain rocks. Platinum occurs in the Ural Government of Perm, where it is found on various private properties and State lands. In the district of Goroblagodat there are 70 allotments for the exploitation of platinum under different private individuals. At present all the platinum extracted in the Urals is forwarded in the crude state to St. Petersburg, whence it is sent abroad. Although there are two laboratories in the Russian capital for refining platinum ore, the greater quantity is sent abroad in the crude state. The largest quantity of platinum is now extracted at the deposits of Nizhni-Tagilsk, belonging to Prince Demidoff San Donato, and at the Krestovosdvigensk deposits of Count Schouvaloff. In 1890 there were 6,000 workmen employed in the exploitation of platinum.

Employment of Electricity to Follow the Phases of Certain Chemical Reactions.—Mr. J. Garnier, in the *Compt. Rend.*, observes that a mixture of nickel oxide and wood charcoal was placed in an earthenware tube, closed by two plugs of soft steel, by which the mixture was compressed. The two steel plugs were placed in an electric circuit, and the earthen tube, supported horizontally, was heated in a small reverberatory furnace. The resistance of the powder in the tube was at first extremely high, but gradually became less and less, until it became almost nil. It then increased again, finally becoming very high. The decrease of resistance corresponds with the gradual reduction of the oxide, the reduction being complete at the moment when the resistance was almost nil; as the nickel became carburetted, however, the resistance increased. In a similar experiment, with a mixture of copper, iron, and nickel oxides and wood charcoal, the successive phases of reduction were indicated by the variations in the resistance. In the same manner, the process of refining might be followed, and the method has the advantage that the readings of the ammeters and voltmeters can be made at a point removed from the position of the furnace, etc.

Three-Wire System in Italy.—A central electric light station has recently been set in operation at Jesi, in Italy. The station is situated in the lower part of the town, where a turbine-house has been erected close to the Canal Pallavicino. The available water supply amounts to 4,300 litres per second, the useful fall being 16½ft. There are installed two 100-h.p. turbines, constructed by Messrs. Calzoni, of Bologna, on the American reaction type, and provision has been made for the laying down of a third turbine. The turbines drive by means of bevel gear two horizontal shafts, which, by means of Raffard flexible couplings, actuate two dynamos at 360 revolutions a minute. Messrs. Siemens and Halske have supplied the whole of the electrical plant. At present two dynamos giving 510 amperes at 130 volts are installed, the current being distributed on the three-wire system. A separate circuit is provided for the requirements of the town, a second for the arc lamps, and a third for private consumers. The town is supplied with 300 16-c.p. lamps, which are alight throughout the night, and 18 nine-ampere arc lamps, eight of which are switched out at midnight. Messrs. Moleschott, of Rome, the representatives of Messrs. Siemens and Halske, have carried out the whole of the electrical and hydraulic portions of the work.

Two-Phase System in Hungary.—The central electric light station in operation in Budapest is the property of the Austrian General Gas Company. It has been built in the outskirts of the town on a site leaving ample room for future extensions. The generators comprise three two-phase alternators each of 400 h.p., and two smaller alternators of 70 kilowatts. From the generating station the current is transmitted to a sub-station, where it is converted into direct current. The transmission along the line is effected by a system of diphase alternating current, produced by an alternator having a "continuous" winding. This winding is arranged in four sections, each of which is connected to a ring. The current collected on these rings is led by four wires to the sub-station, where it energises alternating synchronous motors constructed in a similar manner to the generators. These motors drive direct-current dynamos, which feed into the mains and also charge accumulators. Each alternator at the generating station is provided with an exciter; common exciting bars form a kind of reserve, these being fed from the sub-station by means of a separate feeder.

Personal.—"There is something of historic interest," says the *World*, "in the nomination by Lord Kelvin of Mr. Charles Bright, C.E., to fellowship of the Royal Society of Edinburgh, for which the latter is now a selected candidate. Lord Kelvin and the late Sir Charles Bright were old shipmates, as the electrician and the engineer respectively of the old Atlantic cable, for the successful laying of which Sir Charles received knighthood at the unprecedentedly early age of 26. His eldest son, Lord Kelvin's nominee at Edinburgh, seems to be gradually coming to the front on the same lines as his distinguished father, one of whose well-remembered feats was laying down, when only 18 years old, the telegraph lines under the streets of Manchester in a single night, to avoid disturbance to the traffic, thus for the first time putting Liverpool and Manchester into telegraphic communication with London. Mr. Charles Bright's recently published volume on "Subterranean Telegraph Cables" marks him as a close scientific observer with keen practical instincts, and embraces a wider range than its title implies. There have been books before giving the history of submarine cable-laying expeditions, but never one furnishing the precise course of events from start to finish, and showing with minute detail how the inevitable difficulties in a treacherous climate, that of the West Coast of Africa, where Mr. Bright was in charge of the enterprise on behalf of the Silvertown Company, are grappled with and overcome."

Electric Lighting in Germany.—The local authorities have authorised the laying down of electric light mains in various parts of Berlin by the Berliner Elektricitätswerke. The machinery and boiler house in connection with the central electric lighting station at Frankfort-on-the-Maine is completed structurally, and good progress is being made with the large chimney. Three of the six boilers required are in place, and one of the three

Digitized by Google

750-h.p. tandem steam-engines has been erected. The boilers and engines are made by Mr. G. Kuhn, of Stuttgart-Berg. The dynamos are lying ready at the works of Messrs. Brown, Boveri, and Co. A concession has been given by the municipal authorities of Leutkirch to Mr. Schöllhorn, of Unterzeil, for a central electric lighting station. The concessionaire is to pay the town £20 a year and 10 per cent. of the net profits, and provision is made for the taking over of the works by the local authority under certain conditions if they desire to do so. The local authorities at Schaffhausen will themselves carry out the central station, and tenders are to be invited. The Arms Factory at Dantzic is to be lighted electrically. A central station is projected for Landstuhl. The new central station which has been built at Haardt by Messrs. Schuckert and Co., of Nuremberg, has been opened. The plant comprises two Lancashire boilers, two steam-engines each of 60 h.p., two Schuckert dynamos, and two batteries of accumulators.

The London-Ostend Telephone.—In our last issue we recorded the intelligence issued by Dalziel's Agency with respect to the proposed establishment of telephonic communication between London and Brussels, *vid* Ostend. The London correspondent of the *Liverpool Courier* now writes as follows: "The report of the establishment of direct submarine telephone communication between London and Ostend being impending has already been contradicted, but enquiries which I have made point to the conclusion that the report was much more 'previous' than was at first supposed. The fact is that as yet the project exists merely as an idea in the minds of enthusiastic electricians and enterprising men of business. The writer of the original report spoke as if the establishment of such a telephone would be a comparatively easy matter; as if, indeed, it would only be necessary to give the order and the thing would be done. But the fact is that telephone cables have to be made with exceptional care. They take a long time to construct, and are very expensive. Happily, this country is still in the proud position of having, by the admission of all electricians, the two finest telephone cables in the world. These are the cables between Dover and Calais for the communication between London and Paris, and the cable between Belfast and Glasgow. Both are of English manufacture and laying down. They are in daily increasing demand. Business on the cable between Belfast and Glasgow was rather slow at first, and it looked as if the enterprise would be a financial failure, but with the adoption of a reduced tariff of charges business has gone up rapidly."

Dielectric Constants and Chemical Equilibrium. Mr. W. Nernst, in the *Zeit. Physikal. Chem.*, states that as the energy of an electrically-charged system is lowered when placed in a medium of higher dielectric capacity, there is hence an attractive force on electric points towards the medium with the higher capacity. From this he deduces, by considering the ions as electrically-charged points, that the greater the dielectric constant, κ, of a medium, the greater will be the electric dissociation of a dissolved substance. Data for verification are few, but the known facts support this view, thus:

	κ	Electric dissociation.
Gases.....	1·0	Not at ordinary temperatures.
Benzene	2·3	Very slight; traces.
Alcohol.....	25 0	Distinct.
Water	80·0	Very strong.

Experiments also on the dissociation of hydrogen chloride gave: benzene, xylene, and hexane, very slight; ether, slightly stronger; then isobutylic alcohol, ethylic alcohol, and methylic alcohol, the order being the same as that of the dielectric capacity. Many organic acids contain molecular complexes, which decompose first into simple molecules and then into ions. The decomposition would also probably follow this law. This action is observable in the following order, according to the measurements of Eijkman and Beckmann: hydro-carbons ($\kappa = 2·2—2·4$); carbon bisulphide ($\kappa = 2·6$); chloroform (κ ?); ether ($\kappa = 4·4$); ethereal salts ($\kappa = 6—9$); alcohols ($\kappa = 16—33$); acids (κ ?); and water ($\kappa = 80$). A short indication is also given of a method for the simple and accurate determination of the constants.

Lighting of Tramcars.—A system of lighting tramcars by electricity has been devised by Mr. W. M. Miner, the electrical engineer of the American Manufacturing and Engineering Company, New York, and a demonstration of it was recently given as installed in a car in Hoboken, N.J. The visitors were conveyed in the car, and in running over the line the trolley circuit was frequently broken in order to show the value of this system in always keeping the car illuminated whether the trolley wheel is on or off. The system consists in the use of a small storage battery of six Donaldson-Macrae storage cells, which are used to light a duplicate set of lamps should the trolley come off, or the motor current gives out or be interrupted in any way, the battery being switched on automatically when the motor circuit is broken. A trolley current is passed through an electromagnet, which completes a circuit through incandescent lamps connected in series in the usual manner. The same current also passes through the storage battery, keeping it charged. If the trolley comes off, or the current gives out or is interrupted in any way, the armature of the magnet is drawn back against its backstop, closing the supplemental circuit from the storage battery through a switch to the armature of the magnet, backstop and lamps, returning to the storage battery, thereby ensuring light in the car whenever lights are required independent of the action of the trolley. When the main circuit is restored by replacing the trolley or otherwise, the current takes its original course through the main circuit lamps, energising the magnet (drawing its armature away from the backstop), storage battery, and ground, recharging the storage battery and lighting the car as before, thus automatically ensuring a constant light in the car under all circumstances.

Champagne, Good and Pure.—Our French contemporary, the *Bulletin International de l'Electricité*, frequently endeavours to discover new ideas, the latest of which is a method for hermetically sealing champagne and other bottles. In order that the lucidity of the system may not be destroyed, we quote the following from our contemporary's issue of August 27: "Under the title of electric capsuling is designated the operation of surrounding an article with an envelope which is generally metallic. Hitherto, the coating of pills in pharmacy, for instance, has been done by hand, but, judging from some special applications, electric capsuling may be called upon to dethrone the old method. The electrical system has at first been applied to the corks of champagne and beer bottles. It would appear that the cork and the metallic capsule alone of a champagne bottle cost 3d.—being 2d. for the cork and 1d. for the capsule. The neck of the bottle and the cork are covered with a conducting layer; the cork is then driven in the bottle, and the whole placed in a copper, nickel, or aluminium bath. The metallic deposit closes the pores of the cork, and effects a perfect connection between the cork and the neck of the bottle. It seems that the producers of champagne lose 5 per cent. of the wine by the old method through defective corking, which loss can be avoided by the adoption of the new system. Beer bottles also require to be hermeti-

Digitized by Google

cally closed, and this result can be obtained by covering the neck of the bottle with a ring of pure cellulose cardboard (*carton de cellulose*), upon which a metallic deposit is made. Finally, the latest success of the new method is an application to the preservation of rolls of butter, which are covered with plumbago and a film of copper electrically deposited."

Association of Chambers of Commerce. — A special meeting of the Association of Chambers of Commerce will be held at Huddersfield in September. The following are among the resolutions on the agenda: "That this association expresses its hearty approval of the resolutions adopted by the inter-colonial congress recently held at Ottawa in favour of inter-Imperial postal and telegraph routes between this country and the colonies and between the colonies themselves respectively without such routes passing through other countries. And this meeting would urge on the Postal and other Governmental Departments the importance of aiding as far as possible the proposals of the congress, and that memorials be sent to the Prime Minister, the Chancellor of the Exchequer, and the Postmaster-General." "That in the opinion of this association it is unfair to the public that the telegraphic department of the Post Office should for financial purposes be treated as a separate establishment, thereby causing unwarrantable delay in carrying out urgent and much needed reforms. That inasmuch as the postal establishment and its various departments are in their entirety a financial success, the time has arrived when the address of not exceeding four words should be allowed free of charge in all telegrams, and that telegraphic communication should be extended to rural districts where practicable. That a deputation wait upon the Postmaster-General to urge upon him the desirability of adopting this suggestion"; and "That this association reaffirms the desirability of the law relating to the rating of machinery being settled in accordance with the principles in the Bill which was introduced into Parliament, and that her Majesty's Government be requested to give facilities during the next session for the passing of an Act to settle the law upon the subject."

The Ferranti Effect.—Before the Electrotechnical Institute of the Technical High School in Vienna, Mr. J. Sahulka recently read a paper explanatory of the Ferranti effect. The paper, which is reproduced in the *Zeitschrift für Elektrotechnik* of August 15, deals with the question from a mathematical point of view. The author stated that the Ferranti effect comprises a series of phenomena which arise if the secondary circuit of a transformer, the primary circuit of which is connected to an alternating-current machine, is closed through a condenser. The most remarkable of these phenomena is this: that the ratio of transformation of the converter increases. At the same time, the primary difference of potential also becomes greater and the primary current weaker. The condenser, the author observed, must not have too great capacity, as very large condensers in alternate-current working have only a small apparent resistance, and a condenser of infinitely great capacity might have the same effect as if the secondary circuit was short-circuited through a piece of wire. The ratio of transformation through the insertion of the condenser in the secondary circuit can be greater than the relation of the number of windings of the transformer. According to Mr. Sahulka, a correct explanation of this phenomenon has not hitherto been given. The cause of the effect, he states, lies in the so-called distribution of the magnetic lines of force in the transformer. This assertion is shown theoretically, and was confirmed by experiment. If all the magnetic lines of force produced by the primary circuit were passed through the whole of the windings of the secondary circuit and reversed, the Ferranti phenomenon would not arise. After having gone into the question mathematically, the author describes the experiments made which led him to the above conclusion.

Electricity in Nishni-Novgorod.—At the world-famed Nishni-Novgorod Fair, according to a correspondent of the *Elektrotechnische Zeitschrift*, considerable business is done in electric bells, batteries, wire, indicators, and lightning conductors, mainly of German and Austrian manufacture. Moreover, according to the police regulations in the district in which the fair takes place, the use of any light save the electric light is prohibited. Thus arc and incandescent lamp lighting are to be found in the meanest booths as well as in the governmental palace and in the theatre. The central station for the electric light is situated in a one-storey building at the side of a tributary of the River Oka. The boilers, steam-engines, and dynamos are in the basement, and the regulating and measuring instruments on the ground floor. The whole might serve as an electrical exhibition, for apart from the boilers and engines, which have been made by Messrs. Dobrowich and Nabgoltz, the rest of the appliances show samples from the works of Messrs. Ganz and Co., Schuckert, the Allgemeine Elektricitäts-Gesellschaft, and many other German and Austrian firms. The dynamos work at 230 volts, and 30 volts is lost by the time the periphery of the district is reached; on account of which two 100-volt incandescent lamps of 10, 16, 25, or 32 candle-power are always arranged in series. The arc lamps are supplied from a special dynamo. Overhead conductors are employed. The leading spirit of electricity at Nishni-Novgorod is Mr. Rjumin, a former naval officer, who is proud of the 8,000 incandescent lamps and 150 arc lamps which now constitute the lighting of the fair. The manager of the central station is Prof. Popoff. It is proposed to erect a new large central station to be ready for the fair of 1896.

Use of Rectified Current.—It will be remembered that in connection with the utilisation of Niagara Falls, the Cataract Construction Company have adopted the plan of generating current primarily at 2,000 volts, alternating, at 25 cycles per minute, on the two-phase system. Where the distance to which electric power is to be transmitted is beyond the limits of Niagara Falls this potential is raised by step-up transformers to the desired E.M.F., but for Niagara and vicinity the 2,000 volts delivered directly from the machine will be furnished to consumers, at whose premises it will be transformed to any potential and character desired. The *Electrical Engineer* of New York states that among those who have already arranged to transfer their works to Niagara is the Pittsburgh Reduction Company, the well-known manufacturers of aluminum. This company has contracted for 1,200 kilowatts of electrical energy to be delivered in the form of continuous current, which they require for the reduction of the aluminium. The contracts for the electrical apparatus and the fittings to furnish 7,000 amperes at 160 volts were awarded to the General Electric Company early in the year, and a recent visit to the works at Schenectady show it to be rapidly nearing completion. In order to carry out the conversion of the primary alternating current into the continuous current, rotary transformers in connection with stationary or "static" transformers, as they are called, to distinguish them from the rotary, have been adopted, the system of conversion being as follows: Starting with the 2,000-volt alternating current at the main generating station, the current is led to the works of the Pittsburgh Reduction Company, a

Digitized by Google

distance of about 2,500ft. Here it is led into the static transformers and is reduced to 115 volts alternating. This current is then led to the rotary transformers, which convert it into continuous current at 160 volts, at which pressure it will be used.

Purification of Sugar.—Since the exposure some four or five years ago of the American "electric sugar frauds," which, it will be remembered, deceived some of the English papers, the subject has been practically tabooed. Occasional paragraphs have cropped up in different directions, but nobody seems to know much about the matter. A French contemporary has, however, now returned to the charge. It is, of course, understood that the methods of extracting sugar from sugar juice, which is obtained from the sugar-cane or the beetroot, are practically based upon the treatment of the juices so as to eliminate mineral or organic impurities contained in them. The contemporary in question, *Les Annales Industrielles*, deals with the electrolytic purification of sugar juices mainly from a historical point of view. It would appear from this article that the only place where such a system has been tried practically is at the Hoym Sugar Works, in Anhalt, Germany. We heard of experiments at these works some time ago, but our contemporary declares that the preliminary tests were considered to be so conclusive as to lead to the installation of complete plant, which was used with complete satisfaction during the last campaign. The plant comprises two vats, which contain electrodes of zinc, aluminium, or lead formed of plates of about one metre square, with a thickness varying from 3mm to 5mm., numbering from seven, 10 to 12, and having an active surface of from 12 to 25 square metres. These electrodes are fixed to wooden bars arranged on the boxes, the even number of plates forming the anodes, and the uneven the cathodes. The current is furnished by a small dynamo, which, for a factory working 200 tons of beetroot, can be of about 1 h.p. The juices, heated to 65deg. or 75deg. F., are brought to one of the vats for electrolysis, the other vat being empty or in process of being filled. The current is then switched on and the reaction immediately commences; froth is produced with the freeing of the gases, and is removed by a "diffuser." Certain organic matters are decomposed and give rise to flaky or granulous substances, which are formed in the juice. The operation proceeds for about eight minutes; then the second vat is dealt with and the electrolysed juice is conveyed to the filters, after which it is treated in the ordinary manner.

Electrical Communication with Lighthouses.—The members of the Royal Commission sat on Tuesday in Liverpool, and received evidence as to the present means of communication between the different lighthouses and lightships in and around Liverpool Bay and the shore, and also as to the best means of supplying the present deficiencies. The Earl of Mount Edgcumbe presided, and the other members of the Commission were Sir Edward Birkbeck, Admiral Sir F. Leopold M'Clintock, Admiral Sir George Nares, Hon. H. Mulholland, M.P., Mr. R. Munro Ferguson, M.P., Mr. J. C. Lamb, Mr. W. H. Preece, Mr. J. A. Kemp, and Mr. Ernest Moggridge (secretary). Mr. Harold Bateson, local hon. secretary to the Lifeboat Institution, and the coxswain of the New Brighton lifeboat were examined, and laid before the Commission a scheme for the improvement of the communications. The former stated that it was of great importance that either the Formby Lightship or the Crosby Lightship, or both, should be connected with the shore by means of a telephone, and that that connection should be extended to every lifeboat station and every lighthouse in Liverpool Bay. The coastguards, it was remarked, were the only look-out during the whole of the day, and they in many instances were long distances, sometimes five or six miles, from the nearest telegraph or telephone station. That inaccessibility practically rendered it difficult to summon the assistance of the lifeboat to a vessel in distress within anything like reasonable time. To meet that difficulty his proposition was that a circle of telephonic service was necessary, and that being so he suggested that a connection be established between the Crosby Lightship, the Formby Lightship, and the Formby Lifeboat-house (for the lifeboat crew), thence to Waterloo Coastguard, the Northwall Lighthouse, the Liverpool Landing-stage, the New Brighton Pier, the New Brighton Lighthouse, the New Brighton Coastguard, Bidston Observatory, Hoylake Lighthouse, Hoylake Coastguard, Hilbre Signal Station, Voel Nant Signal Station, and Point of Ayr Lifeboat-house. Then he suggested a subsidiary telegraphic service from Fromby and Crosby to the General Post Office in Liverpool, and through that to New Brighton and Bidston. The Lord Mayor entertained the Commissioners to lunch at the Town Hall; afterwards they visited the Crosby Lighthouse, and on Wednesday they visited the lightships and other stations.

Lightning Flash in a Central Station. — In a recent issue of a French contemporary, M. P. Robert drew attention to a case of this nature. It appears from an abstract published in the *Journal* of the Institution of Electrical Engineers that the central station was struck by lightning during a storm which took place over Paris on April 26 last. The station in question is situated in one of the suburbs of Paris, and transmits power at high tension by means of overhead lines to other stations in Paris itself. This high-tension current works motors driving low-tension dynamos. During the storm, the station was struck, and one of the units broke down in a few seconds. The machine in question was a Marcel Deprez motor of 100 h.p., working two Edison dynamos coupled to each end of the spindle by Raffard couplings. All the electromotors in the station were insulated from earth. The foundation bolts were cemented into the foundation, and were insulated from the bed-plates of the motors by means of ebonite sleeves. The bed-plates themselves were insulated from earth by means of fibre and paraffined oak. The insulation resistance of the whole machine to earth was generally found to be from five to six megohms. Between the armature winding and the frame of the machine the insulation resistance was double these values. The high-tension overhead line, eight miles long, had an insulation of seven to eight megohms to earth. The lightning flash struck the armature of the motor, and appeared to come from the roof of the station. The discharge passed through the shaft of the motor to one of the Edison dynamos, and thence to the switchboard, where a bright flash took place, followed by a loud detonation, and finally found its way to earth through the low-tension network. On the high-tension line all fuses and lightning arresters remained intact, although one of the machines at the generating station was damaged at the same instant. The insulating materials of the motor armature which was struck were completely carbonised, and some of the bars were fused to the gunmetal spiders supporting the discs. On removing the bearings to get the armatures out, it was noticed that at two points on the shaft some of the gunmetal from the bearing had fused on to the shaft. The air-gaps had been the seat of a violent discharge, and traces of copper were found on the polar faces of the magnets. It is therefore very essential that every precaution should be taken, and that the station itself should be protected from lightning as well as the line, or otherwise the consequences may prove most fatal.

MR. R. A. CHATTOCK,

ELECTRICAL ENGINEER TO THE HAMPSTEAD VESTRY.

In presenting the portrait of Mr. Richard Alexander Chattock, A.M.I.E.E., we have to compliment him on his recent appointment as chief electrical engineer to the Vestry of St. John, Hampstead. The subject of our sketch, who was born in 1865 at Solihull, Warwickshire, was educated at University College School, London, from which he passed in 1881 into the college. He remained there until 1884, going through the full engineering course under Prof. Kennedy, and obtained the senior Gilchrist engineering scholarship. The following year (1884-1885) he devoted his attention to the study of physics and electricity in the college laboratory. In 1886 Mr. Chattock passed the matriculation examination of the London University in the first division, and entered the marine and general engineering shops of Messrs. John Stewart and Son, at Blackwall, London, remaining there until 1889, and serving an apprenticeship as a mechanical engineer. From 1889 to 1892 he acted as assistant engineer to the Metropolitan Electric Supply Company at their several stations in Whitehall, Manchester-square, and Sardinia-street; and in the latter 1892, on the erection of the company's new station in Amberley-road, Paddington, he became superintendent engineer at that station, a position which he

has held down to his appointment to the Hampstead Vestry. In January, 1890, Mr. Chattock was admitted as an associate member of the Institution of Electrical Engineers. The Vestry of St. John, Hampstead, as will be remembered, are putting down plant for public and private lighting, with a view to eventually illuminating the whole of the parish by electricity, and the services of the newly appointed chief engineer are required in the organisation and superintendence of the station. We tender our best wishes for the success of the station under Mr. Chattock's management.

THE USE OF ACCUMULATORS WITH MOTORS.

M. G. Darrieus discusses in *L'Electricien* some of the chief points connected with the simultaneous employment of accumulators and electric motors on a circuit, and the following paragraphs contain the substance of his remarks, which are elementary but well arranged.

At the outset he disclaims any effort to analyse from an economical standpoint the use of accumulators for launches or traction work: this he leaves to hard experience, which can alone, through the logic of facts, give satisfactory conclusions. The chief difficulty which presents itself as a rule in applications of this kind is that of suitably connecting the motor with the source of energy so as to vary the speed of motor at will: but an immediate solution suggests itself at once. By varying the difference of potential at the motor terminals, the speed (which is a function of the potential difference) may also be varied. Quite a number of different methods may be employed to effect this, but, of course, the result must be the same whatever method be adopted. According to one such mode, a variable resistance is switched in between the source of energy and

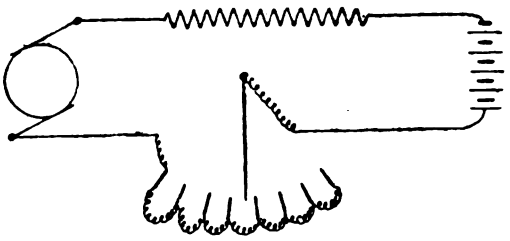

FIG. 1.

the motor in the usual fashion, as is represented in Figs. 1 and 2; in the latter instance, the resistance frame is inserted in the armature circuit, otherwise the variation in voltage produced by moving the resistance switch would vary the motor field, and act upon the speed in a sense opposite to that due to potential difference.

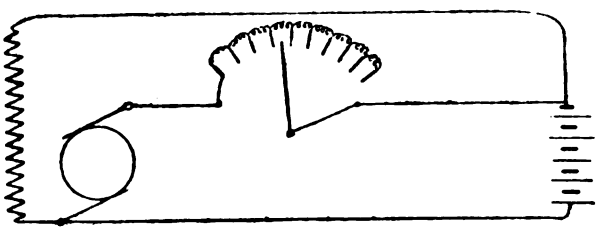

FIG. 2.

This method is only suitable when the speed variations required are few and of very short duration, outside a normal speed corresponding to switching out all the resistance, and it becomes, of course, impossible to use it with an extended scale of speeds. Moreover, it is hardly necessary to remark that this method is very wasteful, since the energy corresponding to the heat developed in the resistance is wholly dissipated without useful effect, and may form a very large fraction of the energy available.

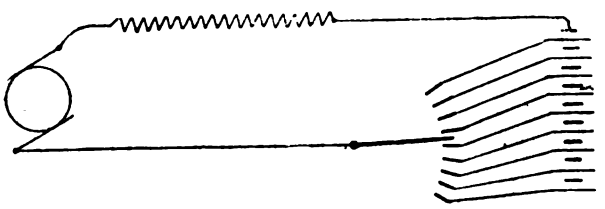

FIG. 3.

A second method of varying the potential difference consists of altering the number of accumulator cells in use. One motor terminal is connected permanently to one battery pole, and the other terminal to an appliance which throws into circuit any desired number of cells. Fig. 3

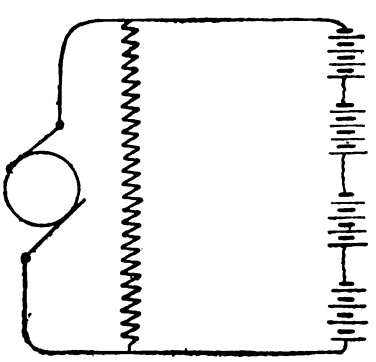

FIG. 4.

shows this device, the potential difference of current supplied to the motor being varied by a movable contact bar and contact plates, each connected to one of a series of accumulator cells. This method, however, has the serious

Digitized by Google

disadvantage of causing an unequal discharge in the cells, with consequent difficulty in recharging and maintaining them, so that a further step in developing a satisfactory and economical plan was taken when the accumulator cells themselves were first divided into a number of equal groups, these being coupled in series or parallel, or combinations of both. The cells are, in this method, each drawn upon to the same extent, and the difficulties of charging and maintenance therefore met more easily.

The variation in arrangement of these battery groups is usually effected by an appliance comprising a series of isolated contacts mounted on a rotating cylinder with brushes (joined up to the battery terminals) pressing on them.

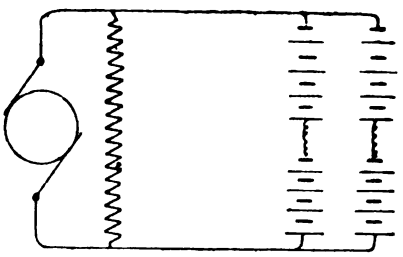

FIG. 5.

Figs. 4, 5, and 6 show a number of combinations possible on this system with four groups of battery cells, the potential differences given being respectively 200, 100, and 50 volts, with corresponding variations in motor speed. It must not, however, be forgotten that, whatever type is adopted for the winding on the motor, variations in the magnetic field produced by different voltages of the current supplied will have an opposite effect on the motor speed to that due to the change in voltage. The waste of energy on a rheostat or set of resistances, however, is avoided.

The chief objection to such a method is that the coupling up of batteries in parallel cannot be relied upon to give satisfactory results, for when we connect accumulator cells by poles of the same denomination, there is a necessary waste of energy due to the fact that the battery plates will never give identically the same E.M.F.'s, although they are to all appearance identical, and have been charged in similar fashion. This fact is readily noticed when a number of cells are charged in series, and then disconnected for separate testing: differences in molecular constitution of the plates—*i.e.*, their want of homogeneity—bad contacts, variations in density of the electrolyte, etc., all have an important effect upon the resultant discharge. The cells of slightly higher voltage discharge into those of lower voltage, the net potential difference being that due to the algebraic sum of the separate voltages.

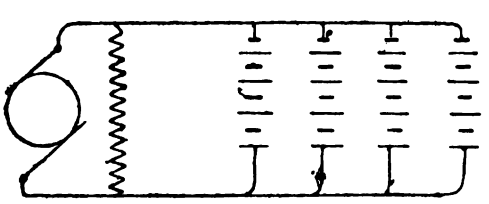

FIG. 6.

Take, for instance, a set of accumulator plates which so far as possible are identical in formation, shape, etc., physically and chemically, and let a battery of 10 cells be made up from these, and be charged in series. They are then disconnected, and joined up into two groups of five cells each; the first group contains five cells arranged, say, in series; the second, five cells in parallel. The two groups are then discharged through external resistances chosen in such a way that the density of current discharge per unit of plate surface is the same in both cases, say, for instance, ·5 ampere per square decimetre.

We ought theoretically to obtain at the battery terminals the same energy in watts, $5 E \times C$ in the first case, and $E \times 5 C$ in the second; but practically this is not the case, and the following table gives the results of tests upon 10 cells, each containing the same weight of plates.

DISCHARGED IN PARALLEL.

The series of discharges in parallel entail a loss of energy of 13 per cent. as compared with the series of discharges in series.

(To be continued.)

THE CORROSION OF IRON PIPES BY THE ACTION OF ELECTRIC RAILWAY CURRENTS.*

BY D. C. JACKSON.

The foundation of this paper is an investigation carried out under my direction by Paul Biefield and Fred. D. Silber, at the University of Wisconsin. I have incorporated the report of their experiments directly into the paper as far as possible. Their work was divided under two heads: first, to determine what chemical action really occurs under the conditions that are met in towns where corrosion of the water and gas pipe systems have occurred through the action of electric railway return currents; second, to examine the action which has actually occurred in various towns, apply the deductions gathered from the results of the first division of the work, and determine the best methods of avoiding difficulty or danger from corrosion.

About two years ago engineers of the West End Street Railway Company of Boston began to connect the reinforcing wire laid between the tracks to the water-pipes, anticipating little or no trouble from so doing. They soon found that the supplementary wire was destroyed in places. They first attributed this to chemical action of the soil, but finally concluded that it was due to electrolytic action. As a remedy, they reversed the polarity of their generators, sending the current out through the rails and back through the overhead trolley wire. This change was followed by disastrous results. The current pumped through the rails took to the water-pipes and lead cable coverings, according to the law of divided circuits, and, leaving these at many points along the line, caused serious corrosions at these places. It was found that lead pipes at some points disappeared inside of six or eight weeks, and galvanised iron and brass pipes deteriorated noticeably in an equal time.

After a conference between representative of the city and the railway company, it was decided to go back to the old way of current distribution. The direction of the current was therefore reversed, and careful tests were made which showed that considerable current flowed along the water-pipes. So great, in fact, was this current that the arc formed at a joint where oakum was used for caulking was sufficient to set fire to the oakum. This loss of pressure on the return circuit was found to be from 25 to 100 volts, or from 5 per cent. to 20 per cent. of the total pressure. As an experiment the water system was connected to the negative pole of the dynamo, and now a new danger was found in the difference of potential between the gas and water pipes, causing a marked electrolytic effect on the former. It was then proposed to connect the gas and water pipes together in all parts of the city in order to arrest

* Paper read before the Western Society of Engineers, July 14.

Digitized by Google

the action, and this was done with fair results. The expense to the city and the company was great, and the final solution of the difficulty was far from satisfactory to either party.

The report of the Board of Commissioners of Electric Subways of Brooklyn for 1892 briefly referred to the same trouble as of uncertain character and extent. Since then the problem has become very serious in Brooklyn on account of the growth of the electric railways in that city, and the same report for 1893 calls attention to the fact that discoveries of corrosion have been numerous enough to justify the belief that all kinds of buried pipes are being eaten away in many places. As an example, may be cited the fact that a certain iron service pipe buried at a depth of 4ft. below the track had been completely perforated in a month. In Brooklyn, as in Boston, connection between the return circuit and the corroded service has been tried with some some success. The means for preventing the action in Brooklyn is as yet in an experimental stage, so that proposed extensions of the railway system along the line of one of the largest water-mains in Brooklyn is regarded with anxiety.

Milwaukee has also had her share of trouble from the same cause. O. M. Rau, electrical engineer of the Milwaukee Street Railway Company, tells about it in an article in the *Street Railway Review* in December, 1893. At 2ft. from the power-house on Wells-street a 6in. water-main was so badly corroded after the electric railway had been operating for four years as to render it entirely useless. When taken out of the ground it was so soft in places that a cane could easily be poked through it. In Milwaukee the corrosion was arrested by making numerous low-resistance connections between the pipes and rails, thus keeping the two at the same potential. The connection is made most secure at the pipe station, where both pipes and rails are led to the negative pole of the generator by heavy cables. It is found that as much as 28 per cent. of the total output is now returned by means of the pipes, and no difficulty is encountered. The plan has been working very satisfactorily for over a year.

The Chicago experiences have been set forth in a report made by Prof. Barrett to Mayor Harrison in June, 1893. The destructive effects in Chicago are apparently entirely similar to those of the cities above mentioned. In Prof. Barrett's report some experimental work is referred to, in which a current of ·3 ampere, continued for three weeks, was most destructive to a lead telephone cable, while a cable which was buried in the same soil, but was not subjected to the action of the current, was unaffected.

In Zanesville, O., a 4in. cast-iron water-main was completely perforated in two years. All the neighbouring pipes were affected, some of them lasting only six months.

Columbus, O.; Hamilton, Ont.; Indianapolis, Ind.; Philadelphia; Los Angeles, Cal., and many other cities where considerable electric railway systems are in operation have experienced the same difficulties. In every case the corrosion has exhibited the same general features, and pointed to the same cause.

It is not practically agreed that the reason for the extraordinary corrosion which is referred to here is to be found in the perfect character of the return circuit of the electric railways. When electric railways were first constructed, the rails in connection with the surrounding earth were relied upon to carry all the current back to the generator. It was soon discovered that the current would not confine itself to this path and that the resistance of the earth was far from being as low as was originally supposed. Bonding the rails, cross-bonding, supplementary wires, and ground-plates were then tried. The last were found to be of little avail, while the copper bonds and supplementary wires were often themselves electrolysed, and bond wires up to the present time have frequently been far too small in cross-section for the large current to be carried. The tendency which now obtains, and which is the current one, is to make the return circuit of fully as great conductivity as that of the overhead supply circuit, without relying upon any conductivity from the ground. This is being accomplished by affecting the rail bonds and running heavy track feeders, or electrically welding the rails. There is little doubt that with a perfect return system, which is properly connected to systems of underground pipes, electrolytic disturbances will practically disappear in nearly all cities.

Though the corrosive action of the return current has been so frequently noticed and commented upon, no one has really determined what actually occurs in the ground under the conditions brought about by the operation of electric railway systems. Two theories have been put forward relative to the corrosion: first, that it is simply due to chemical action caused by ammonia, saltpetre, leakage from gas-mains, etc., found in the earth; second, that it is the result of electrolytic action. While simple chemical action undoubtedly has much to do with shortening the life of a pipe, it cannot on the face of it produce effects of the magnitude of these noted above. The ordinary life of water and gas pipes where chemical action alone is met is said to be about 20 years, while the corrosive action with which we are dealing has destroyed new pipes in intervals having from a few weeks to half-a-dozen years' duration. In every case of the corrosion to which we refer, an electric current has travelled along the pipe and the corrosive action has taken place at the point where the current left the pipe. This is conclusive proof of electrolytic action. Secondary chemical reactions play an important part in the final decomposition of the pipe, and these are dependent upon the character of the salts in the soil, but the current sets the ball rolling.

The electrolytic action of the current may occur by means of two processes: (1) direct electrolysis of iron, and (2) electrolysis of chemical compounds which are held in the water of the soil, setting up secondary chemical reactions at the electrodes. In order to have electrolysis at all it is necessary to have the equivalent of an electrolytic cell. In the case of a current leaving a pipe at any point, the pipe is the anode or positive plate of such a cell, the wastes of the soil containing the chemical compounds in solution is the electrolyte, and the rail is the cathode or negative pole of the cell. All corroded iron pipes taken from the earth present practically the same appearance. They are generally "pitted" in many places, and although the pipe is covered with a layer of reddish oxide, the bulk of the corroded metal has generally been entirely carried away in some form or other, presumably by a secondary chemical change.

In order to have the first electrolytic action go on—that is, direct electrolysis of iron—a soluble iron salt must be present in the soil, reaching from anode to cathode. The analysis of street soils shows no such salts, and hence we are safe in concluding that this factor does not enter into the corrosion to any practical extent. The point has been made by several writers on the subject that the phenomenon may be due to the electrolysis of water, the nascent oxygen set free at the anode attacking the iron directly, and forming iron oxide. An examination of the facts of electrolytic action shows that this is not an effect of practical magnitude. This leaves us but one hypothesis to work upon—that is, the electrolysis of substances held in solution in the water of the soils, with a resulting secondary chemical action on the pipes.

In order to determine as exactly as possible what occurs in the soil due to the return current, a series of laboratory experiments were performed, in which the practical conditions were reproduced as fully as possible.

Almost every chemical analysis of street soils shows the presence of some soluble salts of ammonia, potash, soda; and because of their common occurrence an experiment was performed to determine the effect of these salts on the electrolytic corrosion of iron plates per ampere-hour. Six small electrolytic cells were run in series under an electric pressure of about 100 volts, with a current varying from ·2 to ·04 ampere. The cells contained clean glass sand moistened with water containing the salts.

Cell 1 contained NH_4NO_3. (Nitrate of ammonia.)
,, 2 ,, NH_4Cl. (Chloride of ammonia.)
,, 3 ,, KMO_3. (Nitrate of potash.)
,, 4 ,, KCl. (Chloride of potash.)
,, 5 ,, $NaNO_3$. (Nitrate of soda.)
,, 6 ,, NaCl. (Chloride of soda.)

After a run of 14½ hours, the number of ampere-hours was ·7465.

It had been shown by previous experiments upon cells containing these salts that iron was carried off from the positive plates, but was not deposited on the negative plates. The deposit of iron was made in the form of a layer of hydrate or hydroxide of iron near the middle of the cell. The same was true of experiments made with cells containing street soil where only only a comparatively small percentage of carbonates was present. This explains the remark often made in reports of the corrosion of pipes, that the products of the corrosion had disappeared. It was noticed during the experiments that all the cells containing a nitrate gave off a gas at the anode, and this, on being collected, was found to be oxygen. The same cells showed an acid reaction at the anode when tested with methylorange, and the reaction grew less in tensity as the current decreased. In cell No. 1 of the series already referred to, this acidity failed to show itself when the current fell to ·6 ampere, in cell No. 3 at ·045 ampere, and in cell No. 5 it was very faint at ·04 ampere when the current was shut off. The acid reaction and the escape of oxygen in these cells seemed to be associated, and here it becomes necessary to refer to the losses of the anodes in the different cells. It will be seen that the chloride cells exhibit the greater losses, while the nitrate cells show the smaller. Moreover, the cell containing a nitrate in which the formation of acid and oxygen ceased first shows the greatest anode loss; and the one in which it continued to a slight degree to the end of the experiment shows the least. These facts point very strongly to the soundness of the theory of the corrosion which has been finally worked out—namely, in an electrolytic cell with iron electrodes and a soluble salt or salts of the metals of the alkalies or alkaline earths in solution in the electrolyte, the salt is electrolysed by the current, the acid radical attacks the anode, forming an iron salt, while the alkaline metal forms with water a hydroxide at the cathode, liberating hydrogen there. Finally, the meeting by diffusion of these two products precipitates ferrous hydroxide, Fe(OH). As the amount of electrolysis varies with the strength of the current, a comparatively high current will liberate the acid radical more rapidly than it can combine with the iron, the critical point depending upon the affinity of the acid for iron. When this excess is present the radical forms an acid by combining with water and at the same time liberates oxygen. Neither the acid nor the oxygen can combine with the anode, because that is already engaged in the formation of an iron salt with the acid radical, and hence the gas escapes into the air. If the acid is formed in sufficient quantity, it diffuses through the electrolyte, meets the alkaline hydroxide, and forms the original salt and water. In the case of chlorides the nascent chlorine liberated at the anode forms with it a chloride of iron, and if the current is strong enough to form an excess of chlorine it will be dissolved in the water, and may under the influence of light and heat form an acid and liberate oxygen, or, if enough heat is generated, free chlorine will be given off, as is shown by experiment. All conditions of these laboratory experiments are practically parallel in the earth, and hence it is safe to say that similar chemical reactions must go on there. Although the composition of street soils is more complex than the electrolytes of these experiments, they contain the same soluble salts, and as these are diffused through the moist earth they must lend themselves to exactly similar electrolytic influences and chemical changes. In fact, where street soils were used in the experiments as the electrolytes of cells which were placed in series with cells containing known quantities of simple and mixed soluble salts, the losses of the anodes were entirely comparable. It is consequently seen that only such measures as will stop the electrolytic action on salts in solution in the soil can be relied upon to stop the corrosion of iron pipes.

The soil frequently contains carbonate of calcium and magnesium which are dissolved by virtue of the carbonic acid in the water. When carbonates are present in the water to a considerable degree a reddish layer of iron carbonate is found on the pipe. This is generally mistaken by observers for oxide of iron, but we have never found the latter present as a result of electrolytic corrosion. To find the effects of carbonates upon the corrosive powers of soils we ran four electric cells in series. The first two had for electrolytes glass sand moistened with a $\frac{1}{3}$ per cent. solution of chloride of soda in distilled water, and the other two had the same electrolyte with the addition of a solution of carbonate of magnesia and carbonate of lime of uncertain strength. The latter solution was obtained by passing carbonic acid for one and a half hours through water containing equal parts of these carbonates in suspension. The test current was kept at ·09 ampere for seven hours, making ·65 ampere-hour.

The average loss of the anodes of the cells containing chloride of soda alone was ·6565 gramme, while that of the carbonate cells was ·601 gramme. This makes it evident that the presence of the carbonates does not aid in the corrosion of the anode, and even the slight cathode loss due probably to ordinary oxidation is less in these cells than in those containing the chloride only. The difference in the losses of the anode is easily explained. In some previous experiments the loss of anode caused by the electrolysis of a nitrate, a chloride and a mixture of the two was compared. The chloride caused the greatest loss of anode, the nitrate the least, and the mixture caused a loss between the two. In the same way in the case of the carbonate and the chloride, the chloride caused a certain loss of anode, and when mixed with carbonate the loss is somewhat less than when the electrolyte is a chloride alone. The fundamental effect of the carbonates is shown by a further description of the experiment. Soon after the current was turned on, the chloride cells began to show the formation of the ferrous hydroxide layer between the electrodes which has been previously spoken of, while in the other two cells a reddish layer formed at the anode spreading toward the cathode as the action progressed. The reddish layer consisted of carbonate of iron, which was formed by the action of the carbonates upon the products of the electrolysis.

The results of many experiments and the condition of corroded water-pipes as observed lead to the conclusion that under the conditions existing in street soils, the corrosion will primarily go on by virtue of the acid radicals of the hydrochloric, nitric, sulphuric, and other acids, the carbonates held in solution by virtue of the carbonic acid acting merely to change the ferrous salts to the normal iron carbonates and the ferric salts to the ferric hydroxide. Should the carbonates in solution be electrolysed in addition to the salts of the alkaline metals, the carbonic acid radical would not attack the iron, as the corrosive power of the other acids is so much greater, but would again form with the ferrous salts the iron carbonate.

Owing to the doubt which exists as to what minimum voltage is required to induce electrolysis of water-pipes by the railway current, a series of determinations was made by means of the electrolytic cells. The iron electrodes were inserted in clean glass sand 1·5 centimetres apart, and had about 20 square centimetres exposed area. In the first cell a 1 per cent. solution of nitrate of soda was used with a voltage of ·2. As before, the hydroxide layer was formed. The electrolytic action was plain without any other tests. In the following cells the existence of action was shown by chemical tests for the iron salt and the alkaline hydroxide. In the second experiment, a $\frac{1}{3}$ per cent. solution of nitrate of soda was used with five volts. The action was at once apparent.

Cell 3.	Pressure	·25	volt.				Action in	3 min.
,, 4.	,,	·125	,,				,,	5 ,,
,, 5.	,,	·125	,,	$\frac{1}{3}$	per cent.	solution.	,,	5 ,,
,, 6.	,,	·05	,,	,,	,,	,,	,,	40 ,,
,, 7.	,,	·015	,,	,,	,,	,,	,,	50 ,,
,, 8.	,,	·005	,,	,,	,,	,,	,,	1 hour.

In cell 8 the hydroxide layer began to be apparent after one hour.
Cell 9. Pressure ·001 volt. $\frac{1}{3}$ per cent. solution. Action in 1 hour.
,, 10. ,, ·01 ,, Action in 4 hours 45 minutes.
Cell 10. The electrodes were 20mm. apart, and were 40mm. by 68mm. in exposed surface. The electrolyte was street soil.

A surprisingly low voltage produced an appreciable electrolysis in the sand cells. The pressure on cell No. 10

Digitized by Google

might undoubtedly have been reduced to a millivolt without stopping the corrosion, but the resistance of the soil was so high and the percentage of soluble salts so low that the time necessary to produce action would have been considerable. A milliammeter showed a barely perceptible reading in the case of the experiments in which very low pressure was used. The observations plainly show that a mere directive force is necessary to produce electrolysis, and the corrosion is simply a question of current.

It is impossible to give in a reasonable space even a summary of the great number of experiments which were made, but the following conclusions are directly drawn from them:

1. In no case is the action due to the electrolysis of water: where oxygen is liberated at the anode it does not attack the iron.

2. Only a mere directive force in the nature of a pressure will cause electrolysis.

3. The actual corrosion is therefore only dependent upon the actual current which flows, and is as much dependent upon the resistance of the soil as upon the pressure tending to cause the current.

4. Only a minute quantity of soluble salt is sufficient to start the action, and it will then continue as long as a current flows.

5. The gravity of a corrosion of a pipe depends on the amount of current flowing from a given area and the nature of the salts present in the soil, the order of the activity of the salts being (1) chlorides, (2) nitrates, (3) sulphates.

The following table gives the average loss of iron from the anode per ampere-hour, due to different salts and mixtures of salts. It must be remembered that the cathode or negative pole in no case showed a gain, but generally showed a slight effect due to simple oxidation.

Electrolyte—	Loss per ampere-hour.

One ounce is equal to about 28¼ grammes.

The averages emphasise the fact that the chlorides produce the greatest losses of metal, nitrates coming next, the sulphates last, the mixtures in an intermediate place. This seems to show that the power of the acid radical to corrode varies in general as the activity of the corresponding acids.

In I. H. Farnham's paper on "The Destructive Effects of Electrical Currents on Subterranean Metal Pipes," which appeared in the *Transactions* of the American Institute of Electrical Engineers in April, 1894, the statement was made that when the current was reversed every minute extending over a period of 10 days, no material change took place in either during that time. Our experiments have shown that only the positive plate or anode is affected by the electrolytic action which occurs under practical conditions, and hence we should expect that when the current is frequently reversed both plates will be corroded, since they are alternately positive, unless the frequency of reversal is too rapid for chemical action to occur at all. In order to ascertain the effect of such reversals the following experiments were performed. An electrolytic cell was run containing a weak solution of nitrate of soda. The period of reversals ranged from fifteen seconds to five minutes, the current flowing being ·04 ampere under a pressure of three volts. After a few of the quarter-minute reversals, the presence of the iron salt was detected at both plates of potassium ferricyanide tests. On prolonging the periods the iron reaction diminished at one plate and increased at the other during the same period, and *vice versâ* in the following period. When the period of reversal reached 2½ minutes the electrolytic effect was very evident; the iron salt disappeared at one of the plates with each reversal, giving way to alkalinity. The experiments showed that the minimum period of reversal during which corrosion goes on must lie below 15 seconds, which makes the prevention of corrosion by reversals entirely impracticable from this cause alone.

The problem of preventing the destructive electrolytic effects upon iron pipes of the railway return current is shown to consist simply of the prevention of electrolysis of the salts in the soil when the products of electrolysis are of such a nature as to attack iron. It is a problem that requires a careful study of the local conditions in each case before it can be satisfactorily solved. I am quite confident, however, after carefully studying many cases of corrosion and applying the conclusions of these experiments, that there are very few places where the difficulty cannot be avoided by proper construction and arrangement of return circuits. This can ordinarily be done at a comparatively small expense, and with a resulting advantage to the operation of the railway. Some of the conditions that exert the most marked influence upon the corrosion are the nature and amount of the soluble salts in the earth, the resistance of the earth itself in the locality, and the electrical pressure between rails and pipes. High-pressure differences do not necessarily imply a high degree of action, as is shown by the condition of the Madison water-pipes. Here as much as seven volts is found between the rails and the pipes in front of the power station, and yet only a very small amount of corrosion is shown after 1½ years' time. Evidently the resistance of the path here must be very high, or the quantity of soluble nitrates, chlorides, or sulphates is extremely small. The fact that a special and ingenious instrument made to measure the amount of current showed but ·0003 ampere flowing leads to the former conclusion. On the other hand, with the favourable conditions of a low-resistance path between the pipes and the rails, and a relatively large amount of soluble salts in the earth, there is no doubt that serious electrolytic effects may be produced where a quite small difference in pressure exists between the pipe and rails. The extent of the railway system does not always offer a guide to the destructive influences of the return current. Mr. Farnham, in his paper previously referred to, mentions a small road in Rockland, Me., where much damage was done to pipes in five months, while the system in Madison, which is probably fully as extended, shows up to date (a period of nearly two years) a barely appreciable action.

The use of alternating currents, which produce no appreciable electrolysis, would avoid all difficulty, but their use for driving street-railway motors is not, up to the present time, an assured success.

The use of a double-trolley system of conductors would also avoid the major portion of the difficulty, but I believe it can be equally well avoided by proper construction where the usual single-trolley systems are used. This is not a question which has a real bearing upon the discussion of single *versus* double trolley systems. If single-trolley systems were really well built, less talk of double-trolley systems would be heard. One great advantage of double-trolley construction lies in the absolute certainty of its failure if the insulation of the lines is not excellent. Connecting the pipes and rails with heavy cables at points where the former are positive to the latter proves the most complete method of prevention. The conductivity of the track circuit must be properly reinforced by feeders, so that an undue drop is not experienced in the return conductors. These track feeders should always be insulated, and put on the lines exactly as are overhead feeders, in order to save them from corrosion. The connection of pipes and rails has been practically carried out in Milwaukee, Wis., at a cost of about 8,000dol., and has apparently done away with the trouble, and has at the same time decreased the resistance of the return circuit. In the Milwaukee system there is about 125 miles of track, and over 200 cars in daily operation. The track circuit was originally put down in excellent shape. In the Madison system present indications show that one con-

Digitized by Google

nection between rails and pipe systems opposite the power-house, costing all told about 15dol., would prevent any serious action. Investigations have shown that when the negative pole or the generator is connected with the trolley, the pipes are positive to the rails over an extended outlying district, and corrosion goes on over a large area, while with the reversed arrangement the dangerous area is concentrated about the power station. The latter method of connection allows the difficulty to be most easily handled, and after the district within which the pipes are positive to the rails has been accurately determined by proper voltmeter tests, frequent connections of pipes and rails should be made within its limits. This can usually be done at a comparatively small cost, the interest on which may be annually saved by the decrease of lost power if the connections are properly placed. The boundaries of this district should be rechecked from time to time, and the corresponding changes in connections should be made, if the tests show that they are necessary. The outlines of the "danger district" are likely to vary with the growth of the system, and even change slightly with the seasons, and the connecting wires may be eaten away; so that vigilance is here, as everywhere, the price of safety, but safety may be absolutely secured in most cases.

Proper tests with a satisfactorily arranged voltmeter, such as was used in testing the Madison road, seem to give sufficient indications of the density of the current which is leaving the pipes at any exposed point. Such tests, when reinforced by chemical examination of the soil, probably may be used with advantage in determining the extent of the corrosive action which is occurring at any point.

I have not touched upon any argument in regard to the really serious corrosion which has sometimes occurred from other causes than electric railway return circuits. This is a matter which is now generally understood, but is of less magnitude in most cases than the electric corrosion. The owners of pipes are often at fault from the fact that they have filled the soil with electrolysable salts, but even in that case they may generally avoid danger by proper co-operation with the railway companies.

STORAGE BATTERIES.

BY HENRY F. JOEL, A.M.I.C.E.

The recent application of M. Faure for prolongation of his patents has brought this subject of storage batteries into special notice. The important part that Planté and Faure's discoveries have played in the advancement of electric lighting entitle those men to the gratitude of the many electric light engineers and others who have benefited by their labours, and more especially those who, using the pioneer researches of these men as the stepping-stones, have also succeeded in bringing their discoveries into a practical and commercial form—*i.e.*, the modern storage batteries or accumulators; but to Planté and Faure belong the merit of discovering and applying the first practical storage of electrical energy.

The absolute necessity of storage batteries for many installations of electric light, electric power, and the storage of electric energy for medical and other purposes, have induced many inventors to try to improve and perfect the batteries and the constructive details, and it is interesting now to look back and make a *résumé* of the subject, to enable us to find our exact position in the present day, so that we may press onward and continue the progress so worthily inaugurated.

The careful consideration of what has been done, and an examination of the chronological list of patents I have added, will serve to guide the enquirer and inventor in this branch of science, and possibly prevent him from rediscovering and taking out patents for old and exploded ideas and inventions which have already been patented many times over. A brief glance at the chronological list will show how many times almost exactly the same inventions have been patented, at an immense waste of time and money, and it is principally to as far as possible prevent this waste in the future that I have taken the subject in hand.

Before examining the different inventions, and to enable the student to correctly estimate the value of the processes, it will be as well to consider "The Chemistry of Lead Accumulators," taken from Dr. Gladstone and Tribe's book, and other interesting particulars, as follows:

"The sulphuric acid (H_2So_4) would appear to be the electrolyte, because if water only is used no peroxide (PbO_2) is formed.

"The chemical action of the acid on lead plates at first forms sulphate of lead ($PbSO_4$), and does so even with a small current, but a more powerful current causes the sulphate to disappear, and peroxide takes its place on the positive electrode by action of electrolytic oxygen, while the sulphate is reduced to spongy lead by electrolytic hydrogen on negative electrode."

On plates covered with minium (Pb_3O_4), the current reduces and oxidises the material on the respective plates.

The current in charging should not be too strong, as the waste of oxygen under a heavy current become large.

In discharging PbO_2 (neg. plate) | H_2SO_4 (sulphuric acid) | H_2SO_4 (sulphuric acid) | Pb (lead) is converted into = PbO (lead oxide) | H_2O (water) | H_2SO_4 (sulphuric acid) | $PbSO_4$ (sulphate of lead)

which at length becomes $PbSO_4 \mid H_2O \mid H_2O \mid PbSO_4$.

Dr. Frankland says that he considers that the formation depends on the electrolysis of hexabasic sulphuric acid $= SO_6H_6 = SO_3$ (anhydride sulphuric acid) $+ 3H_2O$ (water) which electrolyses as

$$(1)\ SO_6H_6 = \underbrace{\text{eliminated on + electrode}}_{SO_3 + 3O} + \underbrace{\text{eliminated on - electrode}}_{3H_2}$$

In charging, therefore, the chief changes appear to be

1. The electrolysis of SO_6H_6 as equation above (1).
2. The reconversion of SO_3 into SO_6H_6.
3. The chemical action in coating of + electrode
$$SO_4Pb + O + 3OH_2 = PbO_2 + SO_6H_6$$
(lead sulphate) (lead peroxide) (hexabasic sulphuric acid).
4. The chemical action in charging on − electrode
$$SO_4Pb + H_2 + 2OH_2 = Pb + SO_6H_6$$
(lead) (hexabasic sulphuric acid).

In discharging:

1. The electrolysis of SO_6H_6 as in charging.
2. The reconversion as before.
3. The chemical action upon the coating of what was the + electrode, now negative plate.
$PbO_2 + H_2 = PbO + OH_2$ immediately converted into
(lead peroxide) (lead oxide) (water)
$$PbO + SO_6H_6 = SO_4Pb + 3OH_2.$$
4. The chemical action on − electrode now + plate
$$Pb + O + SO_6H_6 = SO_4Pb + 3OH_2,$$

and thus restoring the plates to their original state before charging, and that the strength of the acid is a test for charge in cells if known before charging during discharge. That the most effective strength of acid for economy of conversion of plate is about 1 to 10, somewhere about 1,150 specific gravity.

Faraday said in 1834 of primary batteries "that weak and exhausted charges should never be used at the same time with strong and fresh ones in the different cells." This is more especially the case as regards secondary batteries, where this condition is apt to occur.

MM. Monnier and Guiton estimate that to peroxidise one kilogramme (2·204lb.) of minium it takes 56,560 C.G.S. units = 565,600 coulombs.

MM. Orova and Garbe also say:

Electro equivalent of lead = 1·0867 milligrammes.
" " " sulphuric acid = 0·51445 "

Therefore each coulomb stored up will act on plates, both of them upon 1·0867 milligrammes on each plate, setting free 1·0289 milligrammes of acid at liberty.

This, in practice, is nearly correct, as in a trial case the

Digitized by Google

calculated increase in weight of liquid in cell after charging to actual increase of weight was as 15 to 14, fairly close.

I am indebted to my friend, the late Mr. A. P. Margary (a clever chemist and electrician), in collecting the foregoing description of the chemical changes in storage batteries.

In the list of patents it will be noted that I give several patents before Planté or Faure's describing regenerative primary batteries, with polarising and depolarising materials, etc., and, as I have stated specially in reference to Lontin's patents, these patents anticipate all secondary actions; as a fact, storage batteries, or accumulators, were often described in their early days as secondary batteries, and it is interesting to examine this part of the subject. Leclanché describes a secondary battery: the cell is made with two plates of graphite, or two plates of unoxidisible metal, an electric current is sent through the cell, and it is then capable of giving out an electrical current in the reverse direction. A. Varley and F. H. Varley describe a secondary gas battery with two lead or other plates in a cell filled with acid and water.

Planté describes his battery as follows: "First, of a small secondary pair formed of two lead strips, coiled helically, dipping in a glass vessel filled with water acidulated with 10 per cent. of sulphuric acid, and enclosed in a box," etc., and further states "the secondary pair becomes gradually charged under the action of this battery (speaking of a primary battery) after it has been previously prepared or formed by passing the current of a more powerful battery through it alternately in opposite directions, which action is prolonged for a certain length of time." It is a curious fact that Planté did not claim his battery as a novelty, but only the application for heating and other purposes.

Lontin's battery is described: "To reconstitute a galvanic battery the above-named continuous current is sent through a battery whose action is exhausted in the reverse direction to the current produced by the battery." By this process, for instance, an exhausted Smee's battery, which consists of platinum, zinc, sulphate of zinc, and water is returned to its original form of platinum, zinc, sulphuric acid, and water. Any suitable battery, such as lead with a solution of acetate of lead, could be used under this specification.

Houston and Thomson's description of their secondary battery is remarkable as being a clear exposition of the process of reversing and making primary batteries into secondary batteries.

Faure's invention is the most important of all, from a practical and commercial point of view. Faure clearly describes a quick process for forming the previously well-known Planté secondary battery, "the object in view being to deposit upon the element or upon the two elements a thick layer of metal in a rough and spongy condition, and capable of being oxidised to a considerable depth." It is important to note that it was an essential part of Faure's process to reduce the sulphate of lead first and electrolytically to metallic spongy lead, and then by an after operation to form the oxide or peroxide on the plate. Faure's patent contained beyond doubt the first practical description of the modern commercial storage battery.

Muirhead has the merit of first clearly describing the direct polarisation of plates coated with a paste of red lead by the electrolytic action of a dynamo machine.

I have purposely avoided comparing any of the patents with each other; this paper is intended to be an historical analysis of the subject of storage batteries derived principally from the best authentic source of information—viz., the inventor's own description in his sworn information.

CHRONOLOGICAL LIST OF PATENTS FOR STORAGE BATTERIES.

October 10, 1866 (2623), Brandon (Leclanché).—First patent for accumulator (a voltmeter or gas battery).

July 2, 1869 (2003), Smithers.—Chloride of lead depolariser in primary batteries.

August 25, 1869 (2525), Varley.—Gas battery (lead, etc., plates).

December 19, 1870 (3308), FitzGerald.—Primary batteries. Oxide of metals as depolarisers.

February 15, 1872 (485), Highton.—Primary Batteries. Broken carbon and peroxide of lead.

May 10, 1873 (1713), Clark (Planté).—Planté secondary battery. Lead oxidised and peroxidised by current.

February 3, 1874 (439), Highton. — Regenerative (secondary) battery.

July 14, 1874 (2462), Newton (Leclanché).—Pressure to form solid depolarisers in primary batteries.

February 8, 1875 (473), Clark (Lontin).—Regenerative batteries (secondary). Anticipates all secondary actions with solutions and salts of metal, etc.

October 29, 1878 (4348), Wilson.—Secondary. Iron and salts of metal rich in oxygen.

October 29, 1879 (4460), Lake (Houston and Thomson).—Storage battery. Solution of salts to deposit spongy metal, and regulating charge and discharge.

March 22, 1880 (1234), Clark (Reynier).—Regenerative battery (double fluid).

January 11, 1881 (129), Johnson (Faure). — Faure (augmented Planté). Pastes salt of lead in combination with inert matter (coke) to form spongy lead.

January 10, 1882 (129*), Johnson (Faure).—Disclaims felt and application to vehicles, etc.

March 14, 1881 (1097), Johnson (Société Force, etc., Paris).—Cone electrodes (Planté elements).

April 16, 1881 (1676), Johnson (Faure).—Envelopes for electrodes. Mentions use of red lead and peroxide as depolarisers.

April 22, 1881 (1745), Abel (Jablochkoff).—Oil to assist depolarisation. Electrodes of bundles of fine wire or perforated metal, etc.

May 18, 1881 (2175), Lake (Maiche). — Regenerating batteries (secondary). Claims principle (peroxide of manganese).

May 24, 1881 (2272), Swan.—Cellular plates (filled with finely divided or spongy lead). Claims plates only.

May 26, 1881 (2323), Johnson (Société Force, etc., Belgium).—Fine wire ropes, etc., and porous partitions applied by pressure (lead and woollen cloths, etc).

June 15, 1881 (2606), Muirhead.—Paste of red lead, or peroxide of lead, and polarised by dynamo (first patent for).

June 25, 1881 (2782), Newton (Tommasi). — Cellular plates or electrodes filled with finely-divided lead (lead filings). Claims this also: Lead (and tin extracted) and electrolytically deposited lead.

September 10, 1881 (3926), Sellon.—Disclaims spongy or finely-divided lead oxides, salts, etc.; but claims perforated plates, and use with salts, lead, or compounds.

September 15, 1881 (3987), Sellon.—Alloy of lead and antimony. Cage and other forms of electrodes.

September 16, 1881 (4005), Sellon.—Sheets, foil, gauze, wires, etc. Platinised copper, carbon, etc.

September 19, 1881 (4037), Clark (Kabath).—Kabath battery. Laminated corrugated strips enclosed in perforated frames. Rubber bands.

October 1, 1881 (4255), Watt.—Lead plates, or bunched strips, with electrolytical finely-divided lead, or with Weldon mud (dioxide of manganese), or lead oxide compressed on same with layer of woollen cloth between.

October 10, 1881 (4398), Reddie (Volckmar).—Reticulated or perforated plates, filled in holes with granules or filaments of lead, and then submitted to pressure.

October 13, 1881 (4455), Swan.—Abraded, cut, scraped perforated plates, and also forming same by pressure.

October 18, 1881 (4553), Jensen (Edison).—Regulating the charge and discharge.

October 22, 1881 (4632), Sellon.—Peroxide of lead to save forming, etc.

November 22, 1881 (5104), Clark (Fournier).—Lead plates. Oxide and metallic lead powder, combined by glycerine and moulded.

November 25, 1881 (5159), Crompton and FitzGerald.—Alloy of lead, and removable or decomposible metal or material; makes alloyed plates by pressure.

November 28, 1881 (5198), Biggs and Beaumont.—Claim 1: The construction of chambered cells of finely-divided lead alone, moulded by pressure. Claim 2: Construction of cells of pressed plates of finely-divided lead alone.

December 1, 1881 (5261), Newton (Volckmar).—Horizontal batteries; uses gas to assist action.

December 6, 1881 (5322), Imray (Carpentier and de Pezzer).—Thin bent plates, with corrugations to assist escape of gas; different sized plates, + and −, and soldering edges of plates together.

December 6, 1881 (5338), FitzGerald, Biggs, and Beaumont.—Claim 1: Needle-hole plates. Claim 2: Ditto and folding. Claim 3: Electro-deposited lead fabric folded and pressed. Claim 4: Heat and pressure lead granules and oxides. Claim 5: Woven lead wire chemically treated, folded, and pressed. Mentions lead wire made by drawing or squirting.

December 13, 1881 (5451), Pitkin. — Mentions combination of shreds of lead, and red lead, litharge, and other oxides. Claims electrodes made of lead shavings, shreds, etc., encased in special envelopes with central tangs.

December 14, 1881 (5481), FitzGerald.—Carbon plates pressed, and finely-divided lead and oxides.

December 15, 1881 (5494), Swan.—Makes and reduces white lead, and forms finely-divided lead on electrode.

December 17, 1881 (5521), Grout and Jones —Metallic lead dust compressed upon central plates. Mixes oxide of lead with carbonaceous material, and then heat to reduce oxide to lead.

December 23, 1881 (5631), Sellon.—Terminal plates not oxidisable, carbon, etc.

January 3, 1882 (29), FitzGerald, Biggs, and Beaumont.—Electrolytically removing alloy from compound electrode; blowing into molten lead, etc.

Digitized by Google

January 6, 1882 (72), KENNEDY.—Making large plates, with oxides laid on plates in shallow troughs, and then submitted to current; cuts up into small plates and paints with compound.

January 9, 1882 (120), LIARDET AND DONNITHORNE.—Chemically made, finely-divided lead, and combination with plaster of Paris.

January 18, 1882 (252), LAKE (Tommasi).—Folded lead plates, corrugated and perforated; perforated plate with lead wire bound round, also charging and discharging accumulators.

January 20, 1882 (289), HUMPHREYS.—Venetian blind and lattice plates.

January 21, 1882 (319), SELLON.—Terminal plates of carbon and lead.

February 3, 1882 (538), LAKE (Barrier and Vernède).—Lead tape rolled into round, square, or other flat plates corrugated, paste of litharge and glycerine, platinised charcoal.

February 24, 1882 (905), SWAN.—Makes finely-divided lead from plumbago.

March 25, 1882 (1437), COHNE.—Lead and sulphate of mercury.

April 1, 1882 (1587), TRIBE.—Peroxide of lead plate. Peroxide pressed upon the retaining frame.

April 13, 1882 (1769), JOHNSON (Faure).—Constructing large cells with Portland cement, and supporting plates by hanging tongues.

April 19, 1882 (1875), FITZGERALD, BIGGS, AND BEAUMONT.—Claim 1: Partially oxidised electro-deposited lead compressed into plates. Claim 2: Electro-deposited lead into mould electrode. Claim 3: Porous lead electrodes, with tangs compressed in same.

April 25, 1882 (1946), BOYS.—Finely-divided lead coated with mercury and compressed, making finely-divided lead by violently shaking molten lead.

May 13, 1882 (2263), TRIBE.—Terminals not acted upon; compounds of lead pressed on to plates.

May 25, 1882 (2491), VINCENT (Elphinstone).—Finely-divided lead pressed upon plates (carbon).

June 2, 1882 (2602), BRIGHT.—Porous cells filled with finely-divided lead, shot, etc.; also treating white lead and use of dioxide of lead.

June 12, 1882 (2762), FITZGERALD.—Peroxide of lead and carbon compressed + tin, iron, lead, etc.

June 15, 1882 (2818), SELLON.—Various forms of perforations to lock or key the active material.

June 20, 1882 (2917), PARKER AND ELWELL.—Strips of lead foil coiled and filled with oxide.

June 30, 1882 (3097), WATT.—Makes finely-divided lead from alloy of lead and zinc, made fibrous or woolly by pouring the molten alloy into water, then fills in pores with finely-divided lead and decomposes zinc compressed, makes connection by strips or fingers.

July 1, 1882 (3108), HADDEN (Brush).—Makes electrodes by electrolysis, also from white lead, coates plates with finely-divided lead and oxides by compression, method of charging and discharging.

July 7, 1882 (3220), WOODLEY.—Machine for making lead-wool.

July 7, 1882 (3221), WOODLEY AND JOEL.—Use of lead-wool, and lead-wool mixed with oxide and compressed, to dispense with envelope, asbestos partitions, charging batteries of large surface. Automatic regulation.

July 8, 1882 (3240), SARNEY AND ALPROVIDGE.—Making electrodes of thin sheets of lead, rolling and folding same, coated with oxide, with paper between.

July 11, 1882 (3296), CLARKE (Planté).—Use of nitric acid to form plates; 1 acid to 2 water.

July 21, 1882 (3464), JOHNSON (Sutton).—Carbon plates, acetate of lead solution.

July 21, 1882 (3465), SOMZEE.—Cellular, mesh, or fabric plates, with cavities filled with oxide paste.

August 9, 1882 (3802), KINGZETT.—Read lead +, litharge −, plates or holders of brush-shaped metal, etc.

August 17, 1882 (3961), HANDFORD (Edison).—Arborescent metallic lead, formed from molten lead, coated on plates, or not.

August 18, 1882 (3941), COOKSON.—Lead wires, and coated with deposited lead.

August 18, 1882 (3964), BARNETT.—Finely-divided lead and felt, asbestos, etc., layers packed in boxes or cells; automatic cut-out.

August 19, 1882 (3975), WOODS.—Oxide of copper. Asbestos or woven spun-glass partition.

September 1, 1882 (4178), FITZGERALD AND JONES.—Cathode of carbon and finely-divided lead or oxide of lead; anode substance other than carbon.

September 9, 1882 (4303), FRANKLAND.—Paints or coats electrodes with hardening mixture of oxide and dilute acid; also soaks plates (12 hours) in dilute acid.

September 11, 1882 (4316), CHEESBROUGH.—Electro-depositing spongy lead on to skeleton plates; uses lead hair or fibre; also oxide and peroxide.

September 11, 1882 (4317), CHEESBROUGH.—Comminated powdered carbon and metallic salts; plates and cells filled between them; also sulphate of copper.

September 15, 1882 (4391), COOKSON.—Claim 1: Manufacture of lead filaments by squirting molten lead. Claim 2: Compressing same on to lead strips.

September 18, 1882 (4431), WATT.—Making films or pulveralent lead by the action of a jet of fluid or molten lead and coating fabric.

September 21, 1882 (4511), ANDREWS.—Apparatus for charging and discharging.

October 5, 1882 (4735), KINGZETT.—Caustic soda or alkaline solution, etc., lead, carbon, litharge; also steel, tin, iron, zinc, coated with lead and oxide; also plates, carbon, etc., coated with oxide of iron.

October 6, 1882 (4756), KHOTINSKY.—Peroxide of lead made up with divided lead plates, spongy films, or network of lead.

October 10, 1882 (4809), TATHAM AND HOLLINGS.—Vegetable fibre and finely-divided lead and oxide.

October 19, 1882 (4991), LIARDET AND DONNITHORNE.—Carbon plates, pores filled with lead, also salts of lead and use of finely-divided lead, etc.

October 24th, 1882 (5078), HILLS.—Oxide of lead in powder, and lead plates in cells or divisions.

October 31, 1882 (5183), WOODLEY AND JOEL.—Claim 1: Lead, wool, and oxide, oxide first coated on the sheets of lead. Claim 2: Plate with projecting tongue, with layer of lead, wool, and oxide. Claim 3: Wood veneers. Claims 4 and 5: Automatic charging and discharging.

January 13, 1883 (217), SELLON.—Working and regulating secondary batteries; uses pressure of gas to do so, etc.

March 1, 1883 (1122), FITZGERALD.—Coating and insulating part of electrode.

April 2, 1883 (1644), SELLON.—Acidometer float for automatically cutting out of circuit, etc.

May 1, 1883 (2214), CAPITO.—Voltmeter for regulating charge and discharge.

June 23, 1883 (3123), HOCKHAUSEN.—Regulating charge and discharge, uses hydrometer contact, etc.

August 30, 1883 (4197), FITZGERALD AND JONES.—Alloy of lead and platinum for plates or terminals.

October 1, 1883 (4657), JOEL.—Lead wool enclosed in frames, or clamping trays of plates together by bolts; also Wheatstone bridge regulator.

October 24, 1883 (5069), SELLON.—V-shaped electrodes, with special ridge edges.

December 14, 1883 (5741), SELLON.—Claim 1: Wood or porous division, and elastic clamping frame. Claim 2: Distance pieces made to form clamps. Claim 3: Wood matting. Claim 4: Ditto with elastic connections. Claim 5: Porous tiles of clay and clamped together. Claim 6: Larger size negatives and combination with above.

April 10, 1884 (6228), SELLON.—Saddle-shaped electrodes, inverted cone-shaped, etc.

April 22, 1884 (6646), JOEL.—Claim 1: Alloy of lead and tin. Claim 2: Completely enveloping terminal plate. Claim 3: Electrodes in clamping frames with bolts retained under pressure. Claim 4: Separating division, lattice work, etc. Claim 5: Several means of clamping wood clamps, etc.

July 7, 1884 (9483), HOWARD.—Special holders for electrodes of wood cradles, dovetailed ends, and grooved wood, or perforated wood partitions.

September 2, 1884 (11876), HOWARD.—Dovetailed boxes or cells.

February 9, 1885 (1764), SELLON.—Combination of horizontal and vertical compound perforated and corrugated electrodes.

PRIOR PUBLICATIONS.

1831 to 1838, FARADAY (Experimental Researches in Electricity).—Describes secondary electrolytical action; solution of acetate of lead, producing peroxide of lead. Describes method of producing peroxide of lead. Coats electrode with paste of peroxide of lead, and also red lead to form secondary battery.

June 15, 1843, WHEATSTONE (Royal Society's Bakerian Lecture).—Describes formation of peroxide of lead from decomposing secondary action from a solution of acetate of lead.

1860 to 1879, PLANTE (Researches sur l'Electricity).—Making and describing secondary batteries.

SOME FACTS ABOUT POLYPHASE MOTORS.*

BY LOUIS BELL.

(Concluded from page 221.)

COMPARISON OF A POLYPHASE AND CONTINUOUS-CURRENT MOTOR.

Fig. 2 gives a striking comparison between the properties of the two classes of machines under consideration.

The polyphase motor selected for comparison is of 2 h.p. output, representing the average small motor to be found in central-station practice. This particular size weighs 218lb. complete, and runs at a speed of about 1,400 revolutions per minute on 50 cycles, loaded. It is relatively neither better nor worse than polyphase motors of other sizes, as may be seen by reference to the curves in my previous paper on this general topic. The power factor in this case rises quite sharply, reaching 86 per cent. at half load, and through most of the working range of the motor remains at or near 90 per cent., nearly 91 per cent. as a maximum. The efficiency has its maximum a little under full load of the motor, and reaches nearly 77 per cent., being 75 per cent. at full load. Both power factor and

*A paper read at the Philadelphia meeting of the American Institute of Electrical Engineers.

Digitized by Google

efficiency hold high values from half load up, and do not fall off seriously until some distance below half load.

Contrast with Curves A and B belonging to the polyphase motor, Curves C and D; the former is the efficiency curve of a 2-h.p. 500-volt motor of one of the well-known American makes, and Curve D is a similar curve for 2-h.p. 110-volt motor of European manufacture. These are not selected curves, but were the two completest available. Both these curves, C and D, show remarkable similarity.

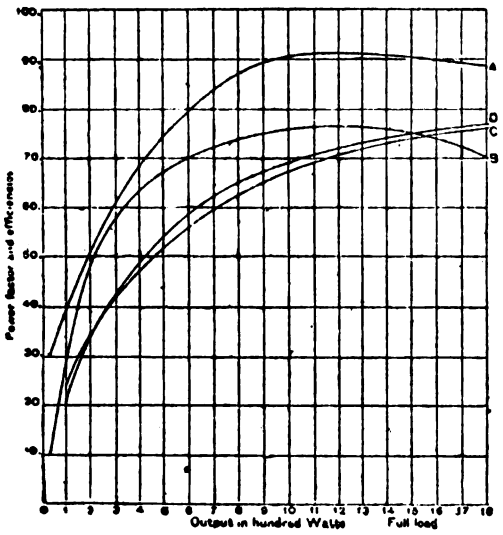

FIG. 2,

Neither of the motors sparked seriously at full load, the load limit being set rather by the heating. Both curves rise slowly, and attain their maximum values at some point beyond the available load of the machine. At full load the efficiency is substantially the same as that of the triphase motor. At low loads it is noticeably worse. I think C and D are fair average average machines. In tests of a wide variety of motors some higher and some lower efficiencies would be found. Such, too, would be the case in testing a variety of polyphase motors. In fact, the mate of the triphase motor shown, sent through the factory at the same time, showed about 1½ per cent. higher efficiency, but a complete test was not attainable, as the machine had to be immediately shipped. A comparison of these curves will render it evident that it is quite practicable to produce a polyphase

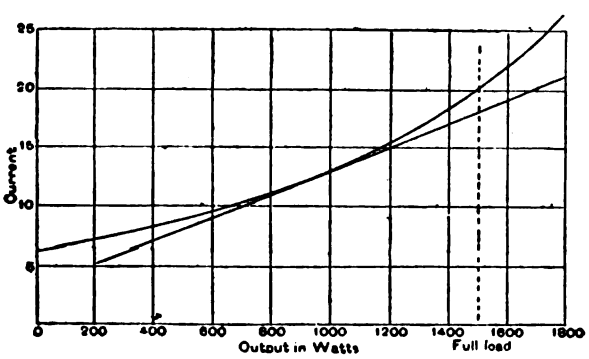

FIG. 3.

motor having an efficiency fully equal to that of direct-current motors of similar size, and I think the tendency will be towards better efficiency at moderate loads. It should be mentioned here that the 2-h.p. triphase motor was made of ordinary good armature iron.

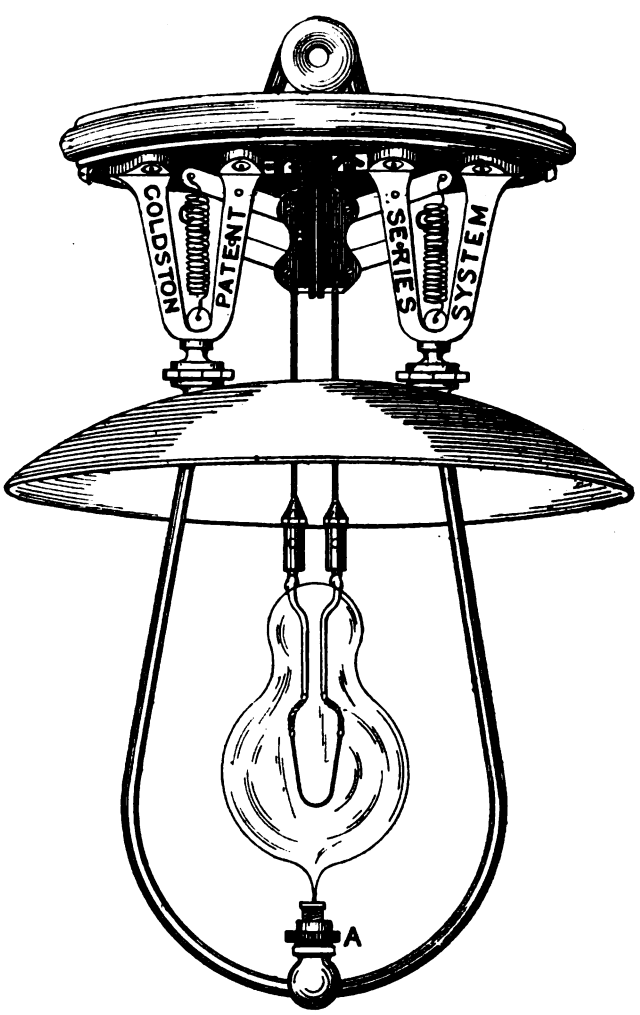
Finally, let me call sharp attention to Curve 3, which shows the effect of the power factor which, I regret to say, has been talked about not wisely but too well in most of the discussions pertaining to polyphase apparatus. Two curves in Fig. 3 show the total current in the line in the 2-h.p. triphase motor, and the 110-volt continuous-current motor above mentioned. The current curve of the continuous-current machine is nearly a straight line—that of the polyphase machine is almost tangent to it and slightly concave upward. A noticeable fact displayed is that throughout the ordinary working range of these two motors the currents were substantially equal, the existence of the power factor in the polyphase motor being only noticeable at very low loads and at overloads. This comparison should be a sufficient answer to the charges of excessive current that have so often been made against the polyphase machines. In a bad polyphase motor they would have foundation in fact. In a rather good one the net effect of the lagging current is trifling. It should further be noted that the current in this triphase motor at friction load is only about 30 per cent. of current at full load, and of this only 30 per cent. represents loss of energy. This is in marked contrast with the results obtained from a foreign triphase motor of similar size exhibited at the World's Fair, in which the no load current was nearly equal to that at full load, and the power factor at full load was barely over 50 per cent.

In this brief discussion of some of the properties of modern polyphase motors I have endeavoured to show how nearly they fulfil the conditions which may be regarded as desirable in electric motors in general. That they do so as well, if not better, than the continuous-current machines of similar capacity I believe that I have satisfactorily shown.

The demand which certainly is arising for polyphase motors for general power purposes based on their intrinsic merits indicates that the older type of machinery has found a dangerous rival, all questions of long-distance transmission aside.

THE "GOLDSTON" SYSTEM OF SERIES INCANDESCENT STREET-LIGHTING.

We called attention in our last issue to a want felt in street-lighting, and we have now to enter upon a description of how invention has attempted to supply that want



The results of any attempt at series incandescent lighting can only be obtained after trial, and we shall not therefore attempt to predict, except that if a really satisfactory system is found it has a good future before it. Mr. Goldston claims to have designed an apparatus which has

Digitized by Google

been tried over a long period of time, though on a small scale, and has been found to be satisfactory. Our illustration is from the latest form of apparatus, a specimen of which was kindly placed at our service by the inventor. The reflector is insulated from the working parts. The action will be best seen by tracing the path of the current. Assume the apparatus in a normal condition. Assume the current to enter by the right-hand terminal, it goes through the flexible wire to the right-hand metal piece, B, through the continuing flexible wire to the lamp terminal, by the carbon filament to the left-hand flexible wire, contact-piece, and left-hand terminal. The bottom of the lamp bulb is continued as a glass rod, and the position of the bulb can be adjusted by means of the screw, A. For normal working it is adjusted so that the contact-pieces, B B, are separated by an air-space. Thus we have the force used in the adjustment opposed to the force exerted by the springs, C C, whichever act to bring the surfaces of B B into contact. The breaking of the bulb or the glass continuation allows the springs to act. B B immediately make good electrical contact, and continuity of circuit is preserved from terminal to terminal. If the carbon is ruptured it is found that an arc is formed, and a little melted metal from the action of the arc on the carbon connections drops upon the point where the glass continuation joins the bulb, and rupture takes place. In any case the arc which is set up travels up the stems, and in cracking the glass at the crown of the lamp, thus releasing the tension, the contact-makers instantly come together. When no automatic regulation is provided to compensate for any lamp being cut out, the apparatus is sent out with carbon faces on the contact-maker, a compensating resistance being thereby inserted simply and automatically. Everything seems exceedingly simple, and as trial has proved it satisfactory we may hope in the very near future of seeing a more extended use of series incandescent lighting.

THE PATHOLOGY AND TREATMENT OF ELECTRIC ACCIDENTS.*

BY W. S. HEDLEY, M.D. EDIN.

If the living body become the path of an electrical current of dangerous magnitude, what are the nature and sequence of the lesions that ensue ; and how may death occur ? Not on account of its connection with lightning stroke, nor because of a ghastly interest it may derive from the process of "electrocution," but because of those accidents that occasionally occur in connection with electric light circuits it is that this question becomes chiefly interesting. It has an obvious practical bearing on the proper treatment to be pursued in attempting the resuscitation of persons injured by such accidents—if, indeed, it be permissible to speak of electrocution as an accident—and to hint at the possibility of reanimation. One of the most useful contributions to a knowledge of this subject is a communication made by M. d'Arsonval in 1877 to the Société de Biologie ; and this has recently been followed up by interesting confirmatory evidence. It is considered that the alternating currents of commerce may cause death in either of two ways : (1) by actual lesion or destruction of tissue ; and (2) by arrest of respiration, producing asphyxia. In the former class death is actual, and nothing can restore animation ; in the latter (including electrocution) death may be, and at first often is, only apparent, recovery still being possible, and even probable, by a timely resort to artificial respiration. The following practical rule is therefore formulated : "Un foudroyé doit être traité comme un noyé." There is a limit, however, to this possibility of recovery. If the elevation of temperature produced by the passage of such currents exceed 45deg. death ensues, "as Claude Bernard has shown, by coagulation of the muscular fibres of the heart."† Should this point have been reached such cases pass into the first category of "mechanical destruction," and are not recoverable ; but in accidents of the kind under consideration the contact is generally of short duration, and the tetanic muscular contractions have not generally lasted long enough to induce the fatal elevation of temperature.‡

It is thus considered that in cases of accidental contact with electric light wires the condition is generally one of suspended animation—of only apparent death—and that by the timely use of artificial respiration real and actual death can often be averted. In attempting the restoration of persons thus injured those repeated rhythmical tractions on the tongue known as the "Laborde" method for the treatment of asphyxia are advocated. It is the procedure which its originator, in his communication to the Academy of Medicine, called "the physiological treatment of death," and its technique is thus described : "With the thumb and index finger, either bare or covered by a handkerchief, the tongue is seized by its anterior third, and powerful repeated rhythmical tractions and relaxations are carried out with a frequency of about 15 to 20 times a minute. In making these tractions it is important to feel that the dragging action affects the root of the tongue. If, in attempting to seize the tongue, it is found that the jaws are closed and the teeth clenched, open them by the finger, if possible, or use as a wedge a piece of wood or the handle of a pocket-knife, or anything of the kind that may be at hand."*

In illustration of the foregoing points an interesting case of recent occurrence is cited. Its details, as given by two electrical engineers who were eye-witnesses of the occurrence, and who assisted in the efforts at restoration, are as follows : It appears that with the voltmeter registering 4,500 volts and an ampere-meter marking 750 milliamperes an alternating current was accidentally short-circuited through the body of a man. The point of entrance was the hand, and that of emergence the buttock. The duration of contact was "certainly many minutes." More than half an hour elapsed before artificial respiration was commenced, and during that time the man showed no sign of life. Arm movements were then carried out, without apparent effect ; on practising the Laborde procedure, however, respiratory movements soon appeared, and in about two hours the man could speak. In the course of a few days he had quite recovered, excepting from the burns at the points of entry and exit. In such accidents the line of treatment to be pursued is sufficiently obvious. It is imperative that artificial respiration be promptly and patiently carried out. The pathology of the accident, however, seems by no means so simple. It is nearly a century and a half since Priestley, experimenting with Leyden jar discharges, showed that death might result from "electric shock" without structural lesion. Recent experiments, especially in electrocution, have abundantly demonstrated this. Such cases might perhaps come under d'Arsonval's second class, and it is allowable to speculate how far the result might have been averted by a timely resort to artificial respiration. How, then, in the absence of actual destruction of vital structures, may such accidents injure or kill ? What part do the lungs, heart, and nervous system respectively play in the morbid process ? How far is the process direct, or reflex, or inhibitory ? Stimuli applied through the vagus or "almost any afferent nerve" will, by reflex effects through the bulb, influence respiration, and it may probably be accepted that, if the stimulation be very strong, respiratory action may be arrested in inspiratory tetanus. So far as the heart is concerned, the inhibitory action of the vagus will come into play. Ziemssen showed in his "classic" experiments that tentanising induction currents applied to the heart of the dog produced those irregular, arhythmic, fibrillar contractions spoken of as "delirium cordis," "caused by some change in the muscular fibres themselves." Is this change a coagulation by the heat resulting from the tetanic muscular contractions ? The further experiments of Ziemssen with currents applied directly to the human heart with only pericardiam intervening, as well as the experiments of Ludwig and Hoffa, of Biedermann, MacWilliam, Herbert, and Dixon Mann, are familiar through the text-books of physiology. Such experiments may possibly serve as a guide to ordinary therapeutic work or as a starting point in the controversy as to the risks of vagus stimulation in such conditions as chloroform narcosis or other intoxications ; but they will not tell us how a modern industrial current may injure or kill. Further direct experimentation ought to be taken up from the point where the above-named investigators have left it. Cardiographic and respiratory tracings are wanted to show in sequence of time the nature and extent of the influence on circulation, respiration, and innervation of modern currents under various conditions of contact, strength, direction, and duration.

* The *Lancet*.

† According to Halliburton, *myosinigen* coagulates at 56deg.

‡ M. d'Arsonval points out that the elevation of the central temperature produced by the passage of these strong currents is not due to the "resistance of the body to the passing current, in conformity with the laws of Joule, but to the violent contractions throughout the whole of the muscular system, and also to the condition of asphyxia, as Dr. Brown-Séquard has shown."

* "If the case be one of drowning, at the beginning of the proceeding, whilst holding the tongue with one hand, pass the index finger of the other hand to the back of the fauces to induce vomiting, and clear the stomach as far as possible from water, food, etc."

Electric Deck Planers.—Messrs. Mavor and Coulson, of Glasgow, have just shipped one of Sutherland's electric deck planers to Messrs. Cramp, of Philidelphia. This is the second planer purchased by that firm.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIII. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

ELECTRICITY IN FACTORIES.

The recent meeting of the Iron and Steel Institute at Brussels directed attention once more to the value of electricity for power purposes. A brief description of the installation at the National Arms Factory at Herstal, near Liège, was given by Mr D. Selby-Bigge in his paper, an abstract of which appeared in our last issue. Great interest was shown in this description, and some members were heard to admit that they visited Belgium and the meeting solely for the purpose of visiting Herstal and examining the installation. Although the author summed up the advantages to be derived from electric driving, there was one of considerable importance which might have been made more prominent. We give Mr. D. Selby-Bigge's summary of advantages:

1. The concentration in one highly economical plant of the generation of power for the whole of the works, and great reduction in coal consumed per unit of work done.

2. Reduction in wages, owing to the very small number of officials required in connection with such a plant.

3. Transmission of the energy generated, with very trifling loss, to the different parts of the works.

4. Absence of main shafting, counter-shafting, pulleys, bearings, and belts, and heavy cost of up-keep in connection therewith.

5. Absence of long lengths of steam-pipes, and losses due to condensation.

6. Absence of scattered and separate boilers.

7. Absolute control over the economical running of the works owing to the self-indicating nature of electric motors, and the immediate detection of any undue losses which so often occur in mechanical forms of power transmission.

8. Great economy in work of an intermittent nature and varying loads, a direct proportion between the indicated horse-power of generating engine and work given out by motors being obtained.

9. Very small cost and size of foundations involved in works driven electrically.

10. Great facility for alterations and extensions, without any modification being necessary to the original plant.

It seems to us that more ought to be made of the point that with electric motors there is no loss due to the constant rotation of shafting, belts, and loose pulleys. The work demand is intermittent, but in an ordinary factory with a multiplicity of shops and tools, the shafting, belts, and loose pulleys are constantly running. It would not be difficult to ascertain the loss thereby occasioned. Indicator diagrams might be taken with all these running and no tools on, thus getting the constant demand on the engines not required in actuating the tools for doing work. The cost of driving a tool by electricity may at present and when taking the prices charged by supply companies seem and actually prove greater than the cost of steam for similar work, but the larger part of the cost of electricity stops as the tool stops; and when this is taken into consideration we fancy that the total annual cost of electric driving will, in the majority of cases, turn out to be less than that of steam driving.

Digitized by Google

Many householders have to acknowledge that the "use only when required as light" has really diminished their light bills where electricity has replaced gas. The mistress and the maids switch on when required and switch off when not required, instead of lighting the gas in the early evening and leaving it burning till bedtime.

But besides the information given by Mr. Selby-Bigge, the many hundreds of engineers who visited the Cockerill Works at Seraing were somewhat astonished to see a sixty-ton travelling crane worked electrically. This is one of the largest, if not the largest, cranes so worked, and the ease with which it was manipulated, as well as the manner in which it did its work, caused such working to be looked upon with favour by many who had previously scoffed. There was a prevalent idea in many minds that with electricity stoppages and hitches of various kinds were constant, but these views have, we think, been almost entirely removed by actual examination. The value of this visit of the Iron and Steel Institute to Brussels upon the prospects of electrical development cannot be over-estimated. We have never been inclined to prophesy unless we know, but in this case we are certain that many prejudices have been overcome, many eyes enlightened, and that there will be less hesitation in future among the six hundred or so of the members who took part in these proceedings to test the value of electrical work in their own factories. After all, men are in some things very much like sheep, inclined to follow a leader. Individually they hesitate to take a new departure, and wait for some of their fellows to take the initiative. This is, however, but natural, for many new departures prove failures, and a return to the old paths is necessary; thus comes the inclination to let someone—not me—bear the racket of proving the new thing a success or a failure. "If it is a failure," says the individual, "I save my money. If it is a success, why I shall only be a short way behind." It is this feeling that keeps many men from going ahead, and while caution of a certain type may be commended, it is not so certain that caution of another type is advantageous. Were all men endowed with this spirit of following, there would be little progress, but the bolder spirits, and those who have more confidence in themselves, prefer to be in the first flight, well knowing that being first in the field never tells against them in business matters. It is always a gain, and the gain compensates the risk. Thus it is to be hoped that many who have held aloof will in the near future try the electrical distribution of power, and we are sure the trial, if made under due precautions, will prove satisfactory to all concerned.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

STREET-LIGHTING WITH INCANDESCENT LAMPS.

SIR,—Your article in your issue of the 24th points out that "the real solution of the problem seems to turn upon the introduction of a satisfactory method of lighting incandescent lamps in series," and that the difficulties of placing street lamps on the ordinary low-pressure mains that serve for house-lighting, etc., seems to point to a series system "as being the most likely to give satisfaction with economy." You add that, "after all, it only means the devising of a reliable and efficient cut-out for incandescent lamps—automatic in action, cheap, and simple to construct."

May I draw the attention of your readers to the fact that all the desiderata you mention already exist in Mr. Goldston's system of series incandescent lighting for public streets, of which I enclose you the printed description (with a drawing) which can be applied at this moment in any system of distribution, either alternating or continuous, which employs a current of 750 volts and upwards.

This has already been brought by me to the notice of all the municipal engineers interested in electric lighting; and as the time arrives for them to take up the question, I hope they will put themselves in communication with me.—Yours, etc., C. E. WEBBER.

London, E.C., August, 27, 1894.

[A description of this lamp mentioned is given in another column.—ED. *E.E.*]

AGEING AND MATURING BRANDY BY OZONE.

SIR,—I do not know what is the Brandy Distillers Association to whom you refer in your last issue, but it strikes me that its process for ageing brandy by ozone is extremely slow.

If maturing and improving brandies takes 18 months, the only conclusion to be arrived at is that the apparatus used are very imperfect, and produce a very poor quantity of ozone.

With a medium-sized apparatus a cask of wine or spirit can be ozonised within from four to six hours, according to the quality of the liquid, and after some weeks' rest—say three months—connoisseurs will declare that the ozone will have given a few years to the wine or spirits.

Any person who may desire to ascertain the accuracy of my statement has simply to send a small or large cask of new port wine or brandy or whisky to my works, 7, Letchford-buildings, Bethnal Green, E., where, in his presence, the wine or spirits will be ozonised and the vessels sealed, and two or three months after the liquids will be tasted and a decision given.

Not only is the expense in ageing and improving wines and whiskies or brandies trifling, but this maturing and refining of alcoholic liquids is rapid, and thus realises a great economy based on the quick turnover and on the saving of the loss by interest on capital and of the shrinkage, which always takes place by evaporation.

If ozone is applied to wines and spirits, there must be no question of waiting 18 months for the results. Eighteen weeks is already too much. E. ANDREOLI.

London, August 25, 1894.

PERSONAL.

Sir,—A circular letter, written by a gentleman with whom I was for some years connected, has been sent round which so evidently refers to myself that I feel bound to take notice of it, and should be glad if you will allow me to correct, through your columns, inferences made therein.

When I left that gentleman he was aware that I intended starting in business for myself, and also that I intended issuing a register. These things were not done without his knowledge, and as, by his statement, he found it necessary to part with me, he did so quite knowing what I was about to do, and our parting was on the most friendly terms, and as he expressed a wish that we should have business transactions together, some apparatus which were his property were put in my register, so that if he could not dispose of them I might be able to do so for him. As regards the mention of his name, I do not consider that there could be the least objection to my stating that I had left that gentleman, and it was only in this way that the name was mentioned. As regards the alteration of address, when I first commenced, and before I had taken a City

Digitized by Google

office, I had sent out notices from my country address, and the attention was called in my register to the change to the City address. As the letter was so evidently issued for the purpose of injuring me, I am bound, though with very much regret, to correct statements made with this palpable intention.—Yours, etc., G. E. PIGGOTT.

110, Cannon-street, E.C., August 28.

LOWRIE'S INTRAPOSED SYSTEM.

SIR,—My opinion of Mr. Lowrie's compound intraposed automatic system was, as mentioned, based upon a description contained in your journal of the 27th ult. As Mr. Lowrie says that his switch works all right, I must conclude that the description was not a correct abstract from the specification. If so, I hope Mr. Lowrie will correct this abstract, the more so because the point mentioned in my letter was not the only one which seemed to show a want of knowledge of the working of a transformer. I had good reason for believing that Mr. Lowrie's system was one of the numerous inventions which are patented before thorough experiments are made, as it has been pointed out on several occasions in the *Electrical Review* that the system had not yet been subjected to a practical test. I am glad to learn that I have been under a misapprehension in this respect. I am afraid I have been somewhat misled by the name of the system; as a rule the value of a patent is inversely proportional to the square of the length of its name.—Yours, etc., S. A. FABER.

August 27, 1894.

CITY AND GUILDS OF LONDON INSTITUTE.

We have received from Messrs. Whittaker and Co., the publishers, a copy (price 10d.) of the programme of technological examinations, etc., for the session 1894-5. It may interest many of our younger readers to know exactly what the examination demands, and, while not seeking to lay too much stress upon the value of examinations, we must point out that in combination with practical work they may be enormously beneficial. The ability to answer examination questions proves a man to have a specific as well as a general knowledge of his subject. We have often said the average Englishman is neither a reader nor a student. He ought to be both. Hitherto he has thought it a grand thing to be as good as anybody else. In the struggle for existence this will not do. To succeed you must aim to be better in something than your competitors, and having achieved that distinction, you are taken from the ruck and stand upon a pedestal whereon there is not such fierce competition. Here is the syllabus for "Electric Lighting and Power Transmission":—

With the view of encouraging artisans to take a complete course of instruction in this subject, an elementary examination will be held preliminary to that in the ordinary grade. No certificates will be given to cadidates on the results of this preliminary examination, but their successes will be notified to the centre at which they were examined. Candidates may take the ordinary grade without having passed the preliminary, or both examinations may be taken in the same year. Those who pass the preliminary examination as well as the examination in the ordinary grade (whether in the same year or in a previous year) will not be required to produce a Science and Art Department's certificate in the subject of electricity and magnetism before they are eligible for the full technological certificate. In the preliminary examination no questions of a mathematical nature will be set, nor any involving calculations beyond the ordinary rules of arithmetic as applied to such matters as Ohm's law; nor will any questions be asked concerning the chemical applications of electric currents.

The preliminary examination will be held on Wednesday, May 1, from 7 to 10.

In the ordinary grade questions will be set that presuppose an acquaintance with elementary algebra, including quadratic equations, and a knowledge of the simple trigonometrical quantities, sine, cosine, etc. The candidate must be able to plot values in the form of curves. He is strongly recommended to learn the use of the slide-rule, and should bring one to the examination, or he may use in calculation a table of four-figure logarithms. Greater accuracy in working out examples than can be obtained by the use of the slide rule is not required. In marking the answers the examiners will take note not only of the correctness of the results, but also of the methods used. Simple common-sense methods, in which the general accuracy of the work can be tested step by step, are to be preferred to the use of long and complicated formulæ. Candidates are expected to be able to make simple hand sketches showing sizes of parts.

The examination in the ordinary grade will be held on Monday, May 6, from seven to ten.

In the honours grade there are three sections corresponding to the three main branches of the electrical engineering industry. The candidate must elect for himself in which of the three sections he desires to be examined. The examination will be confined solely to the single section he selects, and any questions may be asked on the subjects contained in this section, such as can be answered by a practical electrical engineer who has devoted himself specially to these subjects. In the honours grade the candidate may during the examination use an electrical engineering pocket-book; but if he avails himself of this, he must state the title of the book on his answer paper, and in his answers give references to the pages of the book he has consulted.

The examination in the honours grade will be held on Monday, May 6, from seven to ten.

I. Syllabus.—The preliminary examination will include questions founded on the following subjects:

1. General notions about electromotive force, current, resistance, and the principles of electric circuits, simple and branching. The voltage required to produce any required current in a wire of given resistance.

2. The construction and action of electric bells; the arrangements of battery cells and of circuit for bells.

3. General descriptive knowledge of magnets and electromagnets. Best methods of winding electromagnet coils for various services.

4. Simple principles and use of electric measuring instruments: ampere-meters, voltmeters, delicate mirror galvanometers, resistance coils.

5. The induction of currents by motion of magnets. Notions about magnetic lines of force. Magneto-generators for electric bells. Simple descriptive knowledge of the common sorts of dynamos and alternators.

6. The induction of currents by action of currents in neighbouring circuits. The effect of iron cores. Simple descriptive knowledge of induction coils and of transformers for alternate currents.

7. Simple principles of electric motors and of electromagnetic mechanism. The magnetic drag on wires carrying currents.

8. Elementary descriptive knowledge about incandescent lamps and arc lamps, and their arrangement in parallel and in series. The necessary parts of arc lamps, and their action.

9. The relations between mass, weight, and force. Distinction between work and power. Relations between heat and work. Relation between the watt, the kilowatt, and the horse-power. Wattmeters.

ORDINARY GRADE.

In addition to the foregoing, candidates for the ordinary grade certificate are expected to be acquainted with the following matters, except the parts contained in brackets [ ].

1. Comparison between the British units of mechanical measurement, and the international units based on the centimetre and the gramme.

2. The laws of Ohm and of Faraday respecting steady currents. [Laws of Helmholtz and of Maxwell respecting sudden and periodic currents.]

3. Electric measuring instruments for the laboratory, and the manner of using them. Wheatstone's bridge. Standards of resistance, electromotive force, and capacity.

Digitized by Google

4. Practical ampere-meters, voltmeters, and wattmeters. Electro-dynamo-meters, current balances, electrostatic voltmeters, hot-wire instruments.

5. Magnetic properties of materials, magnetising force, induction and permeability. Hysteresis. [Methods to determine these quantities.]

6. The solenoid and its properties. The electromagnet [and its adaptations to electro-mechanical devices].

7. Mechanical strength and electric properties of materials. Conductivity of metals and alloys, and its change with temperature. Mechanical qualities and resistance of insulating materials, and the influence of temperature. [Testing of insulation resistance. Ohm meters.]

8. Condensers. Work stored in a condenser. [Dielectric strength of insulating materials and its relation to mechanical strength, incombustibility, and specific inductive capacity.]

9. Fundamental points of magneto-electric induction. Self and mutual induction. [Induction balances. Standards of self-induction. Secohm-meters.]

10. Outline of theory of continuous-current dynamos and motors. Characteristic curves.

11. The magnetic circuit as applied to dynamo machines. Types of field magnets and armatures, considered magnetically.

12. The winding of field magnets and armatures.

13. The mechanical features of dynamos and motors as regards strength of parts, heating, durability, ease of repair, construction of brushes, commutators, terminals, etc.

14. Motor generators, fundamental rules as to winding, speed, and output.

15. The electrical and mechanical efficiency of dynamos and motors. [Methods of determining efficiency.]

16. The construction [and theory] of alternators and transformers. [Alternate-current motors.]

17. [The efficiency of alternate-current apparatus.]

18. The transmission of power by direct currents over moderate distances.

19. Practical method of arranging lamps and circuits.

20. Incandescent lamps and arc lamps, watts per candle. [Photometry, illumination of rooms and open spaces.]

21. Secondary batteries, construction, use and theory.

22. Distribution of electrical energy from central stations direct and transformer systems, continuous and alternating currents, two-wire and multiple-wire mains.

[23. Central stations. Load diagrams. Conduits.]

HONOURS GRADE.

Candidates for Honours must have previously passed in the ordinary grade.

Candidates will be examined in one of the following sections:

Section I.—Electrical instruments and regulating appliances; their construction, use, etc.; or

Section II.—Dynamos, motors, accumulators, and transformers; their construction, use, etc; or

Section III.—Light and power distribution, mains, and central stations.

The candidate for the Honours Grade Examination must elect in which of the three sections he desires to be examined. The examination will be confined solely to the single section he selects, and any questions may be asked on the subjects contained in this section, such as can be answered by a practical electrical engineer who has devoted himself specially to these subjects.

SECTION I.—ELECTRICAL INSTRUMENTS, ETC.

More difficult questions will be set in subjects 1 to 8 inclusive, including the subjects contained in brackets, and in addition, a knowledge will be required of: Galvanometers, sensitive, aperiodic, astatic, differential, ballistic. The use of shunts, the calibration of instruments. Measurement of very large and very small resistances. Switchboards; safety devices; automatic regulators. Portable instruments for electric and magnetic measurements and photometry.

SECTION II.—DYNAMOS, ETC.

More difficult questions will be set in subjects 5, 6, 7, 9, 10, 11, 12, 13, 14, 15, 16, 19, 20, including those in brackets, and in addition a knowledge will be required of; the designing of dynamos for arc and incandescent lighting, of alternators and transformers; predetermination of characteristics; armature reaction; causes of heating and sparking of machines; parallel working of alternators; the construction of motors for special purposes and gearing of same.

SECTION III.—ELECTRIC LIGHT AND POWER.

More difficult questions will be set in subjects 4, 9, 12, 13, 14, 17, 18, 19, 20, 21, including those in brackets, and in addition a knowledge will be required of electric transmission and distribution of power by continuous and alternating currents; electric railways and tramways; private electric light installations; the electrical equipment of central stations, including arrangement of dynamos, batteries, switchboard, and regulating appliances; overhead and underground mains; safety devices, testing devices, fire office rules; size of the feeders and mains in the two and three wire systems; use of sub-stations.

II. Full Technological Certificate.—A provisional certificate will be granted on the results of the above examination. For the full technological certificate in the ordinary grade the candidate who is not otherwise qualified (see above and rules 41-2) will also be required to have passed the Science and Art Department's examination in the elementary stage at least, and for the full certificate in the honours grade in the advanced stage at least, in two of the following science subjects: II., machine construction and drawing; V., mathematics; VI., theoretical mechanics; VII., applied mechanics; VIII., sound, light, and heat; IX., magnetism and electricity.

In connection with these examinations, it has been decided during the winter season to give a series of articles or lectures for the benefit of students who are unable to attend classes.

ELECTRIC CONDUCTORS FOR COAL MINES.

In the "Foreign Abstracts" of the Institution of Civil Engineers, a paper is given by Mr. J. Libert on this subject. The author states that until recently, safety lamps, using vegetable oil, were required by law to be used in all Belgian mines, and by implication electric lighting was forbidden. Lately this restriction has been removed, and it has become important to consider what kind of conductors afford the greatest degree of safety against the ignition of fire-damp, this being very common in Belgian mines. The principal danger to be guarded against is the production of sparks in case of any accident, from falling stone or otherwise, happening to the cable. The attempts that have so far been made to avoid this danger have all proceeded on the lines of dividing the current into two parts, a main and a secondary current, whose conductors are in the same envelope. These conductors are so made that in case of a rupture of the cable, one must break before the other. The first effect of the accident, then, is to throw a sudden increase of current on the line which remains unbroken, at any rate for a short while, and this increase of current is made either to interrupt or short-circuit the current outside the mine, so that the subsequent breakage of the other conductor can do no harm. In the first safety cable of this kind—viz., Atkinson's—the conductor for the auxiliary current is formed of a spiral of wires which will stretch to a great extent without breaking. A fusible plug interposed in this auxiliary circuit cuts off the current whenever the breakage of the main conductor has thrown extra current into the auxiliary circuit. The "Charleton" safety cable has the auxiliary conductor so stretched that it will break before the principal conductor, and its breakage will interrupt by electromagnetic action the current. Another cable, which it is the principal object of the paper to describe, has been invented by Mr. Nolet. It is in sections, so that any section can, if necessary, be detached for repairs. The sections are coupled by sleeves, the principal and auxiliary conductor having each its own sleeve. These sleeves slide freely on the conductors, and are very different in length, so that any accident tending to break the cable will first interrupt the auxiliary current, and this interruption, by electromagnetic appliances, will

Digitized by Google

interrupt the main current outside the mine, where any spark would be harmless. The auxiliary conductor is a wire, and the main conductor a tube surrounding it, insulated outside and in. The auxiliary current travels in the opposite sense to that of the main current. Any other accident, such as crushing or cutting of the cable, so as to produce a contact of the principal and auxiliary conductors would equally interrupt the current before over-heating or sparking could occur. By putting in an earth connection at the middle of the auxiliary conductor, the apparatus will serve to detect any serious leakage in the main conductor.

PRACTICAL NOTES ON DYNAMO CALCULATION.*

IX.

BY ALFRED E. WIENER.

(Continued from page 157.)

By comparing the values of J found from (49) with the average given in the following Table XXXI. the rise of the armature temperature can be approximately determined, and thus a measure for the electrical quality of the armature be gained. The quality of the proportion between the armature winding and the dimensions of the core is indicated by the amount of increase of the armature temperature. If the latter is too high, it can be concluded that the winding is proportioned excessively, and either should be reduced or divided over a larger armature surface.

TABLE XXXI.—Rise of Armature Temperature Corresponding to Various Circumferential Current Densities.

Circumferential current density.	Rise of armature temperature in deg. C. High-speed (belt-driven) dynamos.	Slow-speed (direct-driven) dynamos.
50 to 100	15 to 25	10 to 20
100 ,, 200	20 ,, 35	15 ,, 25
200 ,, 300	30 ,, 50	20 ,, 35
300 ,, 400	40 ,, 60	25 ,, 40
400 ,, 500	50 ,, 70	30 ,, 45
500 ,, 600	60 ,, 80	35 ,, 50
600 ,, 700	70 ,, 90	40 ,, 60
700 ,, 800	80 ,,100	50 ,, 70

The difference in the temperature rise at same circumferential current density for high-speed and low-speed dynamos (columns 2 and 3 respectively of the above table) is due to the fact that, other conditions being equal, in a slow-speed machine less energy is absorbed by hysteresis and eddy currents; that consequently less total heat is generated in the armature, and, therefore, more cooling surface is available for the radiation of every degree of heat generated.

20. *Load Limit and Maximum Safe Output of Armatures.*—From Table XXXI. also follows that, according to the temperature increase desired, the load carried by an armature varies between 50 and 800 amperes per inch of circumference, or between about 150 and 2,500 amperes per inch of armature diameter. As a limiting value for safe working, Esson† gives 1,000 amperes per inch diameter for ring armatures, and 1,500 amperes for drums. Kapp‡ allows 2,000 amperes diametral current density for diameters over 12in. as a safe load.

Taking 1,900 amperes per inch diameter (= 600 amperes per inch circumference) as the average limiting value of the armature load, corresponding to a temperature rise of about 70deg. to 80deg. C. (see Table XXXI.), we have

$$K \times \frac{C}{2P} = 1{,}900 \times d_a \quad . \quad . \quad . \quad (50)$$

and since for the output of a dynamo we can write (see Part II., chap. 1)

$$W = E \times C = \frac{K \times \Phi \times N}{P \times 10^8 \times 60} \times C \quad . \quad . \quad (51)$$

in which

W = the output of dynamo in watts;
E = total E.M.F. generated in armature in volts;
C = total current ,, ,, ,, amperes;
K = number of armature conductors;
Φ = number of useful lines of force;
N = speed in revolutions per minute;
P = half number of parallel armature circuits (number of pairs of poles).

We obtain for the limit of the output by inserting (50) into (51):

$$W = \frac{1{,}900 \times d_a \times \Phi \times N}{10^8 \times 30} = \frac{63 \times d_a \times \Phi \times N}{10^8} \quad (52)$$

But the useful flux, Φ, is the product of gap area and field density, or

$$\Phi = \frac{d_a \times \pi}{2} \times \beta' \times l_a \times \mathfrak{B},$$

and consequently (52) becomes

$$W = \frac{63 \times d_a \times \frac{d_a \times \pi}{2} \times \beta' \times l_a \times \mathfrak{B} \times N}{10^8}$$

$$= d_a^2 \times l_a \times \beta' \mathfrak{B} \times N \times 10^{-6} \quad . \quad (53)$$

W = maximal safe output of armature, in watts;
d_a = diameter of armature core, in inches;
l_a = length ,, ,, ,,
β' = percentage of useful gap circumference; to be taken somewhat higher than percentage of polar arc to allow for circumferential spread of the lines of force (see Table XXXII.);
$\mathfrak{B}$ = Field density, in lines of force per square inch;
N = Speed in revs. per minute.

Average values for β' taken from practice are given in the following table:

TABLE XXXII.—Percentage of Effective Gap Circumference for Various Ratios of Polar Arc.

Percentage of polar arc, β.	Percentage of effective gap circumference, β'. 2 poles.	4 to 6 poles.	8 to 12 poles.	14 to 30 poles.

REPORT ON DRY CELLS.

THE E.C.C. AND OBACH CELLS.

In our issue of August 3, we referred to the report prepared by Prof. Andrew Jamieson, M.I.C.E, on dry cells of the Obach and E.C.C. types, and promised to again refer to the subject on a future occasion. We now take the opportunity of dealing with the matter. There were two series of tests—these being taken by Messrs. David A. Ramsey, John Burns, and James Macgregor.

The first series of tests were made with a No. 2 E.C.C. cell weighing 2lb. 2oz., and of the following dimensions, 16·5cm. by 6·5cm. diameter; and with a No. B Obach cell weighing 2lb. 10oz. and 15·6cm. by 6·5cm. in diameter. The tests were taken in order to determine (1) potential current, the variation of the potential difference at the terminals of each cell due to the variation of the current strength in its external circuit; (2) potential time, fall of potential while on closed circuit and maintaining approximately the same current throughout the whole test; (3) total output in ampere-hours, discharging through a constant resistance until practically exhausted.

Two galvanometers were used—one of very high resistance as a voltmeter, and the other of very low resistance as an ammeter. The high-resistance astatic mirror galvanometer of 26,000 ohms (which was used as the voltmeter) had in circuit with it a resistance of 100,000 ohms, so that the total resistance was about 126,000 ohms. It was so controlled that a new Latimer Clark's standard cell of 1·454 volts at 15deg. C. produced a deflection of 300 scale divisions. Consequently, one scale division = $\frac{1}{3}\cdot\frac{1}{4}\frac{1}{5}^4$ or ·0048 volt. The low-resistance mirror galvanometer was under strong magnetic control and shunted by a short thick copper wire. It was then carefully calibrated for milliamperes by the college Kelvin balance. Paraffin blocks with mercury-cups were used as switches, and the connections were made by stout copper wires.

The total output in the case of the Obach cell was 17·4 ampere-hours, and with the E.C.C. No. 2 cell 15·1 ampere-hours, being an excess of Obach over E.C.C. of 2·3 ampere-hours.

The second series of tests is quoted from the report as follows:

A new pair of cells was used for this series of tests—namely, an Obach A and an E.C.C. No. 1.

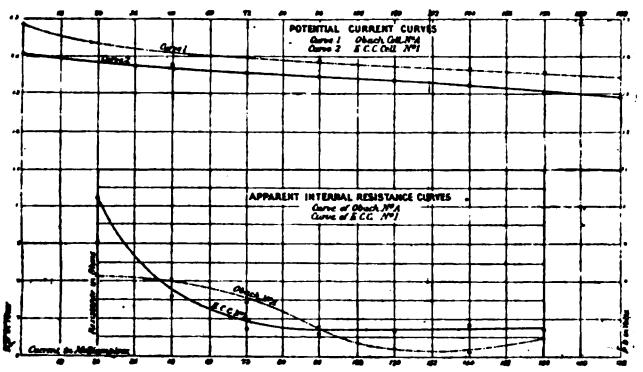
Digitized by Google

TABLE I.—Weights and Dimensions.

	Weight.	Dimensions.
Obach A	4lb. 6oz.	7¼" × 3⅛" diameter.
E.C.C. No. 1..	3lb. 9oz.	7¼" × 3⅛" diameter.

The tests taken were as follows: (1) potential current; (2) internal resistance; (3) total output in ampere-hours and watt-hours; (4) recuperativity; (4A) potential time; (5) behaviour as storage cells; (5A) power time or output in watt-hours.

Test 1: Potential Current.—The connections were the same as before. The test was conducted as follows: (1) the E.M.F. of each cell was taken; (2) currents of certain values were obtained from each cell alternately for five minutes; (3) the potential difference and current at the end of each period of five minutes was noted; (4) at the end of each five minutes the current was stopped, and readings taken of E.M.F. every five seconds until it became steady. By plotting the curve backwards, the value of the E.M.F. at the end of the five minutes was ascertained.



SHEET I.

Table II. shows a few of the results (see "Potential Current," Curves 1 and 2 on Sheet I.):

TABLE II.

Current in amperes	Obach A.			E.C.C. No. 1.		
	E.M.F. in volts.	P.D. in volts.	E.M.F. at end of each five minutes.	E.M.F. in volts.	P.D. in volts.	E.M.F. at end of each five minutes.

0·144	1·401	1·368	1·372	1·368	1 320	1·344
0·168	1·392	1·358	1·372	1·359	1 305	1·329
0·192	1·392	1·344	1·368	1·344	1 296	1·320
0·216	1·372	1·344	1·368	—	—	—

Test 2: Internal Resistance as calculated from the results of Test 1, given in Table II. The potential difference at the end of each period of five minutes was deducted from the total E.M.F. at the end of each period. This gives the voltage absorbed inside the cell. Then this internal voltage or fall of potential inside the cell, divided by the current at the time, gives the apparent internal resistance of the cell. The following table shows the results (see Sheet I. for curves):

TABLE III.

E.M.F. absorbed (volts).		Current (amperes).	Resistance of cell (ohms).	
Obach A.	E.C.C. 1.	Obach and E.C.C.	Obach A.	E.C.C. 1.

·004	·024	·144	·027	·166
·014	·024	·168	·083	·142
·024	·024	·192	·125	·125
·024	—	·216	·111	—

Test 3: Total Output.—The cells used in the last test—viz., an Obach A and an E.C.C. No. 1—were connected up with a constant resistance of about 10 ohms. A reading of the E.M.F. was taken at the beginning. Then readings of current and potential difference were taken every 10 minutes for two hours, and less frequently afterwards. Voltameters were also placed in circuit to find the total ampere-hours.

The gain of the Obach's plate = 40·557 grammes.
" " E.C.C.'s " = 35·264 "

Weight of copper deposited in one hour by one ampere = 1·177 grammes, therefore the total number of ampere-hours from
Obach A. ..... = 34·4 ampere-hours.
E.C.C. No. 1 ..... = 29·9 "

Table IV. shows a few of the results (see Sheet II. for curves).

Test 4: Recuperativity.—This test was carried out with the same cells as in the last test—viz., Obach A and E.C.C. No. 1. They were short-circuited for 120 hours, so as to be practically exhausted. The same galvanometer was employed as a voltmeter, and readings of the potential difference were taken every five minutes for an hour, and at longer intervals thereafter. Table VI gives a few of the results* (see Sheet III. for curves):

* Note of Messrs. Siemens Bros. and Co., Limited, London, June 2, 1894.—Referring to Prof. Jamieson's Test 4 on recuperativity, and the corresponding curves on Sheet III., it might seem at first glance that the recuperation of the "E.C.C." cell, shown in the above Table VI. as 1·056 volts, was superior to that of the "Obach" cell, which reached a voltage of only ·782. A closer investigation of this statement, although correct in itself, shows that the "Obach" cell had when this test began an internal resistance of only ·3 ohm, whereas that of the "E.C.C." had already attained more than double that amount—viz., ·62 ohm. The output of current during the short-circuiting for 120 hours must therefore have been considerably greater for the "Obach" cell, by reason of its lower resistance, than in the "E.C.C." cell. In consequence of this, the test of recuperativity showed after 10 minutes a voltage of ·288 for the Obach, and ·576 for the E.C.C., resulting after 24 hours' recuperation in a net increase of ·494 volt in favour of the Obach, and ·480 volt in favour of the E.C.C. This is a result most favourable for the Obach cell, the more so when we consider that it was doubly as much exhausted when the experiment began as its competing E.C.C. cell. According to our own experiments, we are in a position to say that had a longer time been allowed for recovery, say some days, instead of one day only, our cell would invariably reach by recuperation a final E.M.F. of 1·2 to 1·3 volts. This maximum is more rapidly reached by the smaller than by the larger sizes, since it depends almost entirely on the rapidity of permeation of the depolariser by atmospheric oxygen.—Approved by Prof. Jamieson.

SHEET III.

Test 4a: Potential Time.—This is the same as Test 3. Both cells were coupled up through a constant resistance of five ohms, and the fall of voltage was noted for about an hour after the current started.

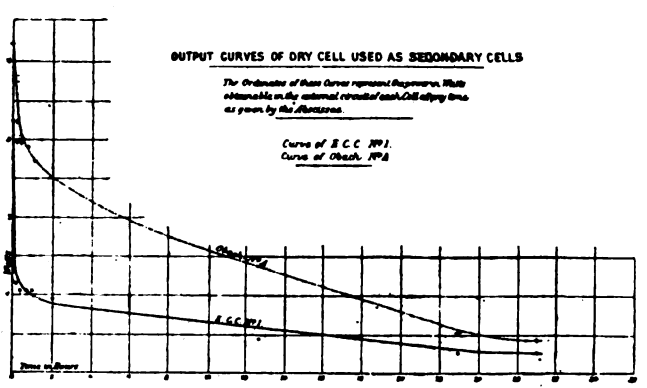
Test 5: Behaviour as Storage Cells.—The above cells were then short-circuited for a considerable time until the voltage had fallen to ·048 volt in the case of the Obach, and ·168 volt in the case of the E.C.C. They were then connected up in series and charged with a current of about two amperes from the storage cells in the laboratory. The current was kept on for seven hours—*i.e.*, until 14 ampere-hours had been given to them. The E.M.F.'s, when disconnected, were: Obach = 1·464 volts; and E.C.C. = 1·296 volts.



SHEET IV.

Test 5a: Power Time.—(See Sheet IV. for curves) The cells were then discharged through a constant resistance of five ohms, and the potential difference was observed every four minutes, as follows in Table VIII. The output in watts was derived from the product of the respective potential differences and their corresponding calculated currents; or from $P.D.^2 \div R$, where R = 5 ohms external resistance.

Remarks.—Since these results have been obtained under exactly the same conditions for each cell, they form a very fair comparison of their general efficiency. They demonstrate in most cases the superiority of the Obach cell. This may be accounted for by its greater weight*, as it is 8oz. heavier than the E.C.C., but it is very little greater in bulk, and is quite as convenient to handle. When a large current is taken, a viscous sort of fluid begins to ooze from the Obach cell.† This may prove troublesome unless it is noticed. It may be said, however, that with the moderate currents used in these tests no trouble was experienced until they were short-circuited, when, of course, the current was only limited by the internal resistance of the cell.

Bell Ringing Test (taken by John Burns, March and April, 1894).—In addition to these tests, two cells (one Obach and one E.C.C.) were tried in order to ascertain which of them would ring an electric bell for the longer time. The two cells were alternately placed in circuit with a trembling bell for six minutes at a time by means of a clock and mercury contacts. Each cell had alternately six minutes' work of ringing the bell and six minutes' rest. After the clock had gone 1,552 hours 30 minutes, the E.C.C. cell failed to ring the bell. It had consequently done 776 hours 15 minutes' work with a corresponding time of rest. The Obach cell continued to ring the same bell, under identically the same conditions, for 1,700 hours 30 minutes from the commencement, or 850 hours 15 minutes' of work, with a corresponding number of hours' rest. Thus the Obach cell rang the bell for 74 hours longer than the E.C.C. cell.

ELECTRICAL STANDARDS.

NEW DENOMINATIONS.

An Order by the Queen in Council specifying and describing the new standards of electrical measurements for use in trade was published in the *London Gazette* last Friday. The Order is as follows:

Whereas by the Weights and Measures Act, 1889, it is among other things enacted that the Board of Trade shall from time to time cause such new denominations of standards for the measurement of electricity as appear to them to be required for use in trade to be made and duly verified.

And whereas it has been made to appear to the Board of Trade that new denominations of standards are required for use in trade based upon the following units of electrical measurement—viz.:

1. The ohm, which has the value 10^9 in terms of the centimetre and the second of time, and is represented by the resistance offered to an unvarying electric current by a column of mercury at the temperature of melting ice 14·4521 grammes in mass of a constant cross-sectional area and of a length of 106·3 centimetres.

2. The ampere, which has the value $\frac{1}{10}$ in terms of the centimetre, the gramme, and the second of time, and which is represented by the unvarying electric current which when passed through a solution of nitrate of silver in water in accordance with the specification appended hereto, and marked A, deposits silver at the rate of 0·001118 of a gramme per second.

3. The volt, which has the value 10^8 in terms of the centimetre, the gramme, and the second of time, being the electrical pressure that if steadily applied to a conductor whose resistance is one ohm will produce a current of one ampere, and which is represented by ·6974 ($\frac{1000}{1434}$) of the electrical pressure at a temperature of

* As regards the somewhat greater weight of our cell in comparison with the E.C.C., this is chiefly due to the use of thicker zinc for our cells. Prof. Jamieson, in his former report, called attention to the circumstance that the E.C.C. zincs were too thin for practical purposes; the heavier zinc is therefore rather an advantage than otherwise.—S. B. and Co.

† With our earlier make of these cells, which were the sort supplied to Prof. Jamieson, a viscous liquid occasionally oozed from the cell; we have, however, since then entirely overcome this defect by some slight alterations in the construction of the cell.—S. B. and Co.

Digitized by Google

15deg. C. between the poles of the voltaic cell known as Clark's cell set up in accordance with the specification appended hereto, and marked B.

And whereas they have caused the said new denominations of standards to be made and duly verified.

Now, therefore, her Majesty, by virtue of the power vested in her by the said Act, by and with the advice of her Privy Council, is pleased to approve the several denominations of standards set forth in the schedule hereto as new denominations of standards for electrical measurement. C. L. PEEL.

SCHEDULE.

I. *Standard of Electrical Resistance.*—A standard of electrical resistance denominated one ohm being the resistance between the copper terminals of the instrument marked "Board of Trade Ohm Standard Verified 1894" to the passage of an unvarying electrical current, when the coil of insulated wire forming part of the aforesaid instrument and connected to the aforesaid terminals is in all parts at a temperature of 15·4 C.

II. *Standard of Electrical Current.*—A standard of electrical current denominated one ampere being the current which is passing in and through the coils of wire forming part of the instrument marked "Board of Trade Ampere Standard Verified 1894," when, on reversing the current in the fixed coils, the change in the forces acting upon the suspended coil in its sighted position is exactly balanced by the force exerted by gravity in Westminster upon the iridio-platinum weight marked A, and forming part of the said instrument.

III. *Standard of Electrical Pressure.*—A standard of electrical pressure denominated one volt being one-hundredth part of the pressure which, when applied between the terminals forming part of the instrument marked "Board of Trade Volt Standard Verified 1894," causes that rotation of the suspended portion of the instrument which is exactly measured by the coincidence of the sighting wire with the image of the fiducial mark A before and after application of the pressure, and with that of the fiducial mark B during the application of the pressure, these images being produced by the suspended mirror and observed by means of the eyepiece.

In the use of the above standards the limits of accuracy attainable are as follows:

For the ohm, within one-hundredth part of 1 per cent.
For the ampere, within one-tenth part of 1 per cent.
For the volt, within one-tenth part of 1 per cent.

The coils and instruments referred to in this schedule are deposited at the Board of Trade Standardising Laboratory, 8, Richmond-terrace, Whitehall, London.

SPECIFICATIONS referred to in the foregoing Order in Council.

SPECIFICATION A.

In the following specification the term silver voltameter means the arrangement of apparatus by means of which an electric current is passed through a solution of nitrate of silver in water. The silver voltameter measures the total electrical quantity which has passed during the time of the experiment, and by noting this time the time average of the current, or if the current has been kept constant the current itself, can be deduced.

In employing the silver voltameter to measure currents of about one ampere the following arrangements should be adopted: The cathode on which the silver is to be deposited should take the form of a platinum bowl not less than 10 centimetres in diameter, and from four to five centimetres in depth.

The anode should be a plate of pure silver some 30 square centimetres in area and two or three millimetres in thickness.

This is supported horizontally in the liquid near the top of the solution by a platinum wire passed through holes in the plate at opposite corners. To prevent the disintegrated silver which is formed on the anode from falling on to the cathode, the anode should be wrapped round with pure filter paper, secured at the back with sealing-wax.

The liquid should consist of a neutral solution of pure silver nitrate, containing about 15 parts by weight of the nitrate to 85 parts of water.

The resistance of the voltameter changes somewhat as the current passes. To prevent these changes having too great an effect on the current, some resistance besides that of the voltameter should be inserted in the circuit. The total metallic resistance of the circuit should not be less than 10 ohms.

Method of Making a Measurement.

The platinum bowl is washed with nitric acid and distilled water, dried by heat, and then left to cool in a desiccator. When thoroughly dry it is weighed carefully.

It is nearly filled with the solution, and connected to the rest of the circuit by being placed on a clean copper support to which a binding screw is attached. This copper support must be insulated.

The anode is then immersed in the solution so as to be well covered by it, and supported in that position; the connections to the rest of the circuit are made.

Contact is made at the key, noting the time of contact. The current is allowed to pass for not less than half-an-hour, and the time at which contact is broken is observed. Care must be taken that the clock used is keeping correct time during this interval.

The solution is now removed from the bowl, and the deposit is washed with distilled water and left to soak for at least six hours. It is then rinsed successively with distilled water and absolute alcohol, and dried in a hot-air bath at a temperature of about 160deg. C. After cooling in a desiccator it is weighed again. The gain in weight gives the silver deposited.

To find the current in amperes, this weight, expressed in grammes, must be divided by the number of seconds during which the current has been passed, and by 0·001118.

The result will be the time average of the current, if during the interval the current has varied.

In determining by this method the constant of an instrument the current should be kept as nearly constant as possible, and the readings of the instrument observed at frequent intervals of time. These observations give a curve from which the reading corresponding to the mean current (time average of the current) can be found. The current, as calculated by the voltameter, corresponds to this reading.

SPECIFICATION B.

ON THE PREPARATION OF THE CLARK CELL.

Definition of the Cell.

The cell consists of zinc or an amalgam of zinc with mercury and of mercury in a neutral saturated solution of zinc sulphate and mercurous sulphate in water, prepared with mercurous sulphate in excess.

Preparation of the Materials.

1. *The Mercury.*—To secure purity it should be first treated with acid in the usual manner, and subsequently distilled *in vacuo*.

2. *The Zinc.*—Take a portion of a rod of pure redistilled zinc, solder to one end a piece of copper wire, clean the whole with glass-paper or a steel burnisher, carefully removing any loose pieces of the zinc. Just before making-up the cell dip the zinc into dilute sulphuric acid, wash with distilled water, and dry with a clean cloth or filter paper.

3. *The Mercurous Sulphate.*—Take mercurous sulphate, purchased as pure, mix with it a small quantity of pure mercury, and wash the whole thoroughly with cold distilled water by agitation in a bottle; drain off the water, and repeat the process at least twice. After the last washing, drain off as much of the water as possible.

4. *The Zinc Sulphate Solution.*—Prepare a neutral saturated solution of pure ("pure recrystalised") zinc sulphate by mixing in a flask distilled water with nearly twice its weight of crystals of pure zinc sulphate, and adding zinc oxide in the proportion of about 2 per cent. by weight of the zinc sulphate crystals to neutralise any free acid. The crystals should be dissolved with the aid of gentle heat, but the temperature to which the solution is raised should not exceed 30deg. C. Mercurous sulphate treated as described in 3 should be added in the proportion of about 12 per cent. by weight of the zinc sulphate crystals to neutralise any free zinc oxide remaining, and the solution filtered, while still warm, into a stock bottle. Crystals should form as it cools.

5. *The Mercurous Sulphate and Zinc Sulphate Paste.*—Mix the washed mercurous sulphate with the zinc sulphate solution, adding sufficient crystals of zinc sulphate from the stock bottle to ensure saturation, and a small quantity of pure mercury. Shake these up well together to form a paste of the consistence of cream. Heat the paste, but not above a temperature of 30deg. C. Keep the paste for an hour at this temperature, agitating it from time to time, then allow it to cool; continue to shake it occasionally while it is cooling. Crystals of zinc sulphate should then be distinctly visible, and should be distributed throughout the mass; if this is not the case, add more crystals from the stock bottle, and repeat the whole process.

This method ensures the formation of a saturated solution of zinc and mercurous sulphates in water.

To set up the Cell.

The cell may conveniently be set up in a small test tube of about two centimetres diameter, and four or five centimetres deep. Place the mercury in the bottom of this tube, filling it to a depth of, say, ·5 centimetre. Cut a cork about ·5 centimetre thick to fit the tube; at one side of the cork bore a hole through which the zinc rod can pass tightly; at the other side bore another hole for the glass tube which covers the platinum wire; at the edge of the cork cut a nick through which the air can pass when the cork is pushed into the tube. Wash the cork thoroughly with warm water, and leave it to soak in water for some hours before use. Pass the zinc rod about one centimetre through the cork.

Contact is made with the mercury by means of a platinum wire about No. 22 gauge. This is protected from contact with the other materials of the cell by being sealed into a glass tube. The ends of the wire project from the ends of the tube; one end forms the terminal, the other end and a portion of the glass tube dip into the mercury.

Clean the glass tube and platinum wire carefully, then heat the exposed end of the platinum red hot, and insert it in the mercury in the test tube, taking care that the whole of the exposed platinum is covered.

Shake up the paste and introduce it without contact with the upper part of the walls of the test tube, filling the tube above the mercury to a depth of rather more than one centimetre.

Then insert the cork and zinc rod, passing the glass tube through the hole prepared for it. Push the cork gently down until its lower surface is nearly in contact with the liquid. The air will thus be nearly all expelled, and the cell should be left in this condition for at least 24 hours before sealing, which should be done as follows.

Melt some marine glue until it is fluid enough to pour by its own weight, and pour it into the test tube above the cork, using sufficient to cover completely the zinc and soldering. The glass tube containing the platinum wire should project some way above the top of the marine glue.

The cell may be sealed in a more permanent manner by coating

Digitized by Google

the marine glue, when it is set, with a solution of sodium silicate, and leaving it to harden.

The cell thus set up may be mounted in any desirable manner. It is convenient to arrange the mounting so that the cell may be immersed in a water-bath up to the level of, say, the upper surface of the cork. Its temperature can then be determined more accurately than is possible when the cell is in air.

In using the cell sudden variations of temperatures should as far as possible be avoided.

The form of the vessel containing the cell may be varied. In the H form, the zinc is replaced by an amalgam of 10 parts by weight of zinc to 90 of mercury. The other materials should be prepared as already described. Contact is made with the amalgam in one leg of the cell, and with the mercury in the other, by means of platinum wires sealed through the glass.

MR. MOLESBY'S MYSTERIOUS MOTOR.

The inauguration of the new electricity works at Garnesdon* was not a huge success, unless viewed in the light of a farce or from the local gas company's point of view. Never, surely, since the days of Eve had a chairman's good lady pressed an inaugurative electric button to such little useful purpose. True it is that certain effects were produced—to wit, irritating smiles on the faces of the guests, anguished disappointment in the hearts of the board of directors and the permanent officials, and wild and weird blasphemy from the lips of the working staff behind the scenes when they heard the "fizz-z-zpit" of the main fuse, realised the unaccountable clogging of a turbine, and became aware of the fact that the exciter in use had developed a short-circuit in its armature windings.

However, the chairman stuck to his guns, and explained that the contractors for the plant had so much delayed its delivery that the staff had had to work day and night on its erection sooner than postpone the date of the inaugural ceremony. This unavoidable haste, he assured his audience, was the cause of the breakdowns, which would never occur in actual work. The explanation was received hopefully by the guests.

The Convivial Gathering.

At the next time of asking the station was successfully illuminated, and the current was in the mains ready for use. Then followed a tour of inspection through the machine-room and an adjournment for dinner at The King's Head, after which toasts and speechmaking of the mutually appreciative order, so necessary to the success of such functions, took place. It was a dinner worthy of the name, and the ladies and other respectable people having departed early, the meeting resolved itself into a committee of ways and means of liquor-judging, and was finally thrown out at closing time. It is sad to record that the old gas lamp-posts having been pulled down and taken away, and the new electric lamps standards being fewer in number and placed very inconveniently in the centre of the roadway, the facilities for reaching home were reduced to a minimum, with direful consequences to the appearance and apparel of the more enthusiastic of the diners whose homeward ways lay through muddy roads.

A few days afterwards the engineer Holloway and the canvasser Barker were talking shop at the electricity works.

"You would hardly credit the amount of harm those breakdowns have done," Barker was saying. "Before the opening I couldn't get applications down fast enough, and now I have to fight for them; and the people who haven't had the wiremen in yet want to back out of their agreements."

"Don't you fret," said Holloway, "when we've run for a few months without anything going wrong, you'll find they'll flock after you again."

"Well, I hope so. I've perjured my soul quite enough with regard to the future infallibility of things here. And worst of all, I find that old Molesby, of Berkley-street, is going to put down a private plant solely on account of the mess made at the opening."

"Private grandmother," sneered Holloway; "why the man won't want 25 lights in the whole show. Wait till he finds out what it will cost him to instal, not to mention work it. Ho! ho! ho!"

"Well, I'll just go round and worry the beggar again. He may have got an estimate in by now which has opened his eyes," and Barker went out with a canvasser's firm belief in the omnipotency of the human tongue. He went straight to Berkley-street and called at the house. "Mr. Molesby was engaged in the coal-cellar," the servant said, "but would Mr. Barker come inside and wait?" So Barker sat down in an easy-chair in the front room and prepared for action. That is to say, he cleared his throat, and ascertained that his necktie had not crawled up the back of his head—which property of disregarding the laws of gravity and respectability is peculiar to neckties, and part of the system of inanimate cussedness which exists to try the patience of and torment human kind in general. Barker thought the coal-cellar a strange place for a man to pass his time in, even after making due allowance for Mr. Molesby's eccentricity, which was as notorious as his grasping meanness. The fact of his going in for such a comparative luxury as the electric light could only be accounted for by reason of the former peculiarity.

A Fruitless Journey.

Presently the object of the visit entered, dressed as the eye of man had probably never before seen him, for he was a neat man notwithstanding his oddness—a disreputable suit of clothes embellished with a boot-blacking apron, and the whole covered with clay, mortar, and dust; and if an unbiassed observer had had to judge of his occupation by the state of his hands, the resulting opinion would have probably been "mudpie-making."

"Good afternoon," said the canvasser, blandly; "I have called from the electric light company to see if you have decided to let us supply you with electric light, the light of the future, Mr. Molesby."

"I'm very sorry you've given yourself that trouble," said Mr Molesby; "but I'm just now engaged upon making ready foundations for my own electric light plant. You did not know, maybe, that I was in the electrical line myself a few years back, and I found out a better way of getting the light than by paying eightpence a unit and risking all manner of breakdowns at your works yonder."

"There'll be no more breakdowns now," Barker explained, "and I hope you know what your plant will cost—boiler, steam-engine——"

"I'm using no engine," interposed Mr. Molesby, quietly.

"Gas-engine, then, I suppose?"

"Nor gas-engine either. It's nothing more nor less than an engine of my own invention, that only needs half an hour's attention a day, and starts itself as soon as a switch is turned on. Now that's all I'm going to tell you till I've perfected the thing, and then you can come to me for your light of the future and I'll let you have it for a penny a unit delivered anywhere. Good afternoon, sir," and Mr. Molesby brusquely disappeared whence he came.

"The man's stark, staring, damp mad," said Barker to himself on his way back to the works. And Holloway, the engineer, said something similar when he heard of this invention which seemed destined to revolutionise electricity supply. They two and Lavington, the electrician, sat down in the nearest chairs, which happened to be at The King's Head, and made exceeding merry over it—which was only right and proper under the circumstances.

The Work of the Motor.

Nevertheless, when in a month's time the Molesby domicile was found to be illuminated throughout by the electric light, their mocking grew less, the more especially when they found that not only had Mr. Molesby wired the house throughout with his own hands, but that nothing of the nature of an ordinary engine could be seen or heard. His chimneys vented forth but an ordinary amount of smoke, and neither knocking nor vibration was perceptible from the outside of the house. Many were the solutions suggested by the three people most interested in the matter—Holloway, the engineer; Barker, the canvasser; and Lavington, the electrician—but none seemed to fill the bill. Holloway pinned his faith on a water motor, and went straightway to the waterworks to investigate, but the officials there declared, after examining into the case on his kindly information, that they were satisfied only an ordinary amount of water was used by the Molesby household. Lavington said it was a windmill concealed upon the roof, which stored up energy by means of springs, accumulators, or compressed air, but a close examination of the roof from a neighbouring house-top did not add strength to that supposition; and Barker's idea, founded upon Mr. Molesby's traditional absence from the bosom of his family during a period of three calendar years, was that he worked a treadmill dynamo for half an hour a day and stored the energy. This, indeed, seemed the only plausible reason, considering the mystery that Mr. Molesby was making of his invention, for the idea that "a broken-down old fakir," as Barker politely expressed himself, was capable of doing anything of a revolutionarily scientific nature was too absurd for anyone's credulity. And as he had distinctly said that it was an engine of some description, primary batteries seemed out of the question. It was very provoking not to be able to get to the bottom of the mystery. Mr. Molesby could be absolutely sphinx-like when he chose, and his putty-faced wife and putty-faced children knew and revered him as the god of their destiny, if not as a husband and father. Without a doubt, if Mr. Molesby had let his family into the secret of the motor, wild horses could not drag it out of them. The rest of the household consisted of the governess and the servant, and all seemed equally inscrutable subjects.

The Three were having a shoppy conversation one night, when the eternal topic of Molesby and his motor came up for discussion. Holloway was a bit mad on the subject at the time.

"The beggar came in here this morning," he exclaimed, "with an infernal cheeky grin on his face, and wanted me to lend him a file to shape his brushes up with—— No, Lavington, I did not tell him to go there—didn't feel rude enough at the time, but I informed him that we never lent our tools out, and what do you think he said then?"

"Well," was the chorus.

"Said he was sorry to find such a lack of professional courtesy in the provinces, and that he was afraid he might not be able to give us help with his machines when ours next broke down. Professional courtesy, eh?"

"Look here," said Lavington; "I don't know how you fellows feel, but I can't stick it any longer. Let's lure the old sinner in here and play Spanish Inquisition on him from the 'bus bars till he tells."

"Won't do," said Holloway. "Not going to make a charnel house of my nice clean station. Any other suggestions? Well, why doesn't Barker get round the governess? Nice girl enough, and trust a woman to find out anything if Barker wanted her to."

"Capital," said that portion of the audience whose name was not Barker. "I second that."

"But how am I to do it?" said Barker, appealingly. "I don't know the girl a bit." There seemed some hidden joke in this, for the Three smiled audibly for some time, and the council ended after the final carrying of the resolution.

The Governess Questioned Without Result.

In the course of a few days the Three met again to report progress. In the interim Barker, in some mysterious way known only to electric light canvassers, had become acquainted with the Molesby governess.

"She says," he continued, after mentioning his success, "that Molesby keeps his machinery, whatever it is, in the cellar; that it came one day in a big box, and that no one in the house, except the ruler thereof, knows anything at all about it. Mr. Molesby keeps the keys to the cellar, which has been fitted with a special lock; has blocked up the pavement grating, and is never seen to take anything in or out. Spends about half an hour daily in there, and never seems fatigued in the least when he emerges. That's all I can get out of the pretty governess."

"We are not much wiser, then," said Holloway; "it seems to bar the treadmill theory, and I suppose she hasn't heard any gearing rattle suggestive of windmills?"

"No; she says everything inside is as quiet as the grave, which makes things more bewildering."

"Can't you induce her to get the keys and go inside and find out?" suggested Lavington, whose valuable advice was usually founded on first thoughts.

"That would be a first-class idea," said Barker, "if old Molesby was not regarded quite so much in the light of an ogre by his household. No, I'm afraid the Bluebeard dodge won't answer. We shall have to wait till he has perfected the thing, if he ever does."

"Wait be hanged!" said Lavington. "I know a plan worth two of that! Let us hire a basement as near as possible to Molesby's cellar and burrow our way into the elucidation." This seemed the only satisfactory plan at the time, but when the actual hiring was attempted the thing fell through, for the very simple reason that nowhere near was there a basement to be had for love or even a reasonable amount of money. There seemed nothing for it but to watch and pray.

A Hauling-in Dodge.

Meanwhile, the successful working of the station had averted the incipient panic among would-be consumers; applications for light flowed in freely again, and a new transformer sub-station became a necessity in the Upper Town. In due course the feeder was drawn into one of the ducts of the Johnstone conduit from the works to the new sub-station, and only in Berkley-street did any hitch occur in the operation. What the hitch was due to no one could at the time make out, but the fact remained that for a long time seven men could not pull through an 80 yards' length of $^{7}/_{18}$'s concentric. There seemed to be an obstacle about half-way between the road boxes that no amount of pulling could overcome, and the foreman of the work went to the central station to get permission to take up the road to find the obstacle. When he came back with the requisite instructions, he found old Molesby critically eyeing the hauling-out rope. Molesby went to meet him in a singularly polite manner and said:

"I see that you are having a difficulty with your cable. Can I, as an old electrician, render you any help with it?"

The foreman, with a certain amount of respect for the man who had invented a new engine, explained that the cable had stuck in the conduit.

"Ah! I often had that trouble when I was in the trade," said Molesby; and there's only one thing to be done when that's the case."

The foreman enquired the remedy.

"If you'll let me direct your men," said Mr. Molesby, "I'll very soon have your cable through."

The foreman was willing, and instructed the men to obey Mr. Molesby, who made them coil up about 10 yards of rope by the road box, and to catch hold each man of the remainder. This done, and a chafing mat put over the edge of the box, Mr. Molesby started the men off at a run. The spare rope between them and the box was soon trailing down the street, and then, instead of the violent jerk or the breaking of the rope that the most optimistic among them expected, the rope gradually tightened, and its regular rate of transit through the box showed that the cable was coming through as it should do, and very soon the length was in place. The foreman expressed his gratitude to Mr. Molesby, who said deprecatively that it was a trick he had learnt in America, and was called "bust the rope or bring the cable," for which information the foreman was truly thankful, and went to examine the cable end, which showed several deep indentations, as if made by ineffectual pulls against the obstacle, whatever it was.

Mr. Molesby had now begun to be regarded as a trade competitor by the electricity company on account of his supplying current in the neighbourhood of his house at the low rental of 5s. per annum per 8-c.p. lamp installed. Most of the houses near him availed themselves of the cheapness, and Molesby had a switchboard fitted up in his back kitchen, from which ran separate cables through the back gardens to his clients' lamps. Never was there such a well-lit block of houses. If Goethe had only died in that block, he would have had to compose different last words. The pity of it was that the lamps were not everlasting, otherwise it would have been quite unnecessary to put up switches at all. And yet Molesby seemed quite happy, explaining to everybody that his motor approached so nearly to perpetual motion as to enable him to do this profitably. When he had made it quite perfect, he said, he would reduce the price to half-a-crown a year. Whereat his fame grew and spread abroad, and at a Board meeting of the G. and D. E. S. Company, Limited, it was seriously proposed to open negotiations with him for the sale of his motor, but when the inventor was approached on the subject he refused to entertain any proposals till the final improvements and patenting had been executed. So the Board said unpleasant things about him.

A Tricky Wireman Arrives on the Scene.

And it came to pass that a wireman in search of work arrived in Garnesdon from America, and business being brisk just then he was engaged as foreman by the firm who had the contract for wiring the Town Hall. This man, Bernard, quickly became acquainted with the staff at the electricity works, and was in great request as a narrator of traveller's tales and moral stories. He, too, became interested in the Molesby motor, but being governed by an unbridled curiosity, and unhampered by a too fastidious conscience, his determination to elucidate the mystery seemed to stand more chance of realisation than was the case with his slightly more scrupulous acquaintances. To this end he booked a seat in a pew just in front of Molesby's, and became a devoted attendant at the little Wesleyan chapel in which Mr. Molesby spent a certain percentage of his wet Sunday mornings. Bernard's idea was that an acquaintanceship formed through a religious body would be more likely to lead to a productive result than an introduction by any other means, and, generally speaking, perhaps he was right. However, after a quarter's trial nothing came of it; the Molesbys kept to themselves in and out of church, and so the time spent by Bernard at services, prayer meetings, and congregational tea fights was only wasted, not to mention the pew rent at 5s. 6d. per quarter.

"However," said Bernard to himself, philosophically, "a good thing takes trouble to get all the world over"; and he was not dismayed, but redoubled his exertions. He took a room as near Mr. Molesby as possible, and prevailed on his landlady to apply for light from the Molesby factory. This she did on finding that she had only to pay the annual price per lamp, the installation being fitted up by Mr. Molesby personally on an easily removable system, so that, as he explained, he might take away the fittings if ever the light was required to be discontinued. The backyards of that block were quite picturesquely festooned with cables to the different customers, and the electricity company felt acutely over the matter, and wrote distracted letters to the Board of Trade, who, however, could do nothing while the cables were on private property. During the installation of Bernard's lodgings he did his best to ingratiate himself with Mr. Molesby, who, unfortunately, evinced a decided distate for him, the more especially when he discovered his calling; and the wiring was finally completed without any advance in Bernard's object—in fact, retrogression—as Molesby seemed perfectly aware that Bernard had an ulterior object to his friendly advances.

Testing His Suspicions.

When the light was switched on Bernard unlaid the strands of his lamp leads and placed a galvanometer between them, the absence of a pronounced deflection showing that the current was of an alternating character. This seemed strange, as for the

Digitized by Google

compact area which Mr. Molesby supplied a continuous current would have been so much more efficient. A faint suspicion dawned upon Bernard, which seemed rather improbable, but which nevertheless stuck in his mind.

The Three had not worried much over the motor subject since the ineffectual transaction with the Molesby governess, but curiosity still mixed with professional jealousy in their breasts, and when the next day Bernard came into the station and began the conversation with a reference to Mr. Molesby, their tongues wagged as vigorously on the subject as of yore, and the old conjectures were again brought under view to seek to explain the mystery. Conversation eventually turned to general subjects, and Bernard took it upon himself to criticise the sub-station transformer method that was in use at Garnesdon.

"And if you really had to feed those things up with coal, as every other less fortunately situated works has to do, you would soon find," he concluded, "what it costs to provide for the maximum load with only one transformer, instead of banking some or regulating the windings."

Holloway confessed, in reply, that there was a huge difference between the output as recorded at the station and the actual commercial output as evidenced by the consumers' meters; that the mains had been tested and found of reasonable insulation resistance, and therefore there seemed nothing to do but to put the blame on to the transformer.

Bernard suggested that the iron conduit might have something to do with the deficiency, by exerting a choking effect upon the current; but Holloway explained that as the positive and negative mains were always placed in the same ducts, the loss from that cause must be too minute to thoroughly explain the difference. Then the conversation turned to the doings of the local cricket club, at which Bernard scoffed and made mockery.

"Cricket, fishing, and going to sleep," he said scornfully. "If you want an exciting game, a game to make your toe-nails arise and stand on end, you must go to a baseball match in the States. No flies on them there! Every man with both feet on springs, and the crowd—my aunt, don't they whisper when a base is stolen?"

"It's much the same kind of thing at a representative cricket match," said Barker, patriotically.

"Much the same! Wait till you've seen the wicket-keeper padded and armoured and masked from head to feet; wait till you've had the top of your head screamed off by the johnnie behind you, then you may begin to say the game's exciting; but that only begins the fun in baseball. Bah! eleven men lounge around a five-acre field and two men take it in turn to let the ball hit their bats occasionally; that's your high-class cricket."

A Manœuvre at the Station.

So it ended with Bernard getting slung out of the station for high treason and blasphemy, and he went home meditating on the link in his chain of evidence which the abnormal transformer loss furnished. "Now, I only want one more proof, and then, Mr. Molesby, we shall begin to take an interest in each other, and my friends of the electricity company may become a little more polite." He thought the matter over during the next day or two, when one evening the plan matured. He charged his landlady to watch the electric light in her sitting-room during his absence, and she being of a rare and obliging variety sat down with her knitting and promised not to fall asleep till he came back. Then he went off to the electricity station with a fell purpose in his mind.

"Hullo! what's brought you here?" politely asked the engineer. "Rather expected you would be dreaming of baseball matches by now."

"Oh, I got sick of reading at home, and I just looked in to see if you had had any breakdowns lately. I haven't felt at all well the last day or two."

"Poor beggar, did the chucking out affect his nerves, or is he sighing for his beloved roast peanuts and iced drinks?" queried Lavington.

"Not much; beer is good enough for me. How filthy hot this place is. Open the door for goodness' sake," and as his friends moved away towards the door Bernard fell forward, clutching one of the switches *en route* to the ground, and the switch being of the knife order opened and let him down to the ground with a jerk. Instantly Holloway rushed to the switchboard and replaced it, watching the voltmeter attached anxiously the while. Lavington had more humanely gone to the assistance of the prostrate Bernard, whom he found in a perfectly rigid condition, features contracted, and a froth at the mouth. He turned him over and unfastened his collar, which proceeding apparently relieved the sufferer, whose breathing grew less stertorious.

"Rummy go, this," observed Lavington; "didn't know the beggar was subject to fits. What had we better do?"

"Oh, sling a bucket of water over him," said Holloway, in not the sweetest of tempers, after the treatment of his beloved machinery.

"Well, old chap," said Lavington, soothingly, "feel better?"

Bernard heaved a sigh of great volume and intensity, and struggled gamely to open his eyes.

"Have a glass of whisky?" suggested Holloway, who was of an intensely practical nature.

The patient feebly nodded his head in the vertical plane of approval, and straightway a glass of neat spirits was put in front of him, which appeared to have the desired effect. "It's very kind of you fellows to look after me like this," he muttered; "I thought I had left those attacks in America. Haven't had one for years."

"Well, when you are going to have another one," said Holloway, who half relented his brutality, "kindly keep away from our switchboard. You opened No. 3 transformer at nearly full load, and the Lord only knows what the customers will say about it to-morrow."

Proof of the Swindle.

Bernard expressed his sorrow for the accident, and asked for a cab to be sent for to take him home. He entered the vehicle like a partially resuscitated corpse, but the ride evidently did him good, for he was a very different being when he alighted, and, after paying the jarvey, hurried into the house to his landlady's sitting-room.

"How's the light been, Mrs. Vernon?"

"It went very dull a short time ago, and I thought it was going out; but it has been just as usual otherwise. However did you think it might go dim to-day. It never does so usually."

"Ah!" said Bernard, knowingly, "I saw Mr. Molesby very tight this morning, and I thought something would happen. I'll just go round to him and give him a piece of my mind. We pay for light, not flashes—eh, Mrs. Vernon?"

It was a delightful walk to the Molesby's—at least, under the circumstances; and all traces of the fit had vanished. Bernard's frame of mind was as it should be with a man when he elucidates a mystery that has puzzled wiser men than he, and doubly so when there is money to be had from the elucidation. For above all things Bernard was practically minded; to him honour and fame were good and to be sought for, but he recognised that while they pandered only to the immediate vanity of the soul, they were even as serviettes and menu cards to a starving man without the golden aid that sustains life and give pleasure to the grosser flesh. So he strolled along gaily, making mental calculations as to how much his discovery was worth intrinsically.

Bearding the Lion.

Mr. Molesby was in, and seemed considerably astonished to see who his visitor was. His face paled visibly when Bernard asked for 10 minutes' private converse with him, but he led the way to his smoke-room, and, without offering a chair, waited frowningly while Bernard inspected the room as if fearful of eavesdroppers.

"Mr. Molesby," said Bernard, impressively, helping himself to a chair, "I have long suspected your electric engine to be an erring miracle, and to-day I had the pleasure of discovering what it really consists of. That being the case, I am hardly sure if it is not my duty to inform the electric light company as to its mode of construction. Can you give me any reason why I should not do so at once?"

Mr. Molesby's face had been slowly growing longer till, discovering his jaw to be reposing on his necktie, he regained his composure with a visible muscular effort, and retorted, angrily: "I don't in the least understand what you mean. Leave my house at once!"

Bernard smiled the smile of he who bluffeth on jacks and queens, and stepped towards the door. "I'll go," he said; "but I shall be back in a few minutes with some of the central-station people, and——" pausing and whispering, "with a pick and shovel."

He was already through the door when Mr. Molesby called him back. "Wait a minute," he exclaimed; "just sit down again and tell me what you mean." Bernard glanced back. Mr. Molesby's eyes were very widely opened and his expression lividly entreating; so Bernard returned, flung himself on to the sofa, and meditated.

"Well!" said Mr. Molesby, a trifle impatiently."

"I think you know what I mean," said Bernard, slowly; "your new motor is all rot, and the current you are selling to the neighbourhood is obtained from the mains that run past your house. Do you want it any plainer than that, or shall I prove my theory?"

Mr. Molesby was quite collected by now; a quickly-realised calamity is painless to some people, and it seemed then that strong measures would not answer with Bernard. "And supposing this be true," he said, "what does it matter to you? Don't you get your light cheaper than if the company supplied it?"

"Very much so; but the point is that I am the only person that knows your secret, and if you care to make it worth my while it can go no farther. If you don't, why I should think the electricity people would be very generous to anyone who could give them a clue to the loss on their mains."

Digitized by Google

"Oh, so they have noticed a loss," said Mr. Molesby, coolly; "I didn't think they would bother about taking measurements when they get their power from turbines. Well, now," he continued, in a much more genial tone, "will you please tell me how you discovered my little secret."

Bernard was nothing loth. "You see," he remarked, "I used to be mains superintendent to an American company, who laid the same kind of conduit they use here. Well, the thing is easily taken to pieces, as you know, and one day a man's house was found to be illuminated whose name was not down on the company's books, and as he didn't have sense enough to brag about a wonderful engine, and light up half the town with it, the company got suspicious, had the pavement up in front of his house, and, sure enough, there were the service wires running into his basements, just as yours are at this moment. And to think that I was ever tenderfoot enough to swallow your motor yarn after that experience! Thinking of that the other day gave me my first clue, and afterwards it was enough to substantiate the thing. Weren't you nervous about being found out? Heavy imprisonment, I should say!"

The Lion Springs.

"Oh, I reckoned that up before I took the risk on," said Mr. Molesby. "I don't see how the law can touch me, except for damage to conduit and cable, since electricity has no visible existence, and beyond that I have been careful to put my own wires into the houses in quite a temporary fashion, so that if the company did find out, I fancy they would prefer to come to an arrangement with me to leave the fittings in and supply my customers than to prosecute, in which case my fittings would come out quick, and few of my present clients would care to go to the expense of rewiring. And, you know, whatever the efficiency of their mains is at present, it matters little with their turbines whether they run at full, half, or quarter load, so that they are not really losing anything. Do you see, Mr. Christopher Columbus?"

"I see," said Bernard. "And now about my little remuneration?"

"What do you want?"

"Half shares."

"You can go straight to the devil or to the company when you like," said Mr. Molesby, sweetly, "but you won't get a penny out of me; and as my household has seen you here it might pan out to a pretty clear case of attempted blackmail, and you wouldn't get much out of the company then."

Bernard was thunderstruck. Truly, Molesby had the pluck of the cornered rat as well as the wisdom of the fox.

A Dishonest Partnership.

With a slight smile at Bernard's blank expression, Mr. Molesby continued: "But I'll tell you what I'll do. I'll make you a present of one of my motors, and you can go into another part of the town and start a branch business."

Bernard did not know whether to laugh at this proposal, to look blue, or to become savage. Therefore he said, "Well, I'm blowed," in a tone of deep conviction.

"I have been thinking of making extensions," Mr. Molesby went on, but could trust nobody to help me, and now that a bountiful Providence has sent you to my aid I think I can see my way clear. There's a little tumbledown cottage we could rent in Church-road, and do even a better business with than I am doing here. Now, come; you would have your house rent free, and nothing to do but spend half an hour a day in a snug little cellar to satisfy a curious world that there is really something in the place, and I'll give you 75 per cent. of the profits."

Bernard thought it over. It seemed easy enough; it was an experience that did not come across one every day, and would be a good tale to recount in after life. The risk was as much to Mr. Molesby as to himself, and Molesby was not the kind of man wilfully to put his precious skin in danger, added to which it seemed the only way by which anything might be made out of his discovery, so Bernard decided to accept the offer and risk.

"What do you reckon I should make over the swindle?" he enquired first.

"If I guarantee you £100 a year, paid quarterly, will that suit you?" queried Molesby.

"I am with you on those terms," said Bernard, and then the ice fairly broken they sat down to make a night of it, and to drink success to the Molesby motor.

It was a very pleasant evening. Bernard related the awakening of his suspicions after testing the lamp leads, and how the discussion at the electricity station on the loss in the mains added to their probability, which suspicions were finally confirmed on finding that the light flickered at his lodgings at the time when he opened the transformer switch at the electricity company's station. Mr. Molesby, however, was apprehensive lest any of his customers had compared notes with the company's customers concerning the flicker, in which case the motor theory would receive a rude shock.

Then Mr. Molesby recounted on his side the invention of his motor; how the inventive idea originated by watching the laying of the conduit, and observing how easily the cable inside could be reached by knocking the wedges out. How, when the work of laying was completed, he excavated the roof of his cellar till he came to the conduit, when, after taking the bottom length off, the service connections to the low-tension cables was an easy job during the period of light load. Then he successfully lit his house, and finding his motor tale gaining credence he proceeded further into the business and lit his neighbours' houses at the expense of the electricity company, and to his own monetary advantage.

This recital of ascendant villainy, and perhaps Molesby's '93 vintage, inflamed Bernard's longing to be in the swim and to taste the joys of unholy success.

"And only once have I been anywhere near discovery," continued Mr. Molesby, triumphantly, "and that was when the company started their extensions and commenced drawing in a new feeder past this house. Of course the thing stuck when it came to the yawning cavity over my cellar, and I believe they would have had the street up if I had been 10 minutes later. As it was I saw the crowd of men by the corner road box just in time to go down to the cellar, clear the cable, and rush out to the gang and show them an 'American' way of drawing cable through a tight place, which of course was only an excuse to get them to give another pull. A most obliging foreman it was; another man would have told me to go to blazes."

It was getting late, so after a few parting drinks, and final arrangements about their new partnership, the precious twain parted.

During the following morning both Holloway and Lavington dropped in at the Town Hall to enquire after Bernard's health. Bernard felt small compunction in seeing them, being naturally highly gifted with hypocrisy. A less highly-gifted man might have been inconvenienced in the conscience department, but Bernard prided himself upon being broad minded, therefore his moral nature was flexible and capable of standing worse strains than this.

Advancing the Swindle.

At the end of the week operations commenced at the new house. Mr. Molesby had been to London in the interim and arranged for a new switchboard to be sent down, together with the requisite cable and switches, all enclosed in a box to be marked "Machinery—With Care." Thus on its delivery it got about the neighbourhood that a new Molesby motor was going to begin operations, and he had small difficulty in persuading people in the vicinity to take the light at the Molesby tariff.

So far Bernard had shrunk from letting his intimacy with Mr. Molesby be known. He wished to put off the day upon which he felt sure he should lose the esteem of his friends at the electricity works, and though he guessed he should gain their envy, as well as the admiration of others who would not be in trade rivalry with him, yet he preferred the facts of the new partnership to become public property at the last possible moment.

It had been arranged that Bernard should make the connections necessary to the successful working of the "motor" at the dead of night, when fewest lights would be on. Mr. Molesby had been working away at the "foundations" arrayed in his boot-blacking apron and disreputable clothes, and one morning Bernard got a note from him saying that all was prepared, and arranging for the final connections that same night. Bernard got his jointer's tools ready, and about midnight went to the house. Mr. Molesby let him in gently, and they both went downstairs as if the house was full of detectives. Arrived in the cellar, Bernard saw that the roof had been torn away for several feet before the conduit had been located at the extreme end of the cellar, and there it hung suspended, black and mysterious.

The two men took their coats off and proceeded to knock out the necessary wedges at the ends of the bottom half, and then, putty only holding the framework together, the piece was soon dislodged and lowered to the ground, exposing five cables.

"Now," said Mr. Molesby, mopping his face with a none too clean handkerchief, "the two cables in the duct nearest the house are the distributors, the ones on the other side nearest the road are the arc light cables, and the middle one is the feeder. Don't touch either of the latter more than you can help—the best of rubber is not more than human; and would you like any gloves to do the jointing?"

The Mysterious Motor Jibs.

"No, thanks," said Bernard; "there'll be no current worth mentioning till morning." And, pulling the meat-safe forward to act as a platform, he commenced hacking away at the insulation with his stripping tool. "These are blooming little cables," he continued; "I shouldn't think the authorities calculated on getting much custom out of this neighbourhood."

"Ah! we'll show them," said Mr. Molesby, exultantly, holding the lamp near the better to compare the cables. "Why, the arc cables are bigger than them."

Bernard gave a violent wrench with his tool, when suddenly

Digitized by Google

there was a spark, a gasping yell, and he fell back against Mr. Molesby and the lamp, knocking the latter to the ground and descending upon its flaming fragments with a crash. Mr. Molesby jumped back astounded, and before he could recover his self-possession, Bernard's body was enveloped in flames, upon which he gazed helplessly for some little time. Then the stench of the burning clothing and a still more ghastly perfume drove him into a more humane frame of mind, and he rushed into the kitchen and proceeded to fill a bucket of water at the tap. This operation took quite a minute and a half, which seemed little shorter than three weeks to Mr. Molesby, who was tormented by a feeling of utter helplessness.

During the waiting interval the events of Mr. Molesby's none too virtuous life forced themselves upon him, and the smell of sizzling flesh was borne in unto his nostrils and did not assist his mind to calmness or coherency. At last the bucket was full, and, strong with the desire to help his friend, Mr. Molesby hurried into the cellar and poured the water upon a smouldering heap that had once been a human body, causing a dense smoke, the odour of which exceeded in subtlety the odour of merely burnt clothes by many degrees. Then, his duty to his partner accomplished, Mr. Molesby sat down to consider affairs.

Plainly this was a case for a clear head. Mr. Molesby's mind grasped the superficial facts that a death had occurred by burning, the result of falling on the top of a smashed lamp, and it certainly seemed strange to him that the fall should have been so heavy as to obliviate the agony of the flames, but beyond that he could only see that what had happened would destroy his business if ever the facts became known, and would also put him in a very suspicious position. Then, since Bernard had given him to understand that no one knew of his partnership, or of his intention to visit the house, the most obvious course of common-sense procedure seemed to him to be to get all traces of the occurrence removed as quickly as possible, and trust to luck, as was his custom, to protect the innocent.

And Kills Both Partners.

That being decided upon, and the spade and pick being handy from the "foundation" work, Mr. Molesby opened the back windows and proceeded to dig a grave in the cellar, which grave he mentally decided should be deep enough to prevent any traces of the incident from becoming known accidentally. It was hard work, and the harder since he had to work silently in the confined space of the cellar. At last he could stoop no longer, and crawled out of the hole to the cooler and less effluvient kitchen.

"Phew!" he muttered, as he blew his nose lustily; "I must get old Cherry Blossom out of smelling reach before morning."

But he could not sit still long, he was too excited to rest utterly, and his back was feeling too brokeny to resume his labours in the grave, so he took his candle back again, and standing on the meat-safe, commenced cutting away at the insulation where the late Bernard had left off, intensely anxious that the job should be finished and all traces removed before the morning. Then another strange thing occurred. A tiny spark between the cable and the knife, a veiled scream, and with a thud Mr. Molesby fell upon what remained of his partner's physical self. And that was all that happened in the cellar that night.

The next day it began to be wondered where the foreman of the Town Hall wiring job was; Mr. Molesby's wife also grew anxious concerning her lord. However, the mystery was cleared up before night. The open windows at the back of the fateful house, and a certain pungent odour, rousing the curiosity of a neighbouring household, the police were communicated with, and then a discovery was made that supplied even Garnesdon with gossip for many months after. The facts soon got round to the electrical works, and an official order to examine Mr. Molesby's premises resulted in the complete elucidation of the motor mystery.

To the Benefit of the Supply Company.

At the inquest, it transpired that the deceased had evidently mistaken the arc light circuit for the distribution mains, and this mistake arose from the fact that in that particular street the arc lamps were suspended from wall brackets, instead of from posts in the roadway, and so the arc cables were placed in the ducts nearest the houses, which special arrangement was, of course, beyond Mr. Molesby's knowledge.

Among the people who mourned Mr. Molesby's death were his customers, who were threatened with disconnection from the "motor" if they did not care to pay the company's charges, and Mrs. Molesby was advised by her lawyer to make a claim for the fittings belonging to her late husband in their houses. But the result of these claims only served to prove the contention that people once having used electric light would be very loth to part with it, and before the end of the year the Garnesdon and District Electricity Supply Company, Limited, had reason to bless the misguided genius of Mr. Molesby for being the means of adding to their load diagram, and eventually to their dividends, by means of his once-time mysterious motor.

ELECTRIC LIGHTING AT ABERGAVENNY.

The report has been issued by Mr. E Manville on the introduction of the electric light into Abergavenny, he having been engaged to advise the Commissioners on the subject. He is of opinion that the undertaking would prove profitable, and in support of that opinion refers to the success which has attended similar undertakings in the hands of certain large municipalities, which he mentions, and makes special allusion to Bradford. He advises that 8d. per unit should be charged at first, and points out that, judging from past experience, the Commissioners will be at no risk of making a loss prejudicial to the gas undertaking should they decide on the erection of an electricity supply station in conjunction with it.

The course to be taken in applying for a license or provisional order is then described, and the report continues: "In your case the first or whole area will be the town of Abergavenny, and for the second area, or compulsory streets, I would advise that you put forward the following: Brecon-road, Frogmore-street, High-street, Cross-street to the Swan Hotel, and Lion-street. Before dealing with the cost of carrying out the scheme I am putting before you, I would wish to describe the systems that are generally in use for the distribution of electrical energy. There are, generally speaking, three systems at present in use by which electricity may be distributed from a generating station to those spots where the energy will be utilised by consumers: first, the high-tension alternating-current transformer system; second, the high-tension continuous-current transformer system; third, the low-tension continuous-current direct system. Each of these systems has its own particular advantages under given circumstances, and each of them is better adapted for particular localities according to the particular characteristics of the particular districts to be served, and each of these three systems may again be modified to make them more particularly suitable for a given locality. The third, or low-tension continuous current direct system, is best adapted for districts in which the lighting is likely to be very concentrated, in which there are no gaps between the streets where electricity would be required, and in which the furthest distance the supply will be required to extend from the distributing point is not likely to be very great. This system is also well adapted for a supply of electrical energy for motive power purposes. I think you will see clearly that this latter system—the low-tension continuous-current direct system—is the one best adapted for supplying the demand in Abergavenny. From a distribution point near the Town Hall, the main street in which the supply mains would first be laid extends only slightly over a quarter of a mile on each side of this point, and the streets off the main street also extend to but a short distance from the distribution point, and even these streets still further afield are no great distance from the same point, and I am of opinion that the demand for electric light that might ever exist in Abergavenny can be best met by the adoption of this system.

"I now come to an important subject in connection with the scheme—viz., the method by which the power for generating the electricity should be produced. It was pointed out to me by some of your committee that there were various streams of water in the neighbourhood from which they thought sufficient power might be obtained. I examined these streams, and I feel sure that none of them are of sufficient size, or have a sufficiently certain supply of water, to make them suitable for the economical production of the power required, this being in the first instance, in the scheme I am laying before you, from 75 to 100 effective horse-power. The choice, therefore, falls between the use of coal, of gas as at present supplied in the town, or water gas; and I am of opinion that water gas will be the most suitable method of producing this power. A steam-engine plant would require separate attendance, which would not allow of its being worked as economically as gas might be produced. The gas production for the town being already overloaded, it would not be possible to produce further for use in gas-engines from this source.

"The gas generating plant would be best situated at the gas-works and the generating station at the Baker-street site. On the basis that if you carry this project into effect you will decide in favour of so locating the plant, the following is a description of the machinery included in the following estimates. At the gasworks will be placed a Dowson generator, producing water gas with anthracite coal. The gas from this generator will be contained in a gasholder capable of holding 10,000 cubic feet, and the generator will be sufficiently large to produce all the gas required by one of the gas-engines when developing its full power of 100 h.p., requiring only the addition of a small steam jet from the existing boiler at the gasworks. It is my proposition that during the times of heavy load—*i.e.*, in the winter from four o'clock in the afternoon to, say, nine at night—that the gas generator should be kept at full work, thus supplying all the gas required without drawing upon the 10,000 cubic feet contained by the gasholder. For the remainder of the evening, from nine to 12 o'clock, when the load on the gas-engine will have very much decreased, the gas generator can be stopped altogether, and the gas contained in the gasholder will contain a sufficient supply to run the gas-engine for this length of time. From midnight until four o'clock the following afternoon the gas-engines will not be run at all, the set of electric accumulators provided for in the hereafter appended estimates being sufficient to maintain the 35 public lamps during the remainder of the night, and any small demand there may be for private lamps during that time or during the following day. In the summer the same cycle of operations will be observed, excepting that as the heavy load time will be much shorter than in the winter, the gas

Digitized by Google

generator will be at work for a shorter proportion of time. When the demand for electric light increases so that it is found desirable to put down a third gas-engine, when two would be working at maximum power through the hours of heavy load, it will only be necessary to add the second gas generator at the gasworks with its subsidiary apparatus. From the gasholder to the generating station in Baker-street will be laid a 9in. cast-iron gas-main. The generating station in Baker-street will consist of an oblong brick building, say, 40ft. by 80ft. In this generating station will be placed, in the first instance, two gas-engines, each capable of indicating 100 h.p., and two electric generators of the same size. Only one gas-engine and one generator will be required for the maximum number of lamps provided for in the estimates hereafter appended, the other being completely spare; and when a third gas-engine and generator is added on the extension of the system, there will still be only one set completely spare, whilst the output of the station will be double. In the generating station will also be provided a set of accumulators of sufficient size to run the 35 public lamps from the time that the gas-engines are stopped until dawn, and to supply any likely demand for private lighting during this time and during the hours of daylight." The report then gives in detail an estimate of the cost of outlay, maintenance, and revenue. The cost of providing plant is estimated at £8,168. 17s. 6d.; the annual revenue is estimated at £1,105, and the cost of working and maintenance at £871. 8s., leaving an annual profit of £233. 12s. This would provide for 2,000 8-c.p. lamps at 8d. per unit, and 35 public lamps at £3 each, and allow £400 for depreciation."

ELECTRIC LIGHTING AT MONMOUTH.

In our last issue we referred to the adoption by the Monmouth Town Council of the combined scheme prepared by Messrs. Bramwell and Harris for electric lighting and sewage disposal at Monmouth. A few extracts from the report presented by Messrs. Bramwell and Harris will be of interest:

The carrying out of the sewage scheme alone will involve an original expenditure of £12,000, and will involve an annual expenditure equal to a rate of 1s. in the £ sterling, and we propose now to consider whether the addition of a scheme for the supply of electrical energy, if carried out on the lines of utilising the water power at the Old Forge Mill, will enable you in the near future, when the whole product of the electric generating station is absorbed, to reduce the amount of the rate from the 1s.; or, to put it another way, whether the receipts to be derived from the sale of electrical energy will not be so much that when they are set against the annual expenditure, including every item for the two combined schemes, they will reduce the £900 per annum (which is the cost of working the sewage scheme alone), and will thereby reduce the 1s. rate.

Having heard the result of private enquiries, and having ourselves made enquiries, so far as it was possible, we are of opinion that, providing it could be done at a reasonable cost, your Council would be perfectly justified in establishing a station capable of supplying at one time current for 1,000 lamps each of 16 c.p. installed, or, stated in the general way in which electric light is now estimated, 2,000 lamps of 8 c.p. each installed. More especially would this be true if there were included in this amount of light, the light necessary for street-lighting, replacing therefore the existing gas lamps by the superior electric light, and crediting the revenue of the electric light station with the present annual cost of the gas lamps.

Under the above circumstances we have examined the district with the object of ascertaining whether it was possible to, in any way, utilise some of the large amount of power running to waste in the rivers passing through your town. Practically, the only suitable place which is available for obtaining water power in or near the centre of the town is the present disused Old Forge Mill on the Osbaston-road. We have already pointed out that this is close to both the suggested sites for the sewage disposal. We are informed, as the result of enquiries that have been made, that the owner of the property is prepared to lease the water power here to the Corporation, and also to lease sufficient land for the erection of an electric generating station. There is ample water power for a reasonably large station, larger than it is probable you will require for a considerable number of years to come. To utilise some of this water power we should propose to place at the Old Forge Mill three turbines, each being capable of giving, say, 35 i.h.p. These together, when working at their maximum, would generate electrical energy sufficient for, say, 1,700 8-c.p. lamps, or their equivalent, alight at one time, equal therefore to something like 2,500 8-c.p. lamps installed. We should suggest that there should be four alternating-current dynamos (one being stand-by), each capable of absorbing the power developed by one turbine; there should also be three steam-engines, each of similar power to the turbines, and the machinery should be so arranged that either the turbines or the steam-engines, or both, should be capable of driving three alternating-current dynamos working to a pressure of 2,500 volts. From this station we would lay (so far as is possible in the same trench as the pumping main for the sewage) an electric light and power main to the sewage pumping station, would there connect it to three alternating-current motors, one for each set of pumps, to be used for pumping the sewage. In the sewage pumping station the high-tension current, brought there by this electric main, would be transformed to low-tension current of 100 volts pressure, and from the transformers to be placed in this station, and in, say, two other suitable places, the electrical energy would be carried by distributing mains to every part of the town where demand for current arises. From this distributing main the street lights would also be lit. The attendant in the sewage station would control the lighting by means of the transformers and apparatus placed in that station, and would also superintend the working of the sewage pumps and of the water pump hereafter referred to.

Our estimate of the first cost of this work, allowing a small sum for the purchase of the land for the sewage and electricity transformer station, amount to £5,600. We estimate the annual cost of working this installation, allowing a sum of £50 per annum as rental for the land and water power at the Old Forge Mill, and allowing for every other possible item, including repayment of capital and interest on loan, at 5 per cent. on the cost, all as in the sewage scheme, at the sum of £700 per annum. There is a further source of income which has been suggested, by which we think your Council ought to benefit, and that is the present cost of pumping the water for the cattle market and for flushing sewers, etc. This work could easily be done by the attendants at the sewage pumping station, which is close to the river—the water being taken from the river. The cost of the machinery for doing this, driven either electrically or by a gas engine, would be extremely small, and is included in our estimates.

Experience shows that from each 8-c.p. lamp installed a revenue is derived equal to, say, 7s. per annum. In many cases this is exceeded, but the average receipt of 7s. per annum per 8 c.p. lamp may be assumed to be accurate for the purpose of this report. At this rate, when 2,500 lamps, each of 8 c.p., or their equivalent, are installed, a gross revenue will be derived from the electrical generating station of £875 per annum. To this may be added the sum of £50 a year to be saved from the pumping of water for use in the cattle market, and for use in flushing the sewers; and in considering the combined schemes there should also be added the cost of pumping the sewage, because this will form a revenue for the electric generating station, we estimate this cost as £150 per annum. The total annual income to be derived from the combined schemes therefore appears to be £1,075. The working cost of the schemes amount, as already stated, for the sewage scheme to £900 per annum, and for the electric lighting scheme to £700 per annum, deducting the £1,075 of income to be derived from the combined schemes, there is a balance left of £525 per annum, which will have to be found from the rates. This would involve a rate equal to, say, 7d. in the £, or, in other words, your Corporation would, by expending the larger sum of, say, £17,600 for the combined schemes, be able to carry out, and to carry on, the whole of the work with a rate of 7d. in the £ sterling, instead of a rate of 1s. in the £ sterling, which would be required if the sewage scheme alone, costing £12,000, is carried out. The above is based upon an estimated output from the electric generating station equal to 2,500 lamps of 8 c.p. each installed. When this output is exceeded the income will be correspondingly increased, while there will be but less proportionate increase in the expenditure—that is to say, the suggested rate of 7d. in the £ sterling will be still further reduced.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Widnes.—The Corporation desire by September 4 tenders for the supply of a steel Lancashire boiler. Specifications and other particulars may be obtained from Mr. Isaac Carr, A.M.I.C E., Gasworks, Widnes. Tenders are to be delivered to Mr. H. S. Oppenheim, town clerk, Town Hall, Widnes.

Cheltenham.—The Corporation invite tenders by September 8 for junction-boxes, covers, and other castings. Specifications, forms, and conditions of tender may be had on application to the borough surveyor, Municipal Offices, Cheltenham. Tenders to be sent in to Mr. E. T. Brydges, town clerk, Municipal Offices, Cheltenham.

West Bridgford (Notts.).—The Local Board require by September 3 tenders for supplying and fixing a new boiler at the pumping station, West Bridgford. Particulars can be obtained on application to the Board's surveyor, Mr. T. C. Gray, Stratford-road, West Bridgford. Tenders are to be sent to Mr. Arthur T. Ashwell, clerk, St. Peter's Church-walk, Nottingham.

Edinburgh.—The Corporation invite tenders for the following work in connection with the electric lighting of the city: Contract No. 18.—supply of arc lamp-posts. Copies of the specification and drawings can be obtained from the Resident Electrical Engineer, Dewar place, Edinburgh. Complete full-size detail drawings can be inspected, and all information will be supplied at the office of the Consulting Electrical Engineer, 14, Old Queen-street, Westminster, S.W.. or at the office of the Resident Electrical Engineer, Dewar-place, Edinburgh. Copies of the specification may be obtained on sending a deposit of £1. 1s. Tenders are to be directed to Mr. Wm. Skinner, W.S., town clerk, by September 17.

RESULTS OF TENDERS.

Southampton—The Harbour Board have accepted the tender of Messrs. Crompton and Co., at £789, for the electric lighting of the Town Quay.

Edinburgh.—The Electric Lighting Sub-Committee of the Edinburgh Town Council have accepted tenders of Messrs. Ferranti, Limited, for steam-engines, alternators, switchboard,

Digitized by Google

and rectifiers, and of the India Rubber, Gutta Percha, and Telegraph Works for insulated cable, amounting to between £4,000 and £5,000.

BUSINESS NOTES.

Dunblane.—The Police Commission will apply for a provisional order themselves.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,545.

Denbigh.—The Town Council are investigating methods of lighting the town by electricity.

Plant for Sale.—Our advertisement columns contain particulars of various kinds of plant for disposal.

Sunderland Exhibition.—The electric lighting of this exhibition will be carried out by Messrs. Ernest Scott and Mountain.

Electric Bells.—Messrs. Julius Sax and Co. have been asked to give a price for fixing electric bells at the Strand Union casual wards.

Manchester.—New Inland Revenue offices are being built in Deansgate. It is probable that they will be lighted throughout by electricity.

Pupils.—The Electrical Power Storage Company, of 4, Great Winchester-street, E.C, have a vacancy for one or two premium pupils or improvers.

Wellingborough.—Arrangements have been made for the installation of the electric light throughout the extensive sidings on the Midland Railway at Wellingborough.

Rochdale.—The whole of Duckworth's Hotel is now lighted electrically. The installation comprises a Crompton dynamo driven by a 12-h.p. Stockport gas-engine.

Cardiff.—The stores known as the Hayes Market, belonging to Messrs. David Rees and Co., are to be reopened to-day. They have been lighted throughout electrically.

Exploitation, Limited.—This Company has been registered with a capital of £1,250 to carry on business as mechanical, civil, electrical, hydraulic, and general engineers.

Blackburn.—A new church, to be called St. Silas, is to be built here. Although the usual gas fittings are to be put in, it is not unlikely that the electric light will be introduced.

Southall.—The opinion has been expressed at a meeting of the Southall-Norwood Local Board that the district has not yet reached a stage at which the electric light can be introduced.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending 26th inst. amounted to £1,094, as compared with £778 in the corresponding week of last year.

Leeds.—The Leeds Corporation Lamp Committee have appointed a sub-committee to consider a proposal made by the House-to-House Electricity Company to illuminate certain public thoroughfares.

Stalybridge.—Messrs. Parker and White have purchased the works of Messrs. Millburn, Sons, and Co., Limited, Stalybridge, and will start business there as ironfounders and electrical engineers.

Leeds Tramways.—The Corporation Tramways Committee left Leeds on Wednesday morning on a visit to the Isle of Man, for the purpose of inspecting the electric tramway from Douglas to Laxey.

Margate.—Letters have been received from two companies, who give notice of their intended applications to Parliament for provisional orders empowering them to supply electric light to this borough.

Saycoe Electrical Syndicate, Limited.—This Company has been registered, with a capital of £10,000 in £1 shares, to acquire and turn to account certain patents relating to improvements in primary batteries.

Kendal.—Tenders have this week been invited for the placing of telephonic communication between the gas company's offices, Parkside-road, and borough treasurer's office, 69, Highgate, for the Kendal Urban Sanitary Authority.

Elmore Copper.—The name of Elmore's Patent Copper Depositing Company, Limited, has been placed on the list of contractors to the War Department as a result of tests made upon Elmore copper, which has been approved by the Government.

Bristol.—The Electrical Committee met at the Council House on Friday, Mr. George Pearson being in the chair. The committee decided to alter the position of one arc lamp in College-green, and to erect two additional lamps, one on each side of the Queen's statue.

Dissolution of Partnership.—The partnership heretofore subsisting between Mr. Sydney Cummins Smith and Mr. William Habgood, carrying on business as electrical engineers, at Great Missenden, in the county of Buckingham, under the style of Habgood and Smith, has been dissolved.

Nottingham.—The central station is now rapidly approaching completion. The boiler-house, engine-room, and battery-room are all practically finished, and as the whole of the necessary machinery has also been laid down, there is every probability of the station being started at an early date.

Glasgow.—Plans have been prepared by Messrs. Bruce and Hay, 261, West George-street, Glasgow, for extensions of the warehouse of Messrs. Copland and Lye, Sauchiehall-street. It will be lighted electrically, and be provided with electric lifts.

City and South London Railway.—The receipts of the Company for the week ended August 26 were £878, against £719 for the corresponding week of 1893, or an increase of £159. The total receipts for the current period of the present half-year amount to £6,942, as against £6,647 in the corresponding period of 1893.

Portsmouth.—The Portsmouth Town Council have decided to apply to the Local Government Board for sanction to the borrowing of £1,265 for the purpose of extending their electricity distribution system. On the 1st inst. there were, exclusive of the public lighting, 3,517 16-c.p. lamps connected with the mains.

Taunton.—The globes of the arc lamps having been damaged by catapults, the Council have decided to offer a reward of £1, to be paid to the person giving information on the conviction of any person damaging the globes or plant. The electric lighting station, machinery, and plant have been insured in the Atlas Insurance Office for £6,000 at 4s. per cent.

Johnson and Phillips.—This firm inform us that they are at present very busy with numerous large orders in their cable department, especially in their indiarubber shops, manufacturing house-wiring cables and wires. Very few of the latter are now used, the majority of engineers specifying that only stranded conductors may be employed on the works.

Wolverhampton.—On Tuesday a meeting of the shareholders in the Wolverhampton Gas Company was held, at which Mr. J. Annan, the engineer, referring to the introduction of the electric light into the town by the Corporation, said it would not be a great disadvantage to the company, as alterations and improvements were being effected at the gasworks which would enable the company to hold their own.

Bath.—Alderman Sturges has reported to the Town Council that the Lighting Committee, having considered the further correspondence from the electric light company with regard to their application for a provisional order, were still of opinion that it should be resisted. He was in favour of the Corporation having a free hand at the end of the present license of seven years. The recommendation was adopted.

Aberdeen.—It has been reported to the Education Committee of Robert Gordon's College that the new installation of electric light from the city mains for the college and the school of art was expected to be completed in about a week. The contracts accepted for the work were £200 less than the estimate. In view of the circumstance that the installation was entirely new, the committee agreed that there should be a formal inauguration. The date has yet to be fixed.

Hertford.—The Lighting Committee of the Hertford Corporation have drawn up a report recommending to the Corporation that the proposed electric lighting scheme be carried out as speedily as possible; that the engineer be instructed, with the assistance of the borough surveyor, to prepare the detailed plans for carrying out the scheme and the requisite forms of tender; and that application be made to the Local Government Board for their sanction to a loan of £6,000 for carrying out the scheme.

New Installations.—Messrs. Rashleigh Phipps and Co., of 102, Oxford-street, have recently fitted up a large number of installations for Colonel Edis, the well-known architect of Fitzroy-square, and they have now been entrusted with the lighting of his house throughout. This firm have also received a contract for the whole of the fittings for the new Conservative Club in Glasgow. This club is a very large one, and the building is second to none in Glasgow. The Hon. Percy Allsopp, of Park-street, has also entrusted the lighting of his house to this firm.

Akroydon.—It is now several years since Mr. Milner, of the Woodside Mills, first introduced the electric light into Elland. His example has been followed by one or two manufacturers, and now Messrs. James Dyson and Co., of the Atlas Soap Works, are putting down an installation. A dynamo, made by Mr. J. A. Edmundson, Bradford, runs at 1,000 revolutions per minute, and has an output of 135 volts and 67 amperes. This will feed, perhaps, 60 lamps in the works varying in power from 16 to 25 candles, and 70 other lamps at the new house which Mr. Sam Dyson, Parkfield, has built in Victoria-street.

Crompton and Co., Limited.—An extraordinary general meeting of the shareholders was held on Wednesday, when Mr. R. E. Crompton, who presided, moved the confirmation of a resolution passed on the 13th inst., to the effect that the capital of the Company be reduced from £300,000 to £280,000 by cancelling paid-up capital which has been lost, or is unrepresented by available assets, to the extent of £20,000; and by cancelling 4,000 ordinary fully-paid-up shares of the Company, numbered 2,785 to 6,784 inclusive, which have been issued. The Chairman said the objects of the resolution were fully explained at the previous meeting. The resolution was adopted.

Belfast.—Mr. Greenhill has stated at a meeting of the Harbour Board that it was a matter of interest for the public to know that the Great Northern Railway had arranged for an installation of the electric light for the inspection of cattle after sunset during the winter months. This arrangement would enable dealers to send down their cattle by later trains. He trusted that the other railway companies having termini in Belfast would follow the example of the Great Northern, with the result that there would be a general improvement in the cattle traffic of the port. Mr. Davidson said the new light would be a decided advantage, as the steamers in future were to start an hour later from Belfast.

Digitized by Google

Londonderry.—A special meeting of the Corporation has been held, at which a report was read from Mr. Christie, the resident electrical engineer. The report contained a list of occasions on which the electric cable had fused and been cut and repaired. The breaks were in all parts of the system. Councillor Turner was proceeding to question Mr. Christie, when the Mayor asked the Council, in the interests of the citizens and the Corporation, to reserve any observations on the subject until they had before them a report on the cables from Mr. Blake, the electrical engineer under whom the works were constructed. Mr. Blake said he had only returned to town, and had not had time to draw up a report. He admitted that these breaks constituted a serious feature, and would require to be put right.

Penzance.—The Town Council have been discussing the question of the lighting of the public lamps. Mr. Ludlow read the report of the Lighting Committee, showing the expenditure was £12. 9s. 7d. during the past five weeks. The committee recommended the acceptance of the gas company's tender, subject to the third clause being modified to the extent that the Corporation pay for opening and closing trenches for gas mains when used for supplying gas to public lamps only. Mr. Ludlow said the tender of 3s. 8d. was the same as before, but this clause, requiring the Council to open and close all trenches of present and future lamps, was the thin end of the wedge to get the electric light in. They were obliged to accept the tender as they were quite in the hands of the company. That really brought up the price. The report was adopted.

Ilkley.—An enquiry was held at Ilkley by Mr. F. H. Tulloch, Local Government Inspector, into an application by the Ilkley Local Board for sanction to borrow £2,600 for additions and alterations to the gasworks. Mr. Gaunt objected to the loan on the ground that the Local Board had already expended too much in the purchase of gasworks, and that a debt was likely to be created which he considered objectionable and unnecessary. Instead of spending so much on gas, he contended that the Board ought to have endeavoured to supply the electric light. The electric light was wanted in Ilkley, and it was very likely they would get it, but if the Local Board had gone in for electric light first, they could have bought the gasworks at a far less sum than they had paid. A note was taken of the objection, and the inspector viewed the works.

Colchester.—The Lighting Committee of the Town Council have, before deciding as to the establishment of the needful works for lighting a portion of the borough by electricity, issued a circular to the inhabitants of the district proposed to be lighted—viz., High-street, Head-street, North-hill, Crouch-street, St. John's-street, Queen's-street, part of Culver-street, St. Nicholas-street, St. Botolph-street, Long Wyre-street, and Short Wyre-street—with the view to ascertaining the extent to which such inhabitants are desirous of availing themselves of the electric light. The committee, after giving particulars in reference to the estimated cost of the light and fittings, distinctly state that the income to be derived from the works, if established, should be sufficient to render the undertaking self-supporting, in order that no charge may be made upon the rates.

Whitechapel.—An important report has been submitted to the Whitechapel District Board of Works by the committee of that body having charge of the scheme for the electric lighting of the district, for which powers were obtained some two or three years ago under a provisional order of the Board of Trade. The Streets Committee have been at work, with the assistance of Prof. Robinson, but have not come to any decision, and have submitted a detailed account of their labours for the opinion of the whole Board. The first scheme for lighting the prescribed area was estimated to cost £52,300; three alternative schemes were afterwards submitted, the total capital outlay being respectively £72,250, £74,750, and £84,250. In each case proportionate incomes are estimated to be received from supplying private consumers, but whether those amounts will be realised or the total expenditure exceeded are matters for consideration. The great feature in the local proposal, and it is one on which any scheme decided upon will be acceptable, is that the Whitechapel destructor premises can be used as a station, and the present waste heat of the furnaces utilised for generating purposes. The Board's consideration of the matter has been adjourned until October.

Bromsgrove.—In our last issue we referred to the position of the subject of the electric light here, and mentioned that a public meeting was to be held on Thursday evening last week. At this meeting there was a large attendance. Mr. D. Laing presided, and explained that the meeting was called to consider the application of Messrs. Hemming and Co., Birmingham, to the Local Board for permission to lay down electrical plant in the town. Mr. Bown said he was willing to move a resolution expressing the meeting's approval of granting the application, subject to such regulations as the Local Board thought it necessary to impose. Some of the working-men in the meeting expressed dissent at any restrictions being imposed, and Mr. Bown pointed out the necessity for regulations to preserve the streets and the other property of the Board. He went on to say that if Messrs. Hemming meant business he was sure the meeting would be unanimous in saying, "Come and welcome." A good deal of sympathy had been expressed with the gas company in this matter, but no one had expressed sympathy for the poor sellers of lamps and petroleum, and it was adding insult to injury to ask him to move such a resolution, for he might lose the sale of so many barrels of petroleum; but he did not care for that. He moved, "That in the opinion of this meeting it is desirable that the request of Messrs. Hemming be complied with, subject to any conditions which it may be necessary to impose." Mr. Wright, secretary of the company, being called upon, explained that the company could proceed by applying at once to Parliament for a provisional order, or they could apply to the Board of Trade for a license, and in the latter case it was necessary first to obtain the consent of the Local Board. In reply to the question whether the company meant business, he said they would not proceed to lay down their plant immediately the consent of the Local Board was obtained, but would proceed to ascertain what amount of support it was probable they would receive from the town. The Rev. E. Pine Hall seconded the motion, which was carried unanimously.

The Newcastle Tramways.—The Newcastle Tramways Committee have met to consider the resolution come to at a meeting of the Council—namely, that the Tramways Committee should prepare a scheme for the working of Westgate-hill, Arthur's-hill, and Stanhope street district with cable trams. Mr. Eustace Smith met the committee, and a conference was held as to the new company, of which he is a promoter, taking up the section alluded to. Mr. Smith stated that it would be almost impossible to work so short a section profitably, as it would only be equivalent to four miles, and it would entail the putting up of an engine-house near the workhouse. If the cable trams were extended over the city, such engine would be of no use, as they would really require two engine-houses somewhere in the centre of the town to work the two sections. Thus the cost involved in building the new engine-house, etc., would be lost. From the experience gained in Edinburgh it was ascertained that the cost of working a tramcar for a short distance of four miles was at the rate of 10d. per mile; for six miles, 9d.; and for 12 miles, 7½d. per mile; or a difference of £7,000 in the revenue. The committee, however, requested Mr. Smith to entertain the scheme as agreed upon by the Corporation, and to state upon what terms his firm could work it, and if they could not see their way to take it over on certain terms, to say what they would be prepared to offer for the section alluded to and a further extended portion in the city. A letter was read to the committee from Messrs. Leadbitter and Harvey, on behalf of gentlemen interested in electricity, whereby they suggested to run a line from the central station to a point opposite the church in Church-street, Walker. They undertook to work such line by the conduit system to the Walker New-road, and from there down to the terminus at the Walker Church. They proposed to have overhead wires on poles to be placed on one side of the road, but in no case were the wires to cross the road. The committee decided that the matter should stand over pending the decision on Mr. Smith's proposal.

Edinburgh.—The Cleaning and Lighting Committee of the Town Council, on a statement from proprietors and tenants in the district, recommended that George-street, Charlotte-square, and St. Andrew-square, and the streets leading from these to Princes-street, should be lighted by electricity. Bailie Steel proposed that the recommendation be not agreed to. He suggested that they should pause until they saw the result of the installation already sanctioned. Treasurer M'Crae seconded. If they agreed to this proposal, there was no street in the city that could be excluded from the electric lighting scheme. They had again and again increased their public electric scheme, and the question was where they were to stop. Bailie Gulland proposed the adoption of the committee's recommendation. He maintained that fairplay to the business community in George-street and the adjoining streets demanded that these streets should be lit with electricity. Mr. Mortimer seconded Bailie Gulland's motion. George-street, he said, was at present one of the worst lit streets in the city. Mr. Mackenzie pointed out that, altogether apart from the question of electric lighting, the Corporation must lay their minds to improving the public lighting of the streets. At present they spent 1¼ cubic feet per hour on their street lamps. In the large English towns they consumed about 5 cubic feet per hour. Manchester, with double the population of Edinburgh, spent four times as much as Edinburgh on public lighting. He did not believe there would be a deficit on the electric lighting scheme. Manchester had set up an installation at a cost of £127,000, and in the very first year the deficit was only £238 after paying all expenses. After some further discussion, the Lord Provost, in supporting the amendment, pointed out that they would be introducing a novel principle if they lighted the streets here proposed, and a principle which would bring a great deal of trouble upon their heads. The committee had recommended the lighting of people and not of property, but here they were going upon the principle of lighting property and not people. Once they did that they would have people from all parts complaining that their property was not lighted. On a division, Bailie Steel's motion was carried by 14 votes to 12 given to Bailie Gulland's.

Salisbury.—The Town Council, acting as the Urban Sanitary Authority, recently held a meeting for the purpose of receiving the minutes of a committee meeting of the Authority, and to consider the draft form of license which the Salisbury Electric Light and Supply Company, Limited, sought to obtain from the Board of Trade. The town clerk reported that at the committee meeting a copy of the draft form of license was considered, and that a resolution was passed requesting Mr. Hammond to insert therein such conditions and modifications as he might deem expedient, with a view to the same being considered at that special meeting. The Council decided that Mr. Gramshaw, representing the company, should be admitted, but that the draft form of license, as amended by Mr. Hammond, should be read before he was invited into the room. The draft of the license (which, it was stated, would absolutely expire at the end of seven years, or would

Digitized by Google

certainly be revoked by the Board of Trade on the issue of a provisional order which was to be applied for) was then read. This was discussed, and Mr. Gramshaw was then called into the room, and the alterations in the draft form of license suggested by Mr. Hammond were communicated to him. The only objection raised by Mr. Gramshaw had reference to the proposed purchase clause, which he contended was unnecessary. He remarked that the license was simply, so to speak, a permission given on the part of the Board of Trade to save time, whereas the provisional order was really the legal engagement, and under this the Authority would have a greater *locus standi*. The Authority would have plenty of time to discuss the question of purchase when the provisional order was applied for, and he would see that a clause was inserted in the order; but if they were to decide on such an insertion now in the form of license it would create a precedent for the provisional order which would not be fair to the company, which was in its infancy, and had not yet made any contract. It was not fair to the company either to ask them to insert in the license something which was not usually inserted in such cases. The company could not accept the proposal, but if the Authority insisted on the insertion of the clause, they would go to the Board of Trade and lay the facts before them, as he had laid them before the Council. Mr. Pyesmith moved that the license should be drafted without any reference to a purchase clause, and that both the Corporation and the Authority should be left entirely free to deal therewith when the same came up for discussion in the provisional order. Alderman Brown seconded the motion, which was agreed to. It was understood that the provisional order would be applied for in the parliamentary session of 1895. The Mayor moved, and Mr. Scamell seconded, that Mr. Hammond should be empowered, on behalf of the Sanitary Authority, to lodge the draft license with the Board of Trade, subject to such alterations therein as had been approved by the Council. This motion having been carried, the proceedings terminated.

PROVISIONAL PATENTS, 1894.

AUGUST 20.

15789. **Improvements in thermo-dynamic motors.** Francis William Crossley and James Atkinson, Openshaw, Manchester.

15825. **Improvements in constructing electric cartridges for fog signalling on railways.** Herbert Brocklehurst and Henry Constien, 24, Cheyne-court, Chelsea, London.

15843. **An improved telegraphic apparatus for transmitting domestic orders or other signals.** Louis Boudet and Pierre Lacombe, 18, Buckingham-street, Strand, London.

15858. **Improvements in permanent ways for electric railway and tramway vehicles.** Jean Claret and Olivier Wuilleumier, 47, Lincoln's-inn-fields, London.

AUGUST 21.

15899. **An improvement in copper castings for electrical purposes.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Eugene Obach, Germany.)

15900. **Improved means for preventing variations in the regulation of shunt arc lamps for alternating currents.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Messrs. Siemens and Halske, Germany.) (Complete specification.)

15920. **Improvements in and connected with primary batteries.** George Herbert Reid, 55, Chancery-lane, London.

15921. **Improvements in the electrical propulsion of boats and vessels.** Anthony George New and Arthur James Mayne, 55, Chancery-lane, London.

AUGUST 22.

15985. **Improvements in or connected with electric arc lamps.** William Hopkin Akester and Henry Herbert Price, 57, Chancery-lane, London.

16002. **Improvements in apparatus for refining metal by electrolysis.** Henry Alonzo House, Henry Alonzo House, jun., and Robert Rintoul Symon, 115, Cannon-street, London. (Complete specification.)

AUGUST 23.

16097. **Improvements in and relating to electric high and low tension fuse heads for use in blasting.** Tom Malson, 54, Fleet-street, London.

16100. **Improvements in apparatus for use in the electrolysis of alkaline chlorides and other alkaline salts.** Henry Auer and Ferdinand Hurter, 47, Lincoln's-inn-fields, London.

16105. **Improvements connected with the electrical deposition of zinc and other metals.** Richard Heathfield and William Stepney Rawson, 1, Leadenhall-street, London.

AUGUST 24.

16106. **Improvements in galvanometers.** Arthur Ford-Lloyd, 5, Hunter-street, London.

16112. **An adjustable electric contact specially designed for safe and strong-room doors.** Frederic Charles Geary, Church Gresley, Burton-on-Trent.

16131. **Improvements in electric signs and advertisements.** William David Hawksey and Ivie Mackie Lamb, 70, Market-street, Manchester.

16145. **Improvements in electrolytic processes and apparatus.** Cornelius Hessel, 21, St. Julian's-road, Kilburn, London.

16156. **Improvements in and relating to electric winding engines, locomotives, and other electric motors, chiefly designed for use in mines.** Bruno Lebrun, 45, Southampton-buildings, Chancery-lane, London.

16162. **Improvements in accumulators or secondary batteries.** Moricz Engel, 28, Southampton-buildings, Chancery-lane, London.

16163. **Electrical apparatus for controlling the motion of cranes, travellers and other similar apparatus.** John August Essberger and Alexius Wilhelm Geyer, both of the firm Union Electricitäts-Gesellschaft, 28, Southampton-buildings, Chancery-lane, London.

16191. **Improvements in or relating to electric bells and other sounding or indicating devices.** Samuel Quincey, Philip Benns, and Henry Belham, 46, Lincoln's-inn-fields, London.

16192. **Improvements in or relating to electric bells and other sounding or indicating devices.** Samuel Quincey, 46, Lincoln's-inn-fields, London.

AUGUST 25.

16243. **Improvements in the electric propulsion of cars.** Archibald H. Brintnell, 4, South-street, Finsbury, London. (Complete specification.)

SPECIFICATIONS PUBLISHED.

1893.

16467. **Working electric tramways.** Anderson.

15217. **Electric cables.** Dymond. (Thompson.)

15231. **Electric arc lamps.** Boult. (Bureau.)

15486. **Electric switch.** Mann and Hopwood.

18602. **Telephone switchboards.** Abel. (Société Générale des Téléphones Reseaux Téléphoniques et Construction electriques.)

18690. **Conduits for electric conductors.** Picking.

1894.

8761. **Electric fire-alarms.** Archibald and Tarry.

12875. **Alternating-current meter.** Kelley and Stanley.

NOTES.

Madras.—The locomotive department of the Madras Railway is building 50 cars for the Madras Electric Tramways.

Football by Electric Light.—A football match has been played at Rochester at night, with the aid of the electric light, before 3,000 people.

Mysore.—It is stated that preparations are being made to light by electricity the whole of his Highness the Maharajah's banqueting hall at Mysore.

Brussels Tramways.—A Brussels paper states that three accidents have recently taken place in connection with the working of the electric tramways in this city.

Personal.—Prof. Helmholtz celebrated his seventy-third birthday on the 31st ult. He is now much better, and it is hoped that his complete recovery will soon take place.

French Contemporaries.—The cessation in the publication of *La Lumière Electrique*, which has recently taken place, has also abruptly terminated the existence of *Electricité*.

Electric Cooking.—A food and cookery exhibition has been opened at the Exhibition Hall, Rusholme-road, Manchester, at which daily demonstrations are given of cooking by electricity.

Mediterranean Trip.—The "Electra," with Sir John Pender and his party, including Lord Wolseley, Sir Evelyn Wood, Lord Portsmouth, and others, on board, left Athens on Monday *vid* the Canal of Corinth, for Genoa.

Telegraphic Nomenclature.—The ninth edition of the "Nomenclature Officielle des Bureaux Télégraphiques," published by the Bureau International des Administrations Télégraphiques, of Berne, will be issued in a few days.

Telephony in Belgium.—According to the *Etoile Belge*, Belgian-Dutch communications have been going on by which a telephone line will be established between Brussels and Antwerp and Amsterdam and Rotterdam.

Electric Traction Systems.—Mr. J. M. Nicol, of Plymouth, has contributed an article on electric traction to the *Western Morning News*, in which he has dealt more especially with the Pollak and Binswanger closed-conduit system.

Institution of Engineers and Shipbuilders.—We have received Part 9 of Vol. X. of the *Transactions* of the North-East Coast Institution of Engineers and Shipbuilders. It contains the constitution, by-laws, and list of officers and members.

Hampstead.—The date for the public starting of the supply of electric light at Hampstead has been fixed for October 1. The North-Western Hospital of the Metropolitan Asylums Board will, it is said, be the largest private consumer.

Hospital-Lighting.—The new hospital at Birmingham, which will be inspected by the Duke of York to-morrow (Saturday), is lighted throughout by electricity. In addition to this, two fans driven by electric motors have been installed for ventilating purposes.

Paris-Madrid Telephony.—Paris and Madrid will shortly be telephonically connected. On the Spanish side the line extends from Madrid to Saragossa, and on the French side from Paris to Tarbes. The section between Tarbes and Saragossa has still to be connected.

Electric Traction in Italy.—An application has been made by Mr. Guiseppe Ferrando to the Mayor of Palermo for a concession for the construction of four tram lines in that town to be worked by electric cars. It is proposed to erect the power station in the Piazza Ucciardone.

Royal Photographic Society of Great Britain. A soiree of this society will be held on Saturday evening, 22nd inst., in the gallery of the Royal Society of Painters in Water-Colours, 5A, Pall-mall East. The thirty-ninth annual exhibition of the society will open on the 24th inst., and will be continued until November 14.

Electro-Harmonic Society.—The concerts of the Electro-Harmonic Society this season will be six in number, and will take place on the evenings of the following dates: September 28, smoking concert; October 26, smoking concert; November 30, ladies' night; January 25, 1895, smoking concert; February 22, ladies' night; and on March 29, smoking concert.

Electric Traction on Railways.—Mr. A. B. Kitching, the chairman of the Mersey Railway Company, at the half-yearly meeting of the company held on Thursday last week, stated that the directors had made enquiries as to the practicability of working the railway by electricity, and these enquiries were still going on. As far as they had gone, the information was rather encouraging.

Going Up.—Business seems to be improving in the electrical industries, if Stock Exchange quotations are any indication. During the past week there has been (as will be seen from our companies' stock and share list) a rise in the shares of the Brush Company, Indiarubber Company, Henley's Works, some Elmore companies, some supply companies, and the National Telephone Company.

Lightships and the Electric Cable.—A petition has been forwarded by Mr. E. J. Hobbs to the member for Thanet, expressing satisfaction with the great success of the cable connection between the North Sands Head and Kentish Knock light-vessels and the shore, and asking Parliament to sanction the connection of the remaining 240 lightships round the coast, and especially the East Goodwin light-vessel.

New Electric Launch.—A demonstration of the capabilities of the electric launch "Velvoca" will be given on Monday next by the Battery and Motor Company, of St. Margaret's Offices, 53, Victoria-street, S.W. The launch will start from Petersham Island, Richmond, at 3 p.m. The current is obtained from 48 Velvo-carbon primary batteries, each of which, we are informed, weighs 30lb. The output is said to be 60 amperes for 10 hours.

University College, London.—The lectures and practical work in the engineering and chemical laboratories at University College, London, will commence on 2nd proximo. The courses, as will be seen by our advertisement columns, are in civil, mechanical, and electrical engineering, graphics, and architecture. Copy of prospectus may be obtained of Mr. J. M. Horsburgh, M.A., secretary, University College, Gower-street, W.C.

Gas and Electricity.—That the competition of the electric light is bringing down the price of gas is being shown in different parts of the country. Two or three weeks ago we noted this fact in connection with Hanley, and now the Croydon Commercial Gas Company have decided to reduce the price "in view of the possible advent of the electric light." Gas companies, it would appear, are beginning to feel the shoe pinch more keenly than ever.

Gross Exaggeration.—"I do not think," says the Scotch correspondent of the *Journal of Gas Lighting*, "the citizens of Edinburgh realise that electric lighting will cost them about £50 per lamp per annum, or, if they did, I am persuaded they would not go in for so extensive a scheme." Our office boy says that he intends to proceed to Scotland

Digitized by Google

to learn the gentle art of exaggeration from the correspondent in question. Will our contemporary oblige us with his address?

Electrical Machinery.—We have received from Messrs. Ernest Scott and Mountain, Limited, Close Works, Newcastle, their new catalogue of electrical plant and machinery—a well-printed and well-illustrated book. The sections respectively deal with general particulars of lighting, Tyne dynamos for all purposes, transmission of power, motive-power plant, arc lamps, electrical accessories, electric light fittings, bells, telephones, domestic apparatus, and engineering specialities, and machinery. There is a good selection of dynamos, and the motor plants include various pumps for mining purposes, winding and haulage plant, electric cranes, lifts, wharf capstans, launches, mining drills, coal-cutters, fans, and blowers.

Launches on the Thames.—Mr. Fras. F. Ommanney has sought the columns of the *Standard* to ventilate a complaint concerning the danger caused to small boats by large launches on the upper reaches of the Thames, with special reference to recent fatal accidents. He suggests, with a view to prevent such accidents, "the following further restrictions for the consideration of the powers that be: (1) no vessels propelled by steam, oil, or electricity to exceed 40ft. by 7ft.; (2) no such vessel to travel at a greater speed than 'slow'; (3) at locks, launches to wait until after pleasure boats have gone through, and not to approach within a hundred yards of lock gates except by permission of authorised lock-keeper; (4) all pleasure craft to carry lights after dusk."

A Gassy Contemporary.—Our contemporary the *Journal of Gas Lighting* prints an editorial on "Petroleum or Gas for the People." Of course the conclusion of the article is that efforts should be made by "those who are responsible for the popularisation of gas to persevere in their endeavours to facilitate the employment of this means of lighting where it is most likely to do most good." Why not take it to Africa then, dear *Journal*—there "it is most likely to do most good" among the niggers. Gas and petroleum are about in the same boat as regards safety (?), but the nose of the former is gradually being put out, and in this case, as also when American papers refer to it as the *London Journal*, the *Journal* does not like it. The decrying of the use of oil lamps by a gas journal is simply paradoxical.

State Telephony.—In an article published in the *Elektrotechnische Zeitschrift* of August 16, Mr. J. Baumann discusses the question of telephony, and points out that the working and management of telephone systems are in the possession of the Governments of Germany, Belgium, France, Austria-Hungary, Luxembourg, Switzerland, Roumania, and Bulgaria. In Sweden both the Government and a private company operate telephone exchanges, the extent of the services being practically equal. This fact, the author suggests, shows that it is only a question of time when the whole of the European countries will be placed in communication with each other by means of State telephone networks, similarly to the telegraph systems. The author then passes on to consider the question of telephone rentals.

New Steamer.—A new steamer, named the "Duke of York," and intended for service between Richmond and Hampton Court, was launched on Saturday from the yard of the Thames Electric and Steam Launch Company, Eel Pie Island, Twickenham. The steamer has been designed by Mr. W. S. Sargeant. It affords accommodation for 300 passengers, and is said to be the largest launch on the Thames above Richmond Lock. Her length from stem to taffrail is 80ft., with beam 14ft., depth 7ft., and draught about 3ft. 6in. The main saloon is artistically decorated, and down the centre of the skylight are ornamental lacquered brass electroliers fitted with incandescent lamps. The vessel is propelled by a single screw, having three blades of Bull's metal supplied by the Phosphor Bronze Company. The motive power is provided by a pair of compound surface-condensing engines of the marine type.

Electric Lighting in Germany.—Although the Chemnitz central station has not been long in operation, the demand has been such that steps are being taken to extend it next spring. A second feeder is being laid down, the first supplying 7,000 incandescent lamps, 225 arc lamps, and 30 h.p. for electromotors. The electric light is being introduced into Geringswalde and Bruck-on-the-Maine. The Municipality of Landstuhl have decided to take current from Messrs. Bumb and Herrle, a local engineering firm. The town will lay its own cables. The Cologne Municipality have decided to light the High-street and the district surrounding the cathedral electrically from the municipal central electric light station. Some of the lamps supplied by the Helios Company for this purpose are already in use. They are hung from steel wires stretched across the streets, which are narrow. The Municipality of Mannheim have issued circulars to ascertain the probable demand for current.

A Simplon Electric Railway.—The project of piercing the Simplon from the Swiss to the Italian side has now made another step forward. When the scheme of constructing the tunnel was approved by the Swiss Confederation and the Italian Government, a committee of three eminent engineers was appointed to examine the mountain and report upon the best means of constructing the new line. Sir Douglas Fox was asked to form one of the committee, and he undertook the task in conjunction with Messrs. Wagner and Colombo, the former a famous Austrian engineer, and the latter of equal rank in his profession in Italy. These gentlemen have now concluded their labours, and although their report has not yet been formally presented to the Italian and Swiss Governments, its tenor has been made public. Sir Douglas Fox deals specially with the question of the ventilation of the proposed tunnel, and recommends that electricity should be used entirely for traction purposes. If electric traction is used, there will be no special ventilating machinery required.

Electric Lighting in Australia.—According to the *Melbourne Age*, the second reading of an Electric Lighting Bill was moved in the Legislative Assembly on July 17. Mr. Wynne, who moved the second reading, said the time had arrived when some system should be introduced for the regulation of the supply of electricity. This Bill was very similar to the one introduced by the president. It was necessary for the interests and the safety of the public that control should be provided for regulating the operations of companies and their dealings with municipalities in the supply of electric light. Arrangements were made by which local councils could either construct the works or let that power to a company. A council would be empowered to strike a special rate. Companies would be required to supply information of their profits and of the manner in which they had dealt with the concession. Right of purchase by the municipal councils was provided for. There was a limitation of profits to 10 per cent. dividends, and the consumers were given the benefit of a reduced rate, as the dividends might be increased in proportion to a specified rate of reduction in the price of electricity. The discussion was adjourned.

Digitized by Google

Polarisation of a Thin Metal Partition in a Voltameter.—Mr. J. Daniel, in the *Phil. Mag.*, mentions that when a thin metal partition is introduced between the poles of a voltameter, gases are evolved at its surface, but if the thickness of the partition is below a certain limit, the current passes without evolution of gas and without evident polarisation. The author finds that the "critical thickness"—that is, the least thickness of partition through which the current passes without polarisation—is 0·00009mm. for gold, 0·00015mm. for platinum, and 0·0005mm. for aluminium, with a small current and a good conducting electrolyte. The "upper critical limit"—that is, the smallest thickness for which the polarisation is the same as for very thick plates—is about 0·004mm. under the above conditions. Between the critical limits the polarisation increases with the thickness. Special experiments indicated that in the case of copper sulphate solution the passage of the current was not accompanied by the passage of copper ions through the gold-leaf partition, but rather that the copper sulphate itself diffused bodily through the membrane.

Gas and Electricity in Berlin.—A report issued by the Aeltesten der Kaufmannschaft über die Handels und Industrie Verhältnisse, of Berlin, deals with the question of the influence of the introduction of the electric light on the consumption of gas. It appears that the adoption of electric lighting is having a considerable effect in Berlin in spite of the hopes which were entertained of the increased use of gas for heating and cooking purposes. For many years the consumption of gas rose annually by from 4 per cent. to over 6 per cent. each year, and even in 1892 the increase amounted to about 3,250,000 cubic metres, or about 3¼ per cent. compared with 1891. Last year, however, the consumption fell by nearly 1,000,000 cubic metres. Private gas consumers used 1,750,000 cubic metres less. This is attributed to the unfavourable condition of business, to the competition of the electric light, and to the economy of the Auer incandescent gas lamp. More use is being made of gas for heating, cooking, and motive-power purposes. Electricity has made great headway during the past year not only as regards the current taken from the central station of the Berliner Elektricitätswerke, but in private installations. The latter have decreased in number from 301 to 280, but the number of lights thus supplied has risen by 6 arc and 14,406 incandescent lamps, so that at the close of the year there were 3,869 arc lamps and 69,632 incandescent lamps connected with private installations. The Berliner Elektricitätswerke at the end of the past year supplied 4,931 arc lamps, 102,705 incandescent lamps, and 322 motors. The total increase in electric lamps during the past year was 19·96 per cent.

Internal Arc Lighting.—In discussing the subject of lighting rooms by means of arc lamps, Mr. F. Nerz in the *Elektrotechnische Zeitschrift* of August 30 dismisses as being out of the question dwelling-rooms where two or three gas or petroleum lamps are in use. When, however, the demand for light is greater than this, he states that arc lamps can be employed with advantage, and, although no saving may be effected, more light and a more even illumination are obtained than is the case with incandescent lamps, gas, or petroleum. In order to impart a warm tone to small arc lamps of from two to four amperes for internal illumination, we must take care first of all that the quantity of light directly beaming forth is diminished as much as practicable, but that the distributed light is increased. This may be accomplished (1) by increasing the obscuration of the surrounding globe of the lamp, (2) by augmenting the diameter of the same, and (3) by the addition of means for a further distribution of light. The author states that when properly applied the increase in the obscuration of the globe does not bring about those disadvantages generally imagined. Let us take the ordinary globe, and by giving it a thicker coating we shall considerably diminish its transparency, and at the same time increase the distributing effect. If we measure the lighting power in the room without and with a globe, we find in the latter case an important diminution in the value for the zone of highest intensity, and an increase in all other points of the room. Let us insert between the source of light and the globe a light-distributing means. The Schuckert Company, according to Mr. Uppenborn's proposals, place in their lamps for internal illumination a small glass cone arranged at the point of illumination, and this gives a good effect. The author then goes on to deal with other forms of lamps in which improvements have been introduced for the purpose of increasing the distributing effect.

The Latest Dalzielite Story.—Some of the items of news transmitted to this country by Dalziel's Agency are truly remarkable. One of the latest efforts of their Paris correspondent is the following: "A series of very wonderful experiments, which have just been concluded by Dr. Luys, whose observations and discoveries in connection with magnetism and electricity made a profound impression upon the scientific world some time ago, has led to a remarkable result. The latest discovery establishes the fact that cerebral activity can be transferred to a crown of magnetised iron, in which the activity can be retained and subsequently passed on to a second person. Incredible as this may seem, Dr. Luys has proved its possibility by the experiments just referred to. He placed the crown, which in reality is only a circular band of magnetised iron, on the head of a female patient suffering from melancholia, with a mania for self-destruction, and with such success was the experiment attended that within a fortnight the patient could be allowed to go free without danger, the crown having absorbed all her marked tendencies. About two weeks afterwards he put the same crown, which meanwhile had been carefully kept free from contact with anything else, on the head of a male patient suffering from hysteria, complicated by frequent recurrent lethargy. The patient was then hypnotised, and immediately comported himself after the manner of the woman who had previously worn the crown. Indeed, he practically assumed her personality, and spoke of himself as a woman, and uttered exactly the same complaints as she had done. Similar phenomena, it is reported, have been observed in the case of every patient experimented upon. Another experiment showed that the crown retained the impression acquired until it was made red-hot." It is not likely that anyone would care to have the cerebral activity of this enterprising reporter transferred to him.

Electric Travelling Cranes.—In our last issue some particulars were given of the great 60-ton overhead crane at the Seraing works of the John Cockerill Company; and we then expressed doubts as to whether this was not the largest of its kind as yet built. A correspondent calls our attention to the appliances of this type furnished by a single firm in the United States, though none of the cranes mentioned is larger than, or even so large as, the Belgian giant. The following are the particulars furnished to us: "The Morgan Engineering Company, of Alliance, Ohio, has an order from the Carnegie Steel Company for three of its patent electric overhead travelling charging cranes, for charging and drawing ingots in the vertical heating furnaces at the Edgar Thomson Steelworks. About a year ago the Morgan Company erected a crane of

Digitized by Google

a similar character at these works. This has been so satisfactory that the firm has determined to change its horizontal heating furnaces to those of the vertical type, and is putting in these three additional charging cranes to handle the entire product of the blooming mill in connection with the rail mills. A 10-ton crane of 60ft. span is also being built for the foundry of this company, making in all 22 Morgan electric cranes in the plant. Two overhead travelling charging cranes, similar to those building for the Carnegie Company, have been ordered by the Ohio Steel Company in addition to a crane of 15 tons capacity, 75ft. span, recently placed, and among other recent orders are a five-ton, 50ft. span, and a three-ton locomotive type crane (both operated by electric motors) for the American Machine Company, Pawtucket; one of 20 tons, 70ft. span, and one of 40 tons, 40ft. span, for Mackintosh, Hemphill, and Co., Pittsburg, making in all seven travelling cranes furnished by that company. Two specially constructed patent travelling cranes for handling blooms in and out of horizontal heating furnaces are being erected for Jones and Laughlins, Pittsburg, in addition to two electric travelling tables for serving their blooming mill. Two travelling tables, operated by electric power, for the blooming mill of the Cambria Iron Company, Johnstown, Pa., will soon be shipped. Recent shipments include a travelling crane of 30 tons capacity, 75ft. span, fitted with double trolleys, to the American Steel Foundry Company, St. Louis; one 20-ton crane supplied with a patent auxiliary hoist, to the United Verde Copper Company, Granite Station, Arizona; one 25-ton, 55ft. span, travelling crane to the Johnson Company, Johnstown, Pa., this being the second furnished the company. It is stated that the Morgan Engineering Company makes applications of electric motors to more machinery of this class than any other similar concern."

The Pacific Cable Question.—In another column we reproduce from the *Times* an article on this subject. In a leading article discussing the matter that paper says: "It has been already shown that, as a matter of fact, the construction of the cable is likely to cost considerably less than the establishment of the new line of steamers which is regarded as being well within the limits of private enterprise. Possibly the tenders for which the Canadian Government has called will establish this fact still more clearly, and, if no other end were served, this alone would be a useful result. But the question opens wider issues. The field of the Pacific is growing daily more important. The Canadian and Australasian colonies have realised this fact, and they are naturally desirous that the ports which belong to them upon its shores should play a leading part in the development of the commercial future. They see also that, as foreign influence increases upon an ocean which separates them from one another, it will become necessary for them to develop their means of inter-communication. The nation which lays the first Pacific cable and puts the first good line of steamships on the Pacific Ocean may reasonably expect to hold a commanding position on its waters, and in the efforts which the British colonies are making to secure this position for Great Britain they are simply obeying the dictates of their own advantage. This is the form of self-interest upon which the principle of Imperial unity is based. It is perhaps both just and wise to leave the initiative in this matter to the communities which are most immediately concerned; but in estimating the advantages of cheaper submarine telegraphy which must inevitably result from the successful establishment of a Pacific cable, especially if it be established under Government control, we should be less than just if we were to underestimate the benefits to be derived by British trade. Nor ought we to permit ourselves to forget that in every political advantage which results from the strengthening of British ties and the development of communication throughout the Empire, a large share must of necessity be ours. For these reasons we are disposed to urge that, when the time is ripe for action, the proposals which have the most practical merit to recommend them may be entertained with an open mind. The possession of one line of cable would not necessarily commit the Government to the wider scheme of the purchase of the whole existing system. On the contrary, the experience of owning one alone for a term of years might possibly be of great value in determining opinion upon the general policy to be hereafter adopted; and, unless the estimates of experts are very widely mistaken, there should be little difficulty in disposing of the line to a private company, if, on the termination of the experiment, such a course were deemed to be desirable."

The Incandescent Lamp in the Future.—This subject is discussed in *L'Industrie Electrique* of August 25 by M. G. Claude, with special reference to the recent communication made by M. Larnaude to the Société Internationale des Electriciens on the subject of incandescent lamps. The writer points out theoretically that for a given temperature the quantity and quality of luminous radiations emitted by a body of determined dimensions depend essentially upon the nature of this body. One has to take as a luminous source a body of which the coefficient of emission is as high as possible. On the other hand, in proportion as we rise in the temperature scale, the proportion of the luminous radiation to the total radiation rapidly increases, as shown by M. Larnaude. Thus from two identical sources, of which one is at a temperature only a little higher than the other, the luminous efficiency of the latter is much superior. It is then necessary to raise the emissive body to as high a temperature as possible. Passing from this standpoint, the writer suggests that it is possible in future that we may be able to utilise for filaments bodies that are not now usable, and which will withstand higher temperatures, as shown by the experiments of M. Moissan. From an industrial point of view, M. Claude asks the reason why central stations use potentials of at most 120 volts, or 240 volts when recourse is had to the three-wire system? Why employ such low voltages, when the immediate result of this fact is to require a system of mains of enormous section and of considerable expense? The writer answers his own questions by stating that the reason lies simply in the fact that the existing incandescent lamp does not allow of our working otherwise, because the carbon being relatively very conductive the filaments that can be obtained for lamps of low luminous intensity would be unable to bear differences of potential exceeding from 100 to 120 volts, unless they are too fragile. Thus there have been made lamps of 16 c.p., and even 10 c.p., with a single filament working at the extreme limit of 200 volts, but these lamps are not practical. It is true that we could without inconvenience in the majority of cases branch the lamps two in series, but this method is generally repudiated. It might be difficult to believe that such a slight cause could bring about this result, but nevertheless that is the exact truth. The actual conditions of manufacturing incandescent lamps are the sole reason of the limitation of lighting distribution. But, M. Claude continues, suppose, on the other hand, that among the new compounds brought to light by M. Moissan there are some, or even only one, which has combined with extreme refractory properties a conductivity two or three times less than that of carbon. Suppose from now it is allowable to obtain practical solid filaments working under 300 or 400 volts, so also from now would the electric lighting industry be

Digitized by Google

revolutionised. The efficiency of the incandescent lamp being raised to much more satisfactory values, central stations would cease to be trammelled by the necessity of laying mains for such a low pressure as at present used, and only have to concern themselves about voltage from the point of view of public safety. It will be from this direction, M. Claude concludes, that progress will be effected in the manufacture of incandescent electric lamps.

Electric Conductors in France.—The French *Journal Officiel* recently reproduced the text of the Bill presented to the Chamber of Deputies by M. Georges Berger in reference to electric conductors in France. It appears that existing legislation in regard to telegraph and telephone lines and electric conductors is contained in enactments of December 27, 1851, July 28, 1885, and May 15, 1888. The scheme submitted by M. Berger has for its object the modernising of this legislation and rendering it more liberal by taking account of the experience gained by the State and by private individuals in the employment of electrical energy. The law of 1851 concerns the monopoly and policy of telegraph lines. The Bill only aims at Article 2 and the clause V. of that law, taking from it its penalties and the forms in which contraventions will be set forth and repressed. The law of 1885 relates to the maintenance and working of telegraph and telegraph lines. It has a special object which is foreign to the question of electric conductors, and the Bill will not alter that law. On the other hand, and this is the main point dealing with the liberty which will be granted to the private use of electricity, the Bill in its last article intends to repeal the decree of May 15, 1888, relating to electric conductors in so far as concerns the previous declaration of their establishment, the general rules on their working, and administrative surveillance. However, the Commission has embodied in the text of Article 2 of the Bill that there must be discussed certain arrangements of the suppressed decree which determine the procedure to be followed by private persons required to ask authority to erect electric conductors. The first article of the Bill states that, apart from public ways, electric conductors not intended for the transmission of signals and speech can be established without authority or declaration. The second clause gives in its first paragraph particulars of the necessary reserves in view of the protection of telephone and telegraph wires, which are generally placed in public thoroughfares, against the inconvenience and trouble that might be caused in their working by the too close proximity of electric conductors, by induction, or by short-circuits. The zone of 10 metres—say 33ft.—which the law will compel to be provided in a horizontal plane from each side of a telegraph or telephone line is strictly necessary to avoid the latter difficulties. The electric conductors referred to are those which serve for the transmission of electrical energy for purposes other than for telephonic and telegraphic purposes. Dealing with the question of conductors for electric tramways, the report states that the Commission have interviewed on the subject the Director-General of Posts and Telegraphs, representing the State and the president of the syndicate of electrical industries, on behalf of the electrical trades. As a result of their deliberations the Commission suggest the introduction in the Bill of a new clause concerning the formation in connection with the Ministry of Commerce, Industry, Post, and Telegraphs of a committee constituted half by professional representatives of the French electrical industries and half by officials of the Post and Telegraph Department, and of members of the scientific world. The electricity committee is to be permanent, and is to investigate all administrative arrangements to be adopted as general regulations, or for each particular case in view of the establishment and working of electric conductors and the conditions of their surveillance.

German Electrical Trade.—In the *Bericht der Aeltesten der Kaufmannschaft über Handel und Industrie von Berlin im Jahre* 1893, Messrs. Siemens and Halske and the Allgemeine Elektricitäts-Gesellschaft give lengthy reports on the condition of the German electrical trade last year. The former state that, as in preceding years, the extension of central electric light stations has been greatly handicapped by the present system of contracting, and by inviting tenders for concessions. As regards the technical part of the industry, the various systems of continuous current, alternating current, and polyphase current have made pretty equal progress. The opposition between rival systems is now less keen than it used to be. Although the establishment of a large central station is now by experience as readily determined as that of the erection of a gasworks or the construction of waterworks, it is really surprising what delays occur and what difficulties are raised before matters are finally decided. During the past year the polyphase system has come into greater use in places where the extent of the district to be lighted is large, as, for instance, in Dresden and Chemnitz. It was feared at one time that the Auer incandescent gas lamp might seriously compete with the electric light, but this has not been the case, but it has had the effect of doing good by helping to show people the advantages of better modes of illumination. The use of current for the transmission of power has extended, and its advantages have been demonstrated in various industries, it being possible to supply the most scattered works with power from one point, and allowing of lighter buildings, the abolition of the belt-holes (which are dangerous in case of fire), of more space in the workshops, etc. Excellent results have been obtained in spinning and weaving mills. Hitherto the most progress has been made in connection with large works, but headway is being made in connection with small industries. The more current which central stations can supply for power purposes the greater is the economy with which they can be worked. Many electric tramways have been opened, but operations in this direction are hindered by the shortness of the concessions granted, which makes the financing of the undertakings difficult; while, on the other hand, objections are raised by the public to the overhead trolley system. As regard prices, the cost of finished raw materials has fallen, but in no proportion to the fall in the finished articles. The Allgemeine Elektricitäts-Gesellschaft report that they were well employed, and that electricity has advanced not only for lighting but for power purposes, especially in the mining, textile, and sugar industries. It is now obvious that electricity is no longer looked upon as an industry of luxury. Small industries are now taking up more power, and in Berlin there were connected with the central station on January 1 last 336 motors of 1,086 h.p., against 150 motors of 520 h.p. a year earlier. The company completed a considerable number of electric tramways during the year, and have many others in progress. The overhead system has proved economical, but one or two scientific bodies are opposed to them. Advances have always been made in connection with steam railway lines, where electricity is being used for lighting railway stations, works, and for carriages, and also for power in works, turn-tables, cranes, etc. The use of multiphase current for transmission of power is making much headway. The price of incandescent lamps has reached the lowest point possible, and as many firms have been selling at a loss, an improvement is to be looked for.

ELECTRIC LIGHT AND POWER.*

BY ARTHUR F. GUY, ASSOC. MEM. INST. ELECTRICAL ENGINEERS.

(All rights reserved.)

TRACTION NOTES.

On first thoughts it may seem strange that, whilst a tramcar is ordinarily run by two horses, a third being generally attached for going up steep gradients, yet an electric tram line has two electromotors in each car, each perhaps capable of developing 12½ b.h.p, or a total of 25 b.h.p. when working at its maximum efficiency. The explanation of this may be traced to two chief facts: first, the great variation of efficiency which electromotors possess for various speeds; second, the undue amount of initial pull or torque required to start the car from rest and to get it up to speed. A horse by exertion can put forth double or treble its normal tractive power for a few seconds, just long enough to start the car and get it under way, as anyone can observe; but when dealing with machines the case is different: they will only give out the maximum power for which they are built—that is, taking their utmost maximum—and with a series motor its useful power is limited by its temperature, and if more than the safe maximum power be drawn from it, it will simply burn up. Hence, in the first place, a motor must exert a very strong torque in order to start the car, and to do this its armature must be built so that it can carry a heavy current for a length of time necessary to get up the speed of the car, perhaps six or eight miles per hour. At the instant of starting, and for three or four seconds afterwards, the motor may have to receive a current ten times the amount it would receive when the car is running at its normal speed on a level track, but although a great amount of power is thus *absorbed* by the motor, yet it *yields* only a small power, because the speed is so slow, the car being just on the move; hence the efficiency of the motor when thus working may be only from 5 to 10 per cent.

In order to calculate out the power requisite for running any vehicle, it is necessary to know the coefficients of friction for various conditions of the road. These coefficients of friction are usually worked out in pounds per ton weight, and for a carriage running on rails about 20lb. per ton may be taken as a fair value. It is very easy to obtain the horse-power necessary to propel a car. Given the weight of the car and the speed; each ton weight of the car signifies 20lb. of resistance, and expressing the speed as feet per minute, then the product of the total resistance and the speed per minute in feet will give the foot-pounds of work requisite to draw the car along at that speed; hence dividing by 33,000 will give the horse-power. For example, suppose we require to find the horse-power necessary to draw a car at eight miles per hour, the weight of the car being 12 tons, and the friction on the rails being 20lb. per ton. When it is stated that the frictional resistance of the car is 20lb. per ton weight, this signifies that pulling or pushing the ton weight on level rails is equivalent to lifting vertically against gravity a weight of 20lb.; hence the total resisting force offered by the car will be 12 × 20 = 240lb. Eight miles per hour = 704ft. per minute, and to exert a pull or force of 240lb. through a distance of 704ft. requires 240 × 704 = 168,960 foot-pounds of work; and since this is done in the space of one minute, hence the power exerted will be 168,960 ÷ 33,000 = 5·12 h.p. This is only for level roads; when there is a gradient to mount, an additional calculation must be made. Suppose that in the above case the car had to travel up an incline of 3 in 100—*i.e.*, every 100ft. produced a rise in elevation of 3ft. — then in 704ft. the rise of level would be 704 × 3 ÷ 100 = 21·12ft. Hence, the car would rise bodily a vertical distance of 21·12ft. when it has travelled 704ft. The weight of the car is 12 tons = 12 × 2,240 = 26,880lb., and 26,880lb. raised 21·12ft. signifies 26,800 × 21·12 = 567,705 foot-pounds of work. This is for one minute, and hence it requires 567,705 ÷ 33,000 = 17 h.p. The power required to run the car along a level is, say, 5 h.p., hence the total power required to run it up an incline of 3 in 100 will be 5 + 17 = 22 h.p.

At the central power station of an electric tram line the power required varies in a most remarkable degree, due to the sudden and irregular load that is thrown on the machinery. This is greatly intensified when the line has a number of steep gradients. At one instant the ammeters may show no current whatever, and the next hundreds of amperes. This extraordinary variation is due to the sudden stopping and starting of cars on the road, and when several cars happen to start at the same moment, then the effect is still more marked. All this variation of load signifies a great strain on the machinery in the generating station, because the engine governors have no time scarcely to act, and at one instant the engines may be working against a very heavy load, and in a second or two afterwards the load may be almost at zero. It is for this reason that nearly all engines in power-houses drive the dynamos by belting, as the belt forms a somewhat elastic connection between the engines and dynamos, and so prevents the great shocks to either that would inevitably occur if there was a rigid connection, as direct coupling.

At the City and South London Electric Railway there are four dynamos, of the Edison-Hopkinson type, each having an output of 450 amperes at 500 volts pressure, and weighing 17 tons. They are driven by link leather belting 28in. wide, a jockey pulley being mounted close by the dynamo to assist the drive. The engines are of vertical compound type, giving 375 i.h.p. each, each engine driving its own dynamo, and running at a speed of 100 revolutions per minute. At the Liverpool Overhead Railway the driving is by ropes, and the engines are horizontal instead of vertical. On both lines the working pressure is 500 volts, constant-pressure system. It is, however, impossible to keep the pressure constant, owing to the enormous fluctuations of current. This pressure is found to be the most suitable for tractive purposes, since it is not too high to be particularly dangerous, and it is sufficiently high to obviate the use of very heavy currents on the line. Nearly all the American tram lines on the overhead trolley system work at 500 volts pressure.

There are, broadly speaking, three systems of electric traction: (1) the conduit system; (2) the storage battery system; (3) the overhead or trolley wire system. So far, no really successful method on the conduit system has been obtained, although numerous attempts have been made to solve the problem. By the "conduit system" is signified the supply of electric energy to the cars by means of an insulated cable positioned in the ground along the track, and making contact with the car motor as it travels along by means of a trailing brush or sliding contact. The supply cable is usually fixed in a conduit or channel, which is flush with the track, a slot being made in the conduit through which the brush makes contact with the supply cable. The fatal objection to this method of making contact is that the slot allows rain and dirt to enter, and so the slot is liable to be filled with water and mud, and thus the insulation of the supply cable is partially, if not wholly, destroyed. The general opinion is that an open conduit, as the slotted conduit is named, can never become a thoroughly reliable method of supplying electric power to electric cars. Numerous attempts have therefore been made to produce a closed conduit, thus obviating the disadvantages of the open conduit, but so far no system has been brought forward that has not some drawbacks to it; and the advent of a perfectly reliable closed-conduit system would go a long way towards promoting the adoption of electric traction on our street tramways.

With regard to propelling cars by the use of storage batteries placed on the car, not very much success has been attained in this direction. The great weight of the batteries as compared with their output, the deterioration of the plates and the rough usage to which they must necessarily be subjected are all great drawbacks. Nothing damages a storage cell so much as to discharge it at a very high rate, and this is precisely what would be required if used to drive electric cars. The sudden starting of the cars, particularly if on a gradient, would in time ruin the cells. Improvements in storage cells are still going on, but they will require to be very much improved before they can be used as a cheap and satisfactory medium for tractive purposes.

The third system—namely, the overhead trolley wire system—has much to commend it. It is in use almost every-

* This forms the concluding extract from a book bearing the above title, which will be published by Messrs. Biggs and Co. early in October.

Digitized by Google

where in the States, and has been adopted in several places in this country: the first being the Roundhay Electric Tramway at Leeds, then on the South Staffordshire tram lines. The only objection that can be made against it is the appearance of a network of wires which span either across the road or half-way across, with the necessary supporting poles. It is possible, however, to make them look very trim, and the wires being thin do not present such a very objectionable appearance, after all. On the other hand, this system of working the cars has been brought to a high state of perfection, and the ease and reliability with which they run more than compensate for any imaginary æsthetic objections.

But perhaps the greatest field for electric traction at present is in the construction of tubular underground electric railways similar to the City and South London Electric Railway. The traffic of a city like London is already so enormous that the streets are almost impassable at times, and the construction of tubular electric railways underneath our main thoroughfares would provide an excellent means of rapid passenger conveyance, and so tend to relieve the congested traffic in the streets.

Cost of Electric Energy.

Within the last few years there has been a considerable decrease in the cost of electric energy. It was not an uncommon thing for a public supply company to charge 1s. per kilowatt-hour, and now the ruling charge is only 6d.; and as time goes on we may certainly look forward to a further reduction. Comparatively speaking, all electric supply companies are so far only on the threshold of their undertakings, and the largest of them does not supply more than 100,000 lamps or so, and this represents a small quantity of light compared to what is supplied by a gas company. The greater the scale upon which electricity is generated the cheaper does it become, and with this fact in view, it is not saying too much to state that there is great probability that we shall in time be able to procure electric energy at a lower rate than at present. Large private establishments can generate their own electricity for this small sum. At present supply companies are burdened by the heavy expense incurred in laying down miles of distributing mains over wide areas, and in return they only supply a small percentage of houses with light; but as the electric light gradually supplants gas, then these mains will become worked at higher efficiency. Another serious obstacle to the low price of electricity is the absence of a day load. For a few hours in the evening the machines are worked at their full load and efficiency; after midnight only a very small load is on; and if winter time, a fair load is obtained in the early morning—the rest of the day is almost unproductive. A foggy day is a source of great revenue to an electric supply company, since the machinery is kept at work all day and evening. It is hoped to remedy this deficiency of load in the daytime by supplying current to electromotors situated in workshops, factories, etc.; then when the day comes to a close and work stops, the power that supplied current to the machines can then supply current for lighting purposes, but at present the supply of current for motive power is extremely small, electromotors not yet having come into general use.

In large private premises, such as mills, business establishments, etc., the use of the electric light has been found to be cheaper than gas—in some cases 50 per cent. as cheap. Where a large amount of steam power is in use, the comparatively small amount taken by a dynamo does not entail much expense, because the steam boilers and engines are used for driving the mill machinery, and 1,000 h.p. is considered nothing out of the ordinary in mill work. Now, 10 per cent. of this power—namely, 100 h.p.—will run, say, 900 lamps of 16 c.p. each—a quantity sufficient to light a fair-sized place. The extra amount of coal and water consumed to produce the necessary amount of electrical energy is only a moderate amount when judged with the amount required to drive the mill machinery.

The attendance required need only be small, and that is limited to the electrical part of the plant, since the care of the boilers and engines is left to the usual mill staff. To put down a special plant in any premises, consisting of motive power in addition to the electrical equipment, is very expensive in first cost or outlay, and it also costs a fair amount to maintain in proper working order, since a stoker and driver, in addition to the dynamo attendant, is required; but even with this heavy expense, in certain large works and establishments it is found cheaper than using gas.

The following details of a gas-engine plant may be interesting, as showing the difference between burning gas direct to produce light and burning it in a gas-engine to produce light by means of electric energy. The data given embody average results extending over a period of six months' run, the figures having been taken by the author while running the plant. The dynamo had an output of 90 amperes at 100 volts, and so was a nine-unit machine; it was driven by one of Crossley's new high-speed gas-engines, F size, guaranteed to work to 14 b.h.p., the engine being fitted with two heavy flywheels, 5ft. 2½in. diameter with face of 8½in. These wheels were weighted near the boss with a large mass of metal, and their large size and high speed gave a great steadiness to the running of the engine. The dynamo was driven by a long heavy link leather belt, the distance between the centres of the engine driving wheel and the dynamo pulley being about 20ft. Owing to the length of drive and weight of belt, the impulses due to the explosions were not transmitted, and the running of the dynamo was as steady as if it were driven by a steam-engine. In a great number of cases, each explosion in the cylinder of a gas-engine produces a momentary flicker or pulsation of the light in the lamps, which is highly objectionable, and by this it is very often easy to tell that the light is produced by a gas-engine plant. In the above case the three things that cured these defects were:

1. The regular running of the engine.
2. The high speed and weight of the two flywheels.
3. The long drive by a heavy belt.

The stored energy in the flywheels prevented the periodic effect of the impulses from being felt. The plant ran for about 10 hours per day, except Sundays. The dynamo having a constant load of 9,000 watts, allowing a loss of 10 per cent. between the engine driving wheel and the dynamo terminals, part of this being due to the belt, the author calculated that fully 14 b.h.p. was developed by the engine. With 60 watts per incandescent lamp, the regular lamp load was about 150 lamps of 16 c.p.; this gives $150 \div 14 = 10{\cdot}7$, or over 10 lamps per brake horse-power of the gas-engine—an excellent performance.

Towards the evening it was found that the load could be slightly increased by adding more lamps, on account of the pressure of the gas being better. The consumption of gas was, over an average of six months, at the rate of 90,000 cubic feet per month, and price was 2s. 9d. per 1,000 cubic feet, so that the cost per month was £12 7s. 6d., or about £150 per annum. This gives the cost of gas alone for one incandescent lamp of 16 c.p. per annum as $150 \div 150 = £1$; 14 b.h.p. for 3,000 hours signifies 42,000 horse-power hours; 90,000 cubic feet per month =, say, 1,080,000 cubic feet per annum, and 1,080,000 divided by 42,000 gives us 25·75, or $25\frac{3}{4}$ cubic feet of gas consumed by the gas-engine per brake horse-power. A 14-c.p. gas jet takes about five cubic feet per hour, therefore $25\frac{3}{4}$ cubic feet would yield a fraction over five gas jets, or a total illuminating power of $5 \times 14 = 70$ c.p., but this same $25\frac{3}{4}$ cubic feet of gas, if put into a gas-engine and burnt, and allowed to do work by driving a dynamo, will give 1 b.h.p., or sufficient electrical energy to run $10\frac{1}{2}$ incandescent lamps of 16 c.p. each, or a total illuminating power of $10\frac{1}{2} \times 16 = 168$ c.p., so that when burnt in a gas-engine a certain quantity of gas will yield more than twice as much (or as 168 : 70) illuminating power than if it were burnt direct in a gas jet. Putting this in another way, gas burnt from a gas jet only gives 41 per cent. of the light that would be given when burnt in a gas-engine to produce electricity.

Telephony in Germany.—The telephone system between Berlin, Posen, Dantzic, and Elbing is to be extended to Königsberg, and afterwards to Memel, *viâ* Tilsit. Telephonic communication is to be established between Berlin and Vienna, *viâ* Dresden, by November. The charge for a message is to be 1s. 6d.

LESSONS OF THE RICHMOND ELECTRIC RAILWAY.

BY FRANK J. SPRAGUE.

The year 1887 marked an epoch in one of the most important of modern industrial revolutions, and, curiously enough, a city in the southern United States was the place selected—largely by chance—for northern capital and enterprise to carry out a grave experiment. Scarcely seven years ago those enthusiastic pioneers who—poor in pocket and struggling against unbelief and ridicule, yet confident in the ultimate outcome of their endeavours—proclaimed the future success of electric railways, surely had little enough in the way of practical results on which to base their prophecies. There were altogether perhaps a dozen electric railways of various types in existence; none was so satisfactory as to warrant general adoption, and all were handicapped by their special experimental character. Capitalists, car builders, railway officials, engineers offered no encouragement; electricians themselves were in the main doubtful. The electric motor was limited in its applications. It was looked upon as a piece of complicated machinery to be carefully housed and suspiciously watched. It was hydrophobic in character, eccentric in operation. Its construction was crude, its design unsatisfactory, its functions more or less mysterious. The vagaries of the electric current were many, its evasiveness surprising.

When it was proposed to use this agent to overturn the existing tramway systems of the United States—to put a motor under a car, exposed to dust, moisture, and all the evils of negligent treatment, there were thought to be good grounds for insanity. To connect it to the wheel by gearing was to violate the laws of mechanics. To govern two or more such machines out of sight was "playing" a lottery. To tempt a wayward current of comparatively high pressure by using the ground as a return was enough to disturb the ghost of Ben Franklin. The ordinary conditions of a street car service were pronounced an insuperable obstacle to any self-propelled car; a greater than 6 per cent. grade was declared to be prohibitory. The investment of copper for a multiple-arc system of supply was financially forbidden. Four hundred and fifty volts potential threatened unknown terrors of torture and death, and a bare overhead wire promised innumerable holocausts. Even nature, with its mud, snow, and ice, was to rise in rebellion.

Such was the condition of affairs when, in the spring of 1887, a contract was made between the capitalists representing the Union City Railway of Richmond, Virginia, and the Sprague Electric Railway and Motor Company, of New York City. This contract was unique. It called for the completion in 90 days of the equipment of a road at that time unlaid, and with a route determined only in part. It provided for a complete steam and electric plant of 375 h.p. capacity, the furnishing of 40 cars with 80 motors and all appurtenances necessary for their operation, and a complete overhead system. Thirty of the cars were to be operated at one time, and grades as high as 8 per cent. to be ascended. The price for the equipment was 110,000dol., to be paid in cash after 60 days' "satisfactory" operation.

At the time of taking the contract, the Sprague Company had only a blue print of a railroad machine and some experimental motors used on the elevated road. The hundred and one details essential to success were undetermined. Such a contract is one which no business man would ordinarily assume, especially in view of the entirely unprepared state of the company. It was justified by subsequent events because of the pioneer character of the work. Considering all the difficulties which confronted the company, it is probable that, had they been known beforehand and the solution of them unforeseen, this contract would never have been made. Fortunately for the future of electric railways, the difficulties could not all be foretold, and did not have to be met simultaneously. The road cost before completion not less than 160,000dol., and only 45,000dol. was paid in cash, with a like amount in bonds. Enormous as this expense was, as grave the risks, the results have entirely justified them all, for the Richmond road stands as the prototype in almost every essential detail of the modern electric trolley system. There was met every difficulty which could be encountered in an overhead system on heavy grades and with sharp curves, and there was settled for all time the question of the economical operation of a large system of street railways by methods of direct supply.

The limits of this article prohibit more than a reference to the essential features of the new system, the special characteristics of the road, and some personal reminiscences of its development. Briefly speaking, the equipment was what is known as a single overhead trolley system with ground return. The current was distributed by feeders to certain central points from which it was taken by a main conductor extending the entire length of the road, it feeding in turn at intervals of about 1,000ft. a working conductor of constant size, ½in. diameter, of hard-drawn silicon wire, known technically as the "trolley" wire. From this the current was taken by an under-running trolley with upper-pressure contact carried in the middle of the car and having a universally flexible movement. Thence it was carried to the controlling switches on each platform, arranged to control the motors in series or multiple and to make the necessary changes in the field circuits.

The motors, of which there were two, were each centred on a driving axle, directly geared to it with single reduction, and flexibly supported at the free end, so as to allow perfect freedom of movement of the machine while maintaining parallelism between the axes of the car axle and the motor shaft. Fixed brushes were used on the commutators for forward and back motion. The current, after passing through the motors, went by way of the wheels into the track and thence, partly by the track, the rails of which were connected together and likewise reinforced by a continuous wire, and partly by the earth and the water-pipes and gas-pipes to which the rail system was connected at various points by earth-plates sunk in deep wells, back to the central station. The main features are those which are common to every trolley systems of to-day. Some of them, more particularly those relating to motor mounting, had been shown in 1886 in an experimental equipment on the Thirty-fourth-street branch of the elevated railroad in New York City, on some individual cars used for storage battery tests in New York, Philadelphia, and Boston, and on the initial equipment of the Union passenger railway of St. Joseph, Missouri, which contract slightly preceded that of Richmond, but generally they saw their first application on a commercial scale in the latter city.

A brief inspection of this road and the curve and grade characteristics will give some idea of the difficulties to be overcome, but these formed only a part, and it is fortunate that in the development of this road the writer had the assistance of two young officers—Lieutenant Crosby, a graduate of West Point, and Ensign S. Dana Greene, of Annapolis (which was my own *alma mater*)—who, though entirely inexperienced in electric street railway work, had energy, pluck, and endurance. It needed all the advantages of youth and enthusiasm, as well as a high technical training, to carry the work through to a successful end. Their work was largely supplemented by that of a number of men who, though not trained engineers, and under adverse conditions and with many hardships, faithfully worked for victory.

Our contract was made in May, and in July I was laid up with an attack of typhoid fever, which, with my period of convalescence, kept me away for nine weeks, leaving almost the entire burden on those who were associated with me. Returning to duty about October 1, I hastened to Richmond to go over the route and note the condition of the work. Up to that time I had never seen the road. Much of the trackwork had been finished, poles had been set, some of the machines constructed, the central station was well under way, and considerable experimental work was in hand. The owners of the road were clamorous to begin operations, while the excuses on our part were without number. I shall never forget the feeling I had when, returning from the improvised car-shed, I stopped at the foot of Franklin-street hill. As I looked up this incline under the bridge connecting the Ballard and Exchange Hotels, and saw a grade varying from 4 to 10 per cent. rising above the bridge, I was for a moment doubtful of the outcome, and I began to realise the difficulties, not

Digitized by Google

only those pertinent to our own work, but others forced on us by the unusual and unforeseen conditions under which we had undertaken it.

The track was simply execrable, laid for profit, not for permanence, and with no adequate idea of the necessities. It was a flat 27lb. tram rail of antiquated shape, poorly jointed, unevenly laid in red clay, and insecurely tied together. The total trackage was about 12 miles; it ran in the most irregular way over about nine miles of streets. Part was double and part was single track, a part laid on paved streets, but the larger balance on macadam or unpaved streets. There were 29 curves, five being of less than 30ft. radius. On these sharp curves were grades as high as 8 per cent. There were straight grades as high as 10 per cent. The outer rails were often inches below the inner ones, and the whole track at times would disappear into the red clay, which froze over it, and stuck with remarkable tenacity. As I have said, the sight of the main grade was one of my most unpleasant sensations. There were two things which seemed probable. The first was that the car, for lack of track adhesion, would not ascend the grade at all, no matter how powerful the machines, and the second was that I knew the latter were lacking in capacity.

Our first machines had been built with one reduction of gearing, to which all street railway practice is now gravitating. An 8 per cent. grade would strain them, and a 10 per cent. grade was probably fatal. Hastening back to New York we held a consultation as to what should be done. The easiest way out of the difficulty seemed to be to run on heavy grades with a cable operated by electric motors in pits sunk beneath the track—a feasible plan if the car could not by its own adhesion mount a 10 per cent. grade; on the other hand, if it did have sufficient adhesion, then a change in the machines was necessary. The most direct thing which suggested itself was the introduction of an intermediate gear, and, as it was constructed, this proved to be a most serious problem.

Before deciding upon this, the laconic advice of the president of the company, Mr. E. H. Johnson, was "to find out whether the car can get up the grade at all"; this advice was sound enough, and I returned to Richmond to try the experiment. The first test was when we stopped in the middle of a sharp curve with the car apparently locked. I told the manager, Mr. George Burt, formerly of the Panama Railway Company, that I would pull the car out of the curve if it wrecked the machines, and when called upon they responded nobly. This was a very convincing experiment to him, although not entirely so to me, because it did not settle the question of track-adhesion. Having got out of our temporary difficulty, we made a run to the foot of the Franklin-street hill, our course being distinguished by a free fight, in which an eccentric inhabitant, somewhat the worse for liquor and politically excited, nearly cleaned out our party, until one or two of our best fighting men got into trim, after which we proceeded peaceably.

Arriving at the foot of the hill we stopped to survey the enemy. When I expressed doubt of the ability of the machines to make the ascent, Burt said: "If you can get out of such a curve as that we just left, you can go up the side of a wall." I knew that even if we succeeded the machines would probably be wrecked, but there was nothing to do but to try it, so, putting on the current, we steadily climbed up this hill, then another, and another around several curves, finally reaching the highest point in the heart of the city. By this time the machines were boiling hot, and we stopped in the centre of an admiring crowd in the hope that they would cool down so as to allow us to proceed. No sooner had we started than there was a peculiar movement, then strange, but afterwards very familiar, due to a crossed armature, and I knew that we were disabled. We ran on for a block in our crippled condition, surrounded by a howling mob who seemed bent on taking possession. Not caring to confess serious trouble, I told Greene in a tone so that I was generally heard that there was some slight disarrangement of the circuits, that he had better go and get his instruments; meanwhile I put out the lights and stretched out in the bottom of the car for a rest. The crowd dispersed, and after a long time Greene returned with his "instruments"—four big powerful mules, at that moment the most effective we could get. We soon began our retrograde journey, at first with the mules in the rear, because by cutting out one machine, I hoped to get back with the other. Being on the wrong track, and with severe grades and curve, I knew it to be a doubtful feat. On approaching one of them on a slight down grade I shouted for everyone to jump and give the car a push, put on the full current, and before I could realise it the car had left the curve and run into the foundation-stones of a hotel. There was no question this time about our being disabled, and we had reluctantly to turn to our mules for assistance. This is but one of many similar night experiences, but, despite our damaged condition, we had settled once for all one problem, and that was that with all the weight of the car used for traction, a 10 per cent. grade could be ascended; but having settled this, we were face to face with the necessity of introducing an intermediate gear with a distance between the armature shaft and car axle of only 12½in. on machines entirely unprepared for any such change. Hastening back to New York it occurred to me to put a stud on one end of the machine carrying a gear and a pinion of smaller size, into the former of which the armature pinion should mesh, while the latter should engage the teeth of an internally-split gear on the car axle. It was a happy thought, for the strain on the stud was largely removed because the moments were equal and opposite on one side. Hastening to the Brown and Sharpe Manufacturing Company, in Providence, R.I., I laid my difficulties before them, representing how vital every day's delay was to me, and gave orders that so far as it was possible, night and day, without regard to expense, they should get out a set of tools and jigs which would permit us to alter our machines in Richmond, and at the same time to make the necessary patterns and to cast the requisite gears. Their response was prompt, and in a few weeks we had removed all our machines, taken them apart, changed them over, introduced the new gears, and they were again ready for running.

Troubles with gear reduction, serious as they were, formed only a small part of our difficulties. Field magnets, hastily wound in sections with crude insulation, frequently grounded and crossed. The armatures had a commutator on each end, and were so connected as to bring the brushes at each end on top for easy inspection. Our overhead work was most unsatisfactory. No less than from 50 to 60 designs of trolleys of almost every conceivable shape and character had been brought out. The work of mounting the machines and changing them was conducted practically out-of-doors, subject to all the inclemencies of a wet Richmond winter.

Into the details of all the work I cannot enter here, but by the end of January the time had come when it was vital for us to start. The owners of the road, taking advantage of our difficulties and naturally disappointed and alarmed, threatened to cancel the contact and forced us to grave concessions. Meanwhile every man had been under intense strain; day and night work was the rule. Everything made under this pressure cost vastly more than under any other condition. Changes were frequent, decided upon almost instantly because of the necessity of doing something, and hence without careful deliberation. The road must be made to go; it meant financial ruin for many unless it did. To the railway development its failure would prove a most serious blow. My own reputation and future career, as well as that of my associates, seemed blasted if failure marked the Richmond road.

About the end of the month we prepared to open the road with 10 cars. At this time matters were going more smoothly, the overhead work had been gotten into fair condition, the central station was all right. The new gearing was apparently a success, many of the difficulties with machines and switches had been overcome. As a preliminary we spent a day carrying the children of the town, and on February 8, 1888, in a drizzling rain, we opened the line for regular service. The day was one of disappointment. The cars, crowded with passengers, would one after another suddenly stop in the street and refuse to move, or to be moved, because of locked gears.

Digitized by Google

A man would go under the car, take off one gear, and continue, if possible, with the other machine, or bodily haul the car off the track so that another could go by. Opinions as to the difficulty were not agreed, but one reliable man, Pat O'Shaughnessy, who has been engaged at work with me for many years, and who is possessed of a most happy mechanical judgment, speedily detected the trouble and was not long in finding the remedy.

Of all the difficulties met, one of the most exasperating was that connected with running with fixed brushes. For a long time it seemed almost as if this would prove a failure. The armatures were continually grounding or crossing, and one of the commutators was particularly badly burned, the mica itself being charred and the copper blistered. After a time we found that this was largely due to the fact that the current always went into one brush and out at the other, and then we adopted the practice of reversing the armature circuits instead of the fields for a change in direction.

It seemed, however, that we had no copper commutator good enough, and there followed a change of every commutator on the road. Not only special forms of commutators were made, but special materials were made in various places. Before the final adoption of carbon, the variety of brushes tried was without number; sometimes flat ones, solid and laminated, which would wear through, double over and hug an arc of the commutator, or oblique, solid, and laminated brushes which would catch in the bars, reverse or split, and straddle the commutators, with the direct result of ruin to commutators, crossed armatures, and burned-out fields. It was a daily occurrence to see a loaded car climb a grade with a lurid green glare lighting up the track, but with no possibility of getting at it, although I knew that 100dol. worth of damage would be the result of the trip. Then we tried tilting brushes and variously-shaped pieces of copper, bronze, and brass set on end, and pressed down by all sorts of springs, and finally solid bars of brass set on end.

About this time 9dol. worth of brass per day, milled off by the rough bars of the commutator, lined the track with a glittering path; not a single trip was made without inspection, with generally a change of brushes or some other repair. But this was not all. Every armature was unwound, the bodies shortened, and then rewound. Disabled armatures were numberless, and to keep the road in operation tons of machinery were shipped by express. Frequent change of parts were necessary, and since the machines had not been built on the interchangeable principle, in a few weeks they were of the most heterogeneous character.

We managed, however, to keep the cars going, and gradually we saw our difficulties lessening, although new ones would crop up, and little by little the number of cars in operation was increased from 10 to 20, then to 30, and finally one of our most reliable men, David Mason, put 40 cars into operation, or 10 more than the station or line equipment called for. In the three months of operation from February until May, 1888, despite innumerable changes and troubles inconceivable, no car in Richmond was pulled a foot by animal power, for if any accident occurred to a motor the car went along with the crippled machine or with one good one, oftentimes with the heaviest loads and on the sharpest grades, and in some cases in tow of another car. One hundred and forty men, often with only a day's training, were soon broken in to handle the various parts of the system.

Saturday, May 4, was a red-letter day in our calendar. On that day, in the afternoon, when traffic was heavy, we put on 10 additional open cars, finally banking them up near the western terminus. Just at dusk 11 cars at close headway were run at full speed down one of the principal streets, and an hour later 30 cars, many of them heavily loaded, were in full operation. Three boilers rated at 375 h.p. supplied not only to the railroad dynamos, but lighting dynamos with an equivalent load of over 1,000 lamps.

The highest reading on the line was less than three-quarters of the normal capacity of the dynamos, and the average reading only one-half. This test settled conclusively all question as to distance, speed, and power, and practically ended the discussion as to the merits of the series and multiple arc systems of distribution. Fatigue, worry, and expense were all forgotten for the moment, such was the keenness of enjoyment in an assured victory. Subsequently one of the most beautiful sights that I had witnessed for a long time was the assembling of 16 cars in the centre of the town at night by reason of a mistake in the time of ending of an entertainment. This, too, was a most important demonstration upon the public mind of the possibilities in the line of work we were pursuing.

Another important experiment in banking cars occurred on the occasion of the visit to Richmond of president Henry M. Whitney and a number of the directors of the West End Railroad of Boston, then seriously considering the adoption of the cable system. For lack of better shelter the cars were banked out of doors at the eastern terminus. On this particular night 22 cars were so collected.

General-Manager Longstreet, of the West End road, having expressed doubts as to the handling of the cars electrically when bunched together, Burt and I made up our minds we would settle the question by a critical experiment, although it was overtaxing the line many times over. Mr. Whitney had retired, but on receiving word about midnight that we were willing to make such an experiment, he immediately arose, and we were soon on our way to the eastern sheds, two miles from the station. The current supply was by two paths over a silicon bronze wire $\frac{1}{4}$in. diameter, reinforced by another wire of about the same size. We loaded the feeder safety catches, raised the pressure to 500 volts, and ordered the engineer to hold the machines to duty no matter what happened. At the wave of a lantern, 22 motormen as quickly as possible started their cars at the termination of a line calculated for only four distributed cars. The potential dropped to 200 volts, then gradually rose, and soon all the cars were running out of reach of signals. This settled the cable question for Boston, and we shortly secured the contract for the first overhead line in that city.

Richmond was prolific in new experiences, which in variety and extent taxed our resources to a degree happily unknown on modern roads. Many were not inherent to the machines or the system, but were caused or augmented by local conditions. One of the most annoying was the jumping of the cars from the track. As has been stated, this was not only largely laid in dirt streets, the soil of which was of red or yellow clay, but the curves had only one guard-rail, and were not bound in by paving. The winter months brought frequent and heavy rains, the cars were large and heavy, and in a short time the curves spread. Mud and stones would get into the grooves, and on account of the tangential tendency of the cars, before an inexperienced man could check them they were off the track and the wheels were down several inches in the mud alongside the stringer pieces, and the track brakes hard fast.

For some time scarcely a trip was made without the cars jumping the track, and a heroic treatment was at first adopted which gave them the appearance of battering-rams. Twelve-foot sticks of timber and scaling-ladders were carried under the car bodies, and when a car left the rails and tried to bury itself in the mud, all hands, often aided by the passengers, pried it back into place. Gradually the soft places were filled up with cinders, the track rectified, the curves paved, and we soon learned to get a car back by using track plates and completing the ground circuit by a flexible cable which we termed an "electric kedge."

The bugbears of sleet, snow, and mud were frequently raised; it was impossible to keep the tracks from being thickly covered by the crowding of the passing vehicles, and when a sharp change of weather occurred at night the cars in the morning would play leapfrog with brilliant pyrotechnic displays. Virginia mud clung hard to cold iron, and it was a common thing to have to cut through clay, snow, and ice when the tracks were completely out of sight.

On one of the worst nights of winter I had gone to bed completely played out after a vain attempt to get the "Snowflake," our construction car, up a 6 per cent. grade on a slippery track with one motor, and had finally left it in the street for the morning's work. Dawn brought dis

Digitized by Google

may, for tracks, trees, and trolley wire were covered with a heavy sleet. Not a car was in operation, and everything looked hopeless. In desperation I boarded my pet car, swept off some of the snow, wiped off the motors so that there was only a moderate display of leaks, and started to make the best of my way to the power-house. The sun had come out, water was dripping from the pendant icicles, and when I turned the corner at the head of the Franklin-street grade my astonished eyes were gladdened by the sight of a car slowly climbing the 10 per cent. grade, with Pat on top pounding the trolley wires with a broom and making the sleet drop off in great lengths. That settled the sleet question, and we gave ourselves no more concern on that account.

Thunderstorms are particularly severe in Richmond, and this brought us new anxieties. The length of the overhead circuit, the unguarded condition of the wires, and the numerous ground connections offered by lamps and motors invited frequent discharges. We awaited the result of the first attack of the heavens with interest. Like many other anticipated troubles, so far as they related to danger to life, our apprehensions were quickly allayed.

In one of the first storms lamps were broken, field magnets grounded, and switches burned out. On one occasion three men were sitting on the rear platform, one with his legs probably dangling over the switch, when there was a sharp flash and a loud clap, accompanied by a peculiar report in the switch beneath him where the discharge jumped to earth. Three terrified darkies disappearing as fast as their legs could carry them up the street was the sequel. As a rule, however, little personal difficulty was experienced because of this trouble. Passengers often did not know when the lightning discharged through the car circuits, or, if they did, they quickly got used to it.

We found that the lamp circuits offered a very free path, so when a thunderstorm appeared, the lamps, ostensibly to light the car, as was carefully explained to timid lady passengers, were turned on and the lightning given free play. The armatures, being on the ground side of the circuit, were rarely injured because the fields acted as choking coils and forced the discharge to earth at some weak point. Lightning arresters without number and with varying degree of success were introduced, but the lightning always remained more or less erratic.

Such are some of the reminiscences of Richmond days. The infant industry of seven years ago has grown to manhood and marks one of the most important of modern industrial advances. Six hundred railroads, 25,000 motors, and an investment of a quarter of a billion of dollars speak of its marvellous growth. The days of the horse car are limited. The cable is restricted to special localities. In suburban service already the electric car rivals the locomotive, and the latter is being gradually forced to its legitimate field of through trunk-line and freight service.—*Engineering Magazine.*

PRACTICAL NOTES ON DYNAMO CALCULATION.*

X.

BY ALFRED E. WIENER.

(Continued from page 252.)

21. *Running Value of Armature.*—In order to form an idea of the efficiency of an armature as an inductor, its "running value" has to be determined. In forming the quotient of the total energy induced by the product of the weight of copper on the armature and the field density, the number of watts generated per pound of copper at unit field density is obtained, an expression which indicates the relative inducing power of the armature:

$$\rho = \frac{E \times C}{lb_a \times \frac{\mathfrak{B}}{20{,}000}} = 20{,}000 \times \frac{E \times C}{lb_a \times \mathfrak{B}} \quad . \quad (54)$$

ρ = running value of armature in watts per pound of copper, at unit field density (20,000 lines of force per square inch);
E = total E.M.F., generated in armature, in volts;
C = total current, generated in armature, in amperes;
lb_a = weight of copper in armature, in pounds, formula (28);
$\mathfrak{B}$ = field density, in lines of force per square inch.

The value of ρ for a newly-designed armature being found, its relative inductor efficiency can then be judged at by comparison with other machines. The running value of modern dynamos, according to the kind of armature, varies between very wide limits, and the following are the averages:

TABLE XXXIII.—Running Values of Various Kinds of Armatures.

Kind of machine.		Kind of armature.	Running value. (Watts per lb. of copper at 20,000 lines per sq. in.)
High speed ..	Bipolar	Drum	300 to 600
		Ring	200 ,, 400
	Multipolar...	Drum	200 ,, 400
		Ring	150 ,, 300
Slow speed ...	Bipolar	Drum	150 ,, 300
		Ring	100 ,, 200
	Multipolar...	Drum	100 ,, 200
		Ring	75 ,, 150

22. *Armature Torque.*—The work done by the armature of a dynamo can be expressed in two ways: electrically, as the product of E.M.F. and current strength,

$$W = E \times C \text{ watts};$$

and mechanically, as the product of circumferential speed and turning moment, or torque,

$$W = 2\pi \times N \times T \times \frac{746}{33{,}000} = \cdot 142 \times N \times T \text{ watts};$$

W = total energy developed by machine, in watts;
E = total E.M.F. generated in armature, in volts;
C = total current generated in armature, in amperes;
N = speed, in revolutions per minute;
T = torque in foot-pounds.

Equating the above two expressions, we obtain:

$$E \times C = \cdot 142 \times N \times T,$$

from which follows:

$$T = \frac{E \times C}{\cdot 142 \times N} = 7 \cdot 042 \times \frac{E \times C}{N} \text{ foot-pounds} \quad . \quad (55)$$

But the E.M.F. generated in an armature can be expressed, compare formula (51), by:

$$E = \frac{K \times \Phi \times N}{P \times 10^8 \times 60},$$

hence: $$T = 7\,042 \times \frac{K \times \Phi \times N}{P \times 10^8 \times 60} \times \frac{C}{N}$$

$$= \frac{11 \cdot 74}{10^{10}} \times \frac{C}{P} \times K \times \Phi \text{ foot-pounds} \quad . \quad (56)$$

From this follows that in a given machine the torque depends in nowise upon the speed, but only upon the current flowing through the armature, and upon the magnetic flux.

23. *Peripheral Force of Armature Conductors.*—By means of the armature torque we can now calculate the drag of the armature conductors in a generator, respectively the pull exerted by the armature conductors in a motor.

The torque divided by the mean radius of the armature winding, in feet, gives the total peripheral force acting on the armature; and the latter, divided by the number of effective conductors, gives the peripheral force acting on each armature conductor:

$$t_p = \frac{T}{\frac{\frac{1}{2}d_a'}{12} \times K \times \beta'} = \frac{24 \times T}{d_a' \times K \times \beta'} \text{ pounds.}$$

Inserting in this equation the value of T from formula (55), we obtain:

$$f_p = \frac{24 \times 7\,042 \times \frac{E \times C}{N}}{d_a' \times K \times \beta'}$$

$$= \frac{2 \times 7 \cdot 042 \times \pi}{60} \times \frac{E \times C}{\left(\frac{N}{60} \times \frac{d_a' \times \pi}{12}\right) \times K \times \beta'}$$

or $$f_p = \cdot 7375 \times \frac{E \times C}{S \times K + \beta'} \text{ pounds} \quad . \quad (57)$$

* From the *Electrical World* (New York).

Digitized by Google

f_p = peripheral force, per armature conductor, in pounds;
E × C = total output of armature in watts;
S = mean conductor velocity, in feet per minute;
K = total number of armature conductors;
β' = percentage of effective armature conductors, see Table XXXII.

A second expression of the peripheral force can be obtained by substituting in the original equation for f_p' the value of T, from formula (56), thus:

$$f_p = \frac{24 \times 11{\cdot}74}{10^{10}} \times \frac{C}{P} \times \frac{K}{K \times \beta'} \times \frac{\Phi}{d_a'},$$

$$= \frac{2{\cdot}82}{10^8} \times \frac{C \times \Phi}{P \times d_a' \times \beta'} \text{ pounds} \quad (58)$$

Replacing in this the total useful flux, Φ, by its equivalent, the product of gap area and field density, we find a third formula:

$$f_p \times \frac{2{\cdot}82}{10^8} \times \frac{C \times d_a' \times \frac{\pi}{2} \times \beta' \times l_a \times \mathfrak{B}}{P \times d_a' \times \beta'}$$

$$= \frac{4{\cdot}43}{10^8} \times \frac{C}{P} \times l_a \times \mathfrak{B} \quad . \quad (59)$$

f_p = peripheral force, per armature conductor, in pounds;
$\frac{C}{2P}$ = total current flowing through each armature conductor, in amperes;
l_a = length of armature core in inches;
$\mathfrak{B}$ = field density, in lines of force per square inch.

It is on account of this peripheral force exerted by the magnetic field upon the armature conductors that there is need of a good positive method of conveying the driving power from the shaft to the conductors, or *vice versâ*; in the generator it is the conductors and not the core discs that have to be driven; in the motor it is they that drive the shaft. Thus the construction of the armature is aggravated by the condition that, while the copper conductors must be mechanically connected to the shaft in the most positive way, yet they must be electrically insulated from all metallic parts of the core. In drum armatures the centrifugal force still more complicates matters in tending to lift the conductors from the core; it has therefore been found necesary to employ driving horns, which either are inserted into nicks in the periphery of the discs, or are supported from hubs keyed to the armature shaft at each end of the core. In ring armatures the centrifugal force presses the conductors at the inner circumference towards the armature core, and thus helps to drive, while the spider arms, by interlocking into the armature winding, serve as driving horns. If toothed discs are used, no better means of driving can be desired.

24. *Armature Thrust.*—If the field frame of a dynamo is not symmetrical, which is particularly the case in most of the bipolar types (see Figs 22 to 31), unless special precautions are taken there will be a denser magnetic field at one side of the armature than at the other, and an attractive force will be exerted upon the armature, resulting in an armature thrust toward the side of the denser field.

The force with which the armature would be attracted, if only one-half of the field were acting, in absolute (C.G.S.) units, is:

$$f_1' = 2\pi \times \frac{G'}{2} \times \left(\frac{\mathfrak{B}_1'}{4\pi}\right)^2 = G' \times \frac{\mathfrak{B}^{12}}{16\pi} \text{ dynes};$$

G' = gap area, in square centimetres;
$\mathfrak{B}_1'$ = field density, in lines of force per cm.²

Or, in English measure, one square inch being equal to 6·45cm.², and 1lb. equal to 444,980 dynes,

$$f_1 = \frac{6{\cdot}45 \times G \times \left(\frac{\mathfrak{B}_1'}{6{\cdot}45}\right)^2}{16\pi \times 444{,}980} = 7 \times 10^{-9} \times G \times \mathfrak{B}_1^2 \text{ pounds} \quad (60)$$

G = gap area, in square inches;
$\mathfrak{B}_1$ = field density, in lines of force per square inch.

Expressing the gap area, G, by the dimensions of the armature, we obtain;

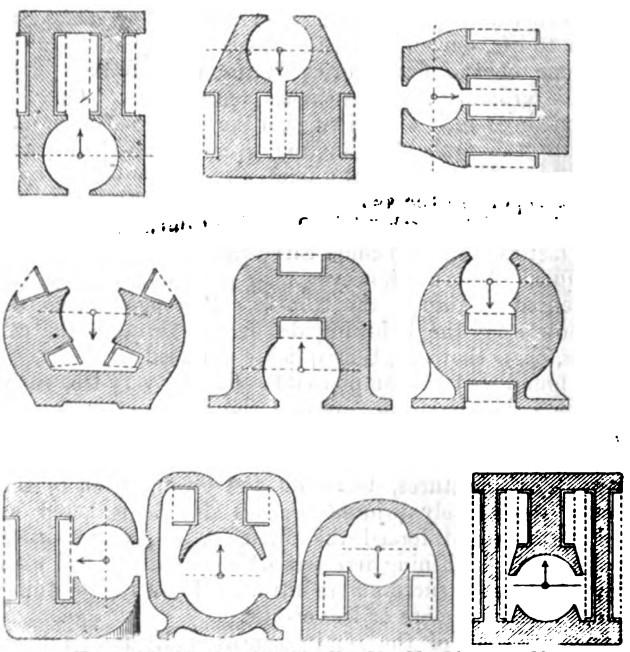
$$f_1 = 7 \times 10^{-9} \times \frac{d_a \times \pi}{2} \times l_a \times \beta' \times \mathfrak{B}_1^2$$

$$= 11 \times 10^{-9} \times d_a \times l_a \times \beta' \times \mathfrak{B}_1^2 \text{ pounds} \quad (61)$$

If, now, both halves of the field are in action, but one half is stronger than the other, the armature will be drawn towards the stronger side by the amount of the difference of their attractive forces. The armature thrust, therefore, is:

$$f_a = f_1 - f_2 = 11 \times 10^{-9} \times d_a \times l_a \times \beta' \times (\mathfrak{B}_1^2 - \mathfrak{B}_2^2) \text{ lbs.} \quad (62)$$

f_a = attracting force acting on armature, due to unsymmetrical field, or armature thrust, in pounds;
d_a = diameter of armature core, in inches;
l_a = length of armature core, in inches;
β' = percentage of effective gap circumference, see Table XXXII.;
$\mathfrak{B}_1$ = density of field, on stronger side, in lines of force per square inch;
$\mathfrak{B}_2$ = density of field, on weaker side, in lines of force per square inch.



FIGS. 22, 23, 24, 25, 26, 27, 28, 29, 30, AND 31.

In such types where the attracting force of the field manifests itself as a downward thrust, as in those shown in Figs. 23, 25, 27, and 30, the value obtained by (62) is to be added to the dead-weight of the armature, in order to obtain the total down thrust upon the bearings. If, however, f_a is an upward thrust, as is indicated in Figs. 22, 26, 29, and 31, the down thrust upon the bearings is the weight of the armature diminished by the amount of f_a. In the cases illustrated by Figs. 24 and 28, the action of the field causes a sideward thrust, which has to be taken care of by a proper design of the bearing pedestals or of the journal brackets.

(To be continued.)

THE ELECTRIC LAUNCH "APHRODITE."

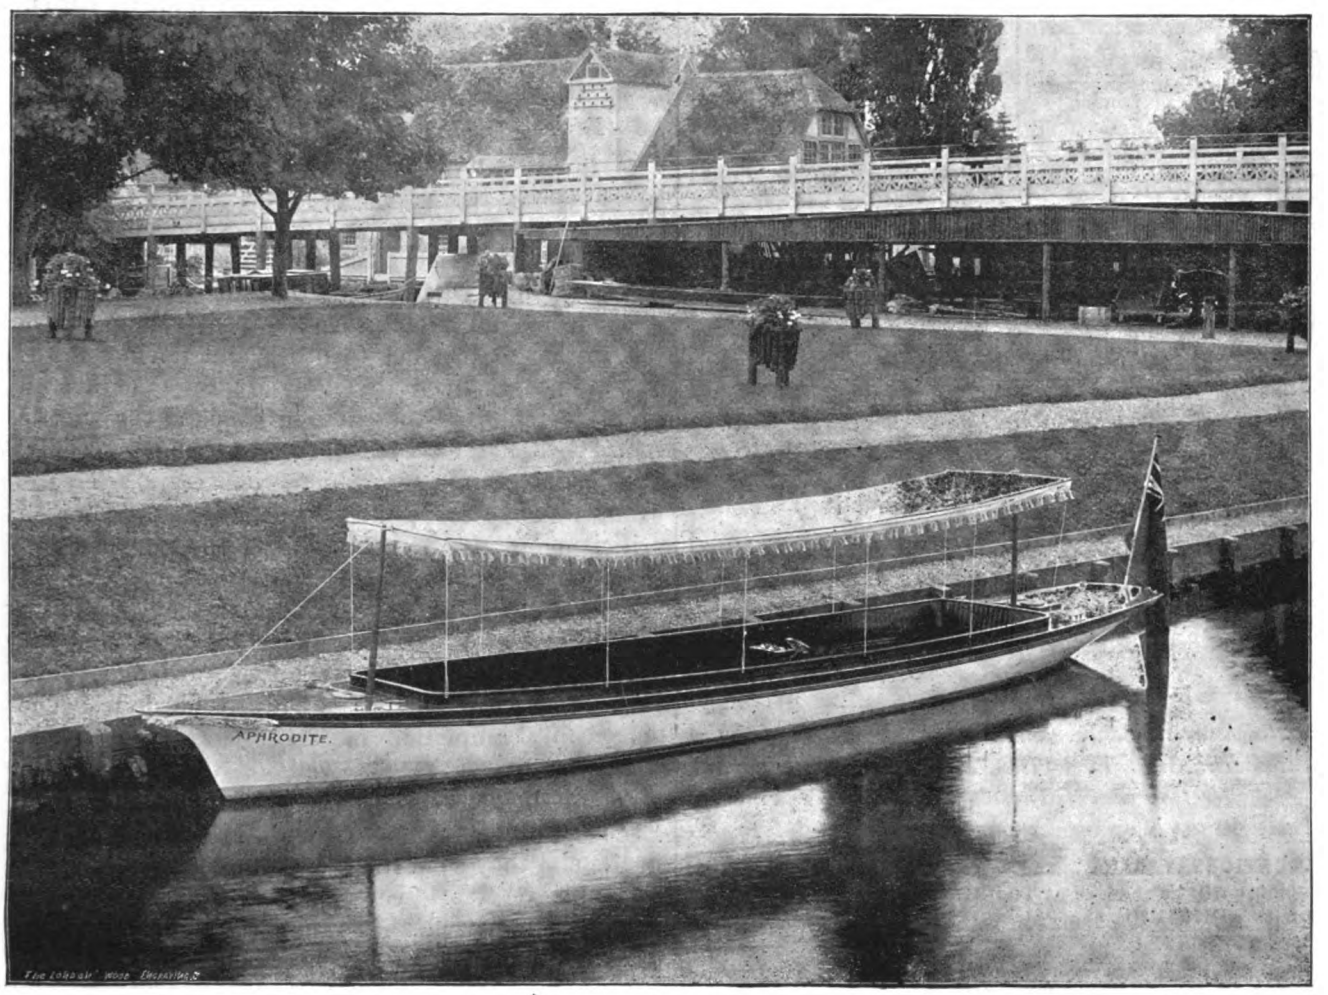
In the *Electrical Engineer* of August 17 we referred to the use of chloride cells on the new launch "Aphrodite," which was recently employed by the Thames Conservancy for clearing the course during the holding of the Goring-on-Thames Regatta. We now have pleasure in giving the following details of the launch, which is illustrated in the accompanying engraving.

The general dimensions of the launch are 35ft. over all, 28ft. 6in. on the water-line, extreme beam 6ft., moulded depth 2ft. 4½in., and draught 15in. The hull is built on new and improved lines; all the framing is of best quality English oak, and the planking is of fine Honduras mahogany The top strake rubbing piece, and the whole of the inside fittings, decks, and floors are fitted up in fine-quality Moulmein teak, varnished. The metal fittings, including half-round rubbing band on covering board, are in rich

Digitized by Google

colour gunmetal, finely polished; brass screws and copper fastenings are used throughout. The arrangement of seats affords comfortable room for 12 persons, and the whole of the floor space is available. The storage cells are placed under the seats amidships, and removable lids are so arranged that any cell can be instantly inspected. The arrangement of steering gear and rudder is quite new, giving the launch very great steerage power, and enabling her to turn in but little over her own length when running at either half or full speed. The switch and steering wheel, as shown in the illustration, are fixed in the centre of the boat. The floor is covered with indiarubber mats shaped to fit, and the launch is fitted with an awning, hair-stuffed cushions, and all the necessary requirements of a first-class boat.

The launch is equipped with an electric motor of the Manchester type, wound to run at about 650 revolutions per minute, though this falls to 450 revolutions with the larger screws taking more current, but giving an increased



The Electric Launch "Aphrodite."

mileage per hour. The speed of the motor is considerably less than that generally employed on electric launches of this size, but the advantage gained is the absence of vibration and the reduced amount of attention required. A slow-speed motor is necessarily heavier than one of equal power running at a higher speed, but the weight is in this instance not of great importance, as the chloride cells give the requisite capacity with a weight considerably less than was formerly possible.

A number of tests has been made with screws of various powers running at speeds varying from 300 revolutions per minute up to 1,000, and the speed of 650 revolutions has now been decided to be the most suitable; the actual speeds per hour obtained with varying powers have been most carefully taken on a measured mile both up stream and down and the mean taken, and these are given below, together with the distances that can be travelled at these speeds with one charge:

5 miles per hour for 28 hours equalling 140 miles.
5·6 „ „ 23 „ „ 128 „
6·8 miles per hour for 6 hours equalling 41 miles.
9 „ „ 3 „ „ 27 „

Accurate times having been taken on a long day's run to ascertain what a six-hour capacity would represent, taking into account the delay at locks and the general stoppages of a pleasure party, it was found to be as follows: time running, six hours; time in locks, 1½ hours; stoppages, two hours; total, 9½ hours. It will be seen from this that the launch is capable of running at seven miles per hour for a long day's journey, and as the switch gear is fitted with full and half speed positions, and a resistance which gives four variations of each speed, power can be economised when required, so as to enable a run to be undertaken of over 100 miles.

At Goring Old Mill is fitted a 35-h.p. waterwheel, which is utilised to drive a Manchester dynamo, and a complete charging station has been fitted up. In connection with this charging station a set of accumulators has been set up which light Mr. James Shoolbred's house, some 300 yards distant, also the mill with its various workshops attached, and Mr. S. E. Saunders's new and picturesque boathouse.

It may be mentioned that Messrs. Mather and Platt, Limited, have recently been carrying out various trials with the chloride accumulators in order to prove their superiority for launch propulsion, for which purpose they are specially suited owing to their high capacity for a given weight and the rapid rates at which they can be discharged. It was for the purpose of testing these points in a practical manner that Mr. H. A. Earle, the London manager of Messrs. Mather and Platt, Limited, arranged with Mr. S. E. Saunders, of Goring-on-Thames, to build the above-mentioned launch, which, although not of a sufficient length to attain high speeds, is nevertheless one that gives ready comparison with those generally in use on the Thames. Messrs. Mather and Platt, Limited, also equipped the charging station already referred to, and which is of such a size as to be able to charge in seven hours the largest electric launch on the river.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIII. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

LESSONS.

The "Lessons of the Richmond Electric Railway," by Frank J. Sprague, reprinted elsewhere in this issue from our American contemporary the *Engineering Magazine*, reads like a chapter out of the "Arabian Nights." The lessons inculcated are nowhere tabulated, and they are left for the industrious reader to find, examine, and take to heart. We do not intend to supplement Mr. Sprague's article by tabulating the lessons. Indeed, it would be almost as Herculean a task as was the equipment of the Richmond tramways. However, there is one prominent lesson writ clearly all over the article, and more clearly all over the work. It is, given the banking account and men of ability, the pluck and energy of the scions of the Anglo-Saxons will still pull them through the most perilous and difficult paths. Fancy calmly telling us seven years after the event that the Richmond contract was taken with little or no knowledge of that class of work, except such as could be gleaned from a blue print and some experimental motors. Certainly, such a contract was unique. It was not business, yet, as the event proved, it paved the way to the vast system of electric street work that now exists in America; and though in itself a most costly contract to the contractors, no doubt it has indirectly proved a most remunerative job, in that it has led to other and paying work. We are not inclined to follow Mr. Sprague into all his statements. At that time in England the electric motor had not altogether the bad character Mr. Sprague attributes to it, but seven years after the event we may be permitted to say that the English criticism on Mr. Sprague, during the construction of the Richmond road, was that he had his business to learn. It seems that criticism was essentially correct, and that the contract was entered into without any knowledge whatsoever of the work that had to be done. The successful completion of an undertaking under these conditions speaks well for the indomitable pluck of the workers. They failed again and again. Each failure was replaced by something better, and in the end they achieved the task undertaken. Perhaps the greatest lesson to be learned is the old one so often inculcated, that a failure may prove of the utmost value to a learner. Tell us your failures as well as your successes, is often said, and here we see how, commencing in ignorance, failure with these men only meant the road to success. After all, this is really the ordinary road. No inventor, or at least hardly any, designs a perfect piece of apparatus at his first effort. He knows what he wants, and tries again and again before he succeeds. The world never knows the evolutionary processes in most cases, but here Mr. Sprague has written the inner history of one of the most important pieces of electrical work ever carried out. What lessons could be learned if, say, the inner history of electric lighting could be given. The loss at Richmond was not a Stock Exchange loss, but a loss incurred—not wilfully indeed, yet long before the work was accomplished—with eyes wide open, under the conviction that success meant a great reputation and future emoluments to the contractors, while failure meant

Digitized by Google

dropping out of the industry ruined and disgraced perhaps for ever. The difference at Richmond and some of the English work in the early eighties was just this: the one side thought of fame and future, but the other of successful Stock Exchange transactions. Our work was not intended to succeed, but to draw money from the public pocket. We should like to hear what such men as Mr. Crompton could say in this matter. He, with one or two others, has borne the burden of the fight, right through evil to good report, and made it possible for an industry to exist among us. From the time of the Richmond success the progress of electric traction in the States has been uninterrupted. As Mr. Sprague says: "The infant industry of seven years ago has grown to manhood and marks one of the most important of modern industrial advances. Six hundred railroads, 25,000 motors, and an investment of a quarter of a billion of dollars speak of its marvellous growth. The days of the horse car are limited. The cable is restricted to special localities. In suburban service already the electric car rivals the locomotive, and the latter is being gradually forced to its legitimate field of through trunk-line and freight service."

We trust that our readers will not miss one single sentence of what Mr. Sprague has written, and will, as he intends they should, take the lessons to be learned therefrom to heart. He does not wish to induce others to contract under similar conditions, but, on the contrary, to eschew such rash experiments.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ALTERNATING-CURRENT DISTRIBUTION.

SIR,—In reply to Mr. Faber's letter in your last issue, I would like to inform him that poles *are* formed on a closed magnetic circuit if the primary and secondary coils are not superposed; that when such a closed circuit is divided through these poles and left free to move, they *do* repel each other; that strong currents in both coils are just what is required; that converters do not burn up as readily as he appears to think when the secondary coil is short-circuited; that when the conditions require it, the short-circuit can be made through a resistance. With regard to the other points not being in accord with ordinary converter practice, he should remember that my controller switch plays a unique part in the circuit, being, first, a converter; secondly, a potential raiser; and, thirdly, when the primary circuit is broken, simply a pair of electromagnets, both coils being excited from the same source. I do not, therefore, expect he will find ready-made formula to suit the case.

I may further inform him that converters which I designed and made with my own hands before any of the present most excellent formulæ were thought out are still working, and can give points and a beating to many modern types, both for economy and insulation. It is not necessary that an inventor should follow accepted rules as long as he thoroughly understands natural laws and obeys them. Surely the man who built the first iron ship knew it would float, yet the vast majority were certain it would sink because it had not been publicly demonstrated. In conclusion, I can assure you, Sir, that I thoroughly appreciate the value and necessity of public trials before vast sums of money are spent on inventions, but I believe that letters such as Mr. Faber's tend to prevent inventors receiving the support necessary to such demonstrations, and therefore stop industrial development. Premature publication is more often made from necessity than choice by inventors.—Yours, etc.,

WM. LOWRIE.

September 4, 1894.

P.S.—I hope Mr. Faber's law of titles does not apply to man as well as inventions; if it does, the high places in this world must be unworthily filled.

OBITUARY.

MR. CHARLES WOOD.

We regret to record the death of Mr. Charles Wood, late chief engineer of the mechanical department at the Silvertown Works, which occurred on the 30th ult., at the early age of 55.

Charles Wood was a native of Glasgow, where he had been apprenticed to the Basin Foundry Company, for whom he worked till 1871, when he was offered the above-mentioned appointment at Silvertown, which he held up to the time of his death.

Charles Wood was highly esteemed by all with whom he came in contact in whatever capacity, and will be badly missed both as a friend and as an engineer. In his department at Silvertown all the company's cable machinery was constructed, besides various forms of electric lighting machines and apparatus, in addition to which all repairs and alterations for the various departments of the works were here carried out.

On Monday last a number of Charles Wood's friends and fellow-workers paid a last token of respect and friendship at his graveside.

CITY AND GUILDS OF LONDON INSTITUTE.

ELECTRIC LIGHTING AND POWER TRANSMISSION

PRELIMINARY EXAMINATION.—LECTURE I.

(Specially contributed.)

Gentlemen,—I suppose that each of you who has joined these classes has a particular object in view. That object may be good, bad, or indifferent, according to the standpoint from which we look. Before entering upon the real work of the session I should like to explain to you how I think these lectures and the examinations to follow can be made of the greatest use. Your aim is to get on in the world, and a noble aim it is, if properly followed. To get on does not necessarily mean the trampling upon other competitors. It may be that you simply distance them in a race which they have neglected to prepare for—in fact, in the race for existence. Now, as ever, knowledge is power; but something in your case is required besides knowledge—you must have the ability to practically utilise the knowledge you possess, so that to succeed in the profession you appear to have chosen you must have both knowledge and ability to use that knowledge. Again, the knowledge you obtain may be of two kinds—general and superficial, or real. The great value of answering questions, working problems, and attending examinations, is to ensure reality, to give concreteness, so to speak, to your knowledge. In actual work the problems are ever varying—sometimes simple, sometimes difficult, and it is the successful solution of these practical problems that gives a man position and pecuniary remuneration in his profession. Do not look upon passing this preliminary examination and the succeeding examination as your sole aim, but rather to attend these lectures, to work the questions set, to show the examiners that what you have learnt is understood and can be utilised in order to be able to employ the knowledge obtained to the grappling with the questions which arise in practical work. Success in the examination should not be *the* end; what you ought to look forward to is success in your chosen profession. Here I shall try to furnish you with some of the tools you need for that purpose, but neither I nor any other man can guarantee your using the tools to the best advantage. This

Digitized by Google

depends upon yourselves. Tools do not make a workman. His equipment may be good, his practice bad. Where both equipment and practice are good, there is not much to fear for his future. Lastly, do not be alarmed at hearing about the overcrowding of the profession. There is plenty of room at the top. It is only at the bottom that crowding takes place. Once show superiority to the ruck and you get more freedom, more scope for your abilities, more money, and more honour. The higher you rise the greater this freedom. So try to equip yourselves thoroughly for the fight, practise the use of your tools constantly, do not flag in your efforts to gain perfection, and by always doing your best you may depend upon it there will be a time in your affairs when your opportunity must come.

You are now, so far as the City and Guilds of London Institute is concerned, commencing your career. That institute is not a hard taskmaster, but should be looked upon as a friend using inducement and allurement to lead you along arduous paths, which, when traversed, prove beneficial to the traveller. It has in its wisdom divided this course into three divisions—the preliminary, the ordinary, and the honours. We have now to deal with the preliminary course, and as you each have a syllabus, it is unnecessary for me to point out the scope of the work. I shall assume that you are beginners, and know nothing of the subject.

I.—General Notions about Electromotive Force, Current, and Resistance.

The carpenter uses a 2ft. rule to measure the length of his timber, the land surveyor uses a chain to find his lengths and areas, the cornfactor uses a bushel to measure his corn, and the grocer his pound weight to weigh his goods, and so on through a variety of industries. The world of science is nothing if not exact, and thus, whenever possible, exactitude in measurement is held to be an essential. Thanks to the labours of Lord Kelvin, Latimer Clark, and others, it is perhaps more easy to make exact electrical measurements than to make exact measurements in any other branch of science or its applications. Measurement implies something to be measured. Let us try and ascertain some at least of the quantities that can be measured in a voltaic combination. You need not trouble yourselves at present about the various parts of the apparatus before you: they will each and all be explained in due course.

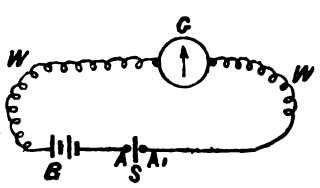

Fig. 1.

On the board I will represent the apparatus by a diagram, where B represents the battery, G a galvanometer, S a switch, W W wire connections. At the present moment the battery, B, is connected to the galvanometer, G, all round, except at A A. To connect this break I have simply to turn the switch, S, till the ends of the metal piece of the switch rest on A A_1. Before doing this, let us throw a reflection of the galvanometer on the screen. You see there is no movement of the needle.

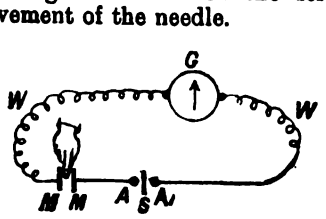

Fig. 2.

Now turn S and metallically connect A A_1. The needle moves. It comes to rest in a new position. Something has caused that needle to move, and it is our duty to investigate that something. Turn S so as to break contact between A A_1, the needle resumes its original position. Instead of the battery, B, I join the ends of the wire to these two metal plates, M M. One is a piece of zinc, the other a piece of copper. I now turn S and connect A A_1, but there is no motion of the needle. Dipping my finger into this salt water, and bringing the plates to touch the finger, as in Fig. 2, the needle again moves and comes to rest. Taking my finger away, the needle goes back to its original position. I have another battery different from the first, and connecting it up as the other, the needle swings further, but comes back again to the original position when I break the switch connection.

I am now going to indicate something similar to this outside of electricity. Here stands a glass jar filled with water connected to this glass tube by means of rubber tubing. A small piece of cork floats on the surface of the water in the tube. I lift the jar of water and immediately, as you see, the water in the tube rises, as is shown by the height of the cork. I raise the jar higher and the cork floats higher. I rest the jar once more on the table and the cork regains its original height.

In the one case I had a needle swinging further and further as I changed the battery, in the other a cork floating higher and higher as I raised the jar of water. You may have noticed that with the jar of water on the table the height of water in the jar and in the tube was the same. As soon as I raised the jar, and so increased the height of the water it contained, the water in the tube followed suit till the level of the water both in the jar and in the tube was once more the same.

Instead of the glass tube I will connect the jar to this little fountain. The jar is standing on the table and the water spurts from the nozzle. I raise the jar, and the jet gets higher and higher. I lower it to its old resting place, and the jet returns to its original height. This is not quite correct, because we have now lost some of our water from the jar. The experiment, however, will serve my present purpose, which is, that you should notice that whenever I made a *difference of level* betwixt the two ends of the connected water, that which stood lowest commenced to rise, till in the tube the water reached the same height as that in the jar: and the top of the jet would also have reached the same height as the water in the jar had there been no air in its path. You will see that directly I alter the levels of water the column of water moves in the attempt to regain levelness.

The electrical experiment has much in common with the water experiment.

The battery, whether the ordinary kind or the one made by my finger and the two metals, is a piece of apparatus we use in order to get a *difference of electrical level*. To use the electrical terminology, by its means we get a difference of *electrical potential*. There are other ways besides these I have shown you for getting a difference of electrical potential, and a large part of your time will be spent in examining the various ways.

I shall assume for the moment that whenever we have a difference of electrical potential under proper conditions we shall have a flow of something which we call electricity, and it is this electricity which causes the needle of the galvanometer to move.

Now, we can with a 2ft. rule measure the difference in the level of the water. If instead of a cork I use a piston working watertight in the tube and connected with this spring balance, as in this apparatus, when I lift the jar a pressure is made against the under part of the piston, and, as you see, by raising the jar the pressure increases, as shown by the pointer on the dial of the balance.

The pressure is proportional to the difference of level. Increasing this difference, increases the pressure; decreasing it, decreases the pressure.

The difference of electrical potential is the cause of electrical pressure, and, again, this pressure is proportional to the difference of potential, and by increasing or decreasing the latter you increase or decrease the former. Using the electrical terms, what I have called electrical pressure due to difference of electrical potential is technically called *electromotive force*. I prefer to use the term "pressure."

Just as there will be no flow of water between two pieces of water, though at different levels, and therefore under different pressures, unless there is a connecting channel, so there can be no flow of electricity unless there is a proper channel—in our case it was this copper wire. This flow of electricity we call *current*. Whatever channel water flows

Digitized by Google

through offers some opposition to the flow, and also by whatever channel or path electric current flows some opposition is made to that flow. This opposition is called *resistance*.

The phenomena of *electric pressure*, *current*, and *resistance* are the most important with which we have to deal. Each can be measured, and thus we are able to compare different pressures, currents, and resistances.

THE USE OF ACCUMULATORS WITH MOTORS.

(Concluded from page 239.)

To make this experiment still more convincing, and to show also that the results obtained are not simply due to the haphazard choice of cells, the groups thus tested were reversed in arrangement—that is, the five cells originally discharged in parallel were now discharged in series, and *vice versâ*. The following table shows the figures thus obtained from eight tests:

DISCHARGED IN PARALLEL.

No. of test.	Average current. Amperes.	Average potential difference. Volts.	Total capacity. Ampere-hours.	Watt-hours.
1	69·4	1·88	486	914
2	76·3	1·84	407	751
3	85·7	1·85	406	751
4	85·7	1·84	385	709
5	95·8	1·86	335	622
6	82·6	1·85	495	916
7	82·8	1·83	373	683
8	90·1	1·84	405	745
Mean ...	83·5	1·85	411	758

DISCHARGED IN SERIES.

No. of test.	Average current. Amperes.	Average potential difference. Volts.	Total capacity. Ampere-hours.	Watt-hours.
1	16·9	9·34	113	1,055
2	15·7	9·46	100	946
3	16·4	9·55	102	974
4	16·1	9·41	112	1,054
5	16·2	9·48	89	844
6	16·1	9·45	105	992
7	16·8	9·46	97	918
8	16·9	9·44	106	1,001
Mean ...	16·4	9·45	103	973

The difference in average efficiency or net output of energy given by these two methods is not less than 23 per cent., whilst, in addition, it should be noted that considerable discrepancies are shown by the various tests in the watt-hours obtained when discharging in parallel. All the tests were conducted with an electrolyte of identical density, so that no error might arise from serious variations therein.

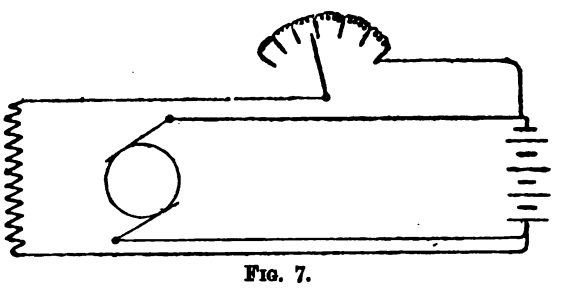

FIG. 7.

The ultimate economy of such a method as that above criticised is therefore very questionable, and the only conclusion we may safely draw is that accumulators should be arranged in series in a single group. For instance, if a battery is required to furnish a power of 10,000 watts (say 100 amperes at 100 volts) to the motor terminals, it should be composed of $\frac{100}{1·9} = 53$ cells in series; 1·9 volts being the mean potential difference of a cell having 100, 50, or 33 kilogrammes of plates according to the specific requirements.

Returning, however, to the main problem, there is still to be noticed the effect due to variations in the magnetic field, which may be of service in varying the motor speed. In connecting the field magnets in parallel with the accumulator (see Fig. 7), the excitation may be considered independent so that the working of a rheostat in the exciting circuit will produce variations in the field, and hence in the speed. An increase in the field will diminish the speed, and *vice versâ*. But in order to give a sufficiently extensive scale to the speed variations in this way, the magnets must be heavy and short with very low magnetic resistance, and not nearly saturated in ordinary working.

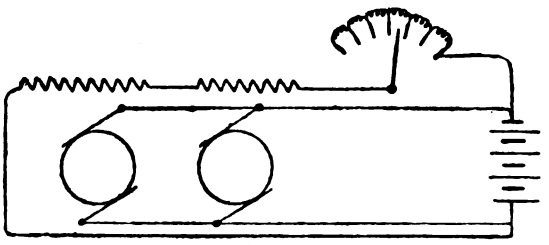

FIG. 8.

This method, when employed with a motor suitably designed, will give excellent results if the scale of varied speeds be not too extensive. When great variations are necessary, a further plan must be adopted. In this, two separate motors are employed, with the consequent advantage that there is always at least one motor to fall back upon if either fails. Two speeds at once are given by adopting this plan, according as the motors are connected in series or in parallel (see Figs. 8 and 9). Intermediate speeds are given by working a rheostat in the manner already described.

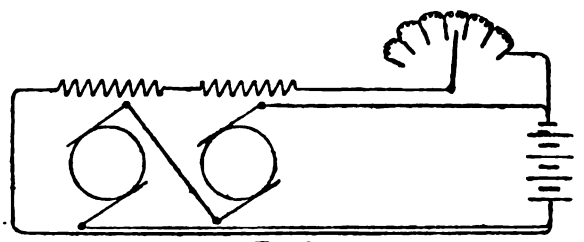

FIG. 9.

A still further refinement or means of adjusting and varying speeds is given by the use of an alternative or double winding on the motor armatures—that is, the original armature coils or sections are changed for two with twice as many turns, but with wire of half the cross-section. Two commutators are thereby necessary, as shown in Fig. 10, but their combined size need be no greater than that of the single one otherwise used. When the brushes of the same polarity of the two commutators are joined in parallel, the ordinary working is followed, but when connected in series for the same difference of potential at the termina

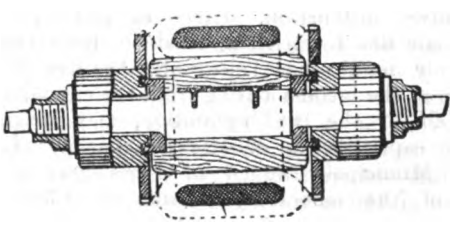

FIG. 10.

the speed is reduced one-half. This follows from the ordinary law connecting the motor speed with the armature-turns.

With two motors whose armatures are thus double wound a large number of possible variations in speed may be obtained, the rheostat in the exciting circuit being also put into use together with the different arrangements thus outlined. Moreover, this combined method seems the more satisfactory because it allows the accumulators supplying energy to be permanently coupled up in series.

Electric Lighting in France.—It is proposed to utilise the water power available at Chatillon-de-Michaille, in the Ain Department, for the purpose of driving turbines and dynamos for the electrical transmission of power.

CENTRAL ELECTRICAL LABORATORY IN PARIS.

At an assembly of the Société des Ingenieurs Civils de France, M. Max de Nansouty presented a paper dealing with the central electrical laboratory in Paris. The author pointed out that the idea of establishing such an institution for standardising or gauging instruments and to facilitate researches was of French origin, seeing that in 1881, when the guarantee committee handed over to M. Cochery the £12,000 balance of the electrical exhibition with a view to the foundation of this laboratory, no institution of this kind was in existence abroad. In consequence of delays this advance was lost, and whilst the French laboratory was only set in operation in February, 1888, a laboratory of the same kind, the Electrische Versuchsanstalt, was established in Munich in 1885-86. This laboratory, the author observed, is less important than the French one, and has been regularly worked since that time. Towards 1889 there was founded in Berlin the Physikalisch Reichsanstalt, a most important and remarkable institution. It was established by the Government, with the aid of private subscriptions. The construction and equipment of the institution necessitated considerable expenditure, and its maintenance is assured by an annual vote of £4,000. This institution, which is under the direct control of the State, undertakes all possible measurements of interest in physics and mechanics. It is under the management of Prof. von Helmholtz. A reference to the electrical laboratory of the Board of Trade was followed by a note concerning the measuring instruments in the Electrotechnical Institute at Liège, and in the Zurich Polytechnic School. Proceeding to deal with the Paris laboratory, the author stated that by a decree of February 24, 1882, the profits realised by the 1881 exhibition were directed to be devoted to the creation of an electrical laboratory in Paris under the chief management of the Minister of Telegraphs. This sum of £13,240 (331,000f.) lay idle for several years. In 1885 the Société Internationale des Electriciens proposed to the Minister of Telegraphs to undertake the establishment of the laboratory. By decree of July 12, 1886, the Minister placed at the disposal of the Société a credit of £1,200 for a provisional installation, and later in the same year the income of the 300,000f. (£12,000) remaining was provisionally devoted to the maintenance of the laboratory. As a result the Société undertook to establish a preliminary laboratory. MM. Ménier granted a site, the principal instrument and other makers presented machinery and apparatus, and the laboratory commenced work in February, 1888. The laboratory remained for five years in the Place Saint-Charles. Notwithstanding the deplorable conditions surrounding it, numerous experiments were made and many pupils received instruction. Early in 1892 the Société Internationale des Electriciens obtained from the Direction Générale des Posts et Telegraphes the free disposal of the arrears of the income arising from the capitalisation of the 300,000f. of the 1881 exhibition, and permission to devote the capital to a definite installation. In April, 1892, the Municipal Council of Paris granted for the purposes of the laboratory a site of 1,500 metres, situated in the Rue de Staël. At the same time a subscription list opened by the Société realised £4,000. The construction of the new building in that street was commenced in September, 1892, and the laboratory, completely equipped, was inaugurated in June, 1893. Since that time, owing to efforts put forth by M. Mascart, a sum of £4,000 has been granted from the funds of the Giffard legacy. This sum will defray the cost of new works in course of being carried out. Since the foundation of the laboratory more than 1,300 experiments, resulting in the issue of certificates, have been carried out. No less than 95 French or foreign pupils have received practical instructions, and *savants* and engineers have been authorised to take advantage of the resources of the laboratory for undertaking individual investigations or repeat important experiments. It is desired to make the laboratory as completely equipped as possible, and in a few months apparatus for the measurement of alternating currents will be installed.

ELECTRICITY IN HEAVY RAILROAD SERVICE.

In a recent issue (under date of May 18 last) we published an abstract of a very interesting paper brought before the Western Railroad Club by Mr. D. L. Barnes under the above title. The detailed discussion, which followed on the reading of the paper at the subsequent meetings of the club, is now before us, and since the topics involved have some considerable value for engineers in this country, more especially after the favourable working results achieved on the Liverpool Overhead Railway (results that have in all probability been responsible for serious enquiries into the advantages of working the adjacent Mersey Railway by the same system), we therefore abstract herewith the more important speeches evoked by Mr. Barnes's subject and method of dealing with it.

The discussion was opened by Mr. GIBBS, who gave it as his opinion that in average railroad service electric transmission of power will not be found more economical than the use of the steam locomotive, except where there is a substantial difference in the character and cost of fuel which is burned, could hardly be controverted. The conclusion that the same weight of bituminous coal in a stationary plant will produce the same results at the drawbar of the train is important, as showing that the alleged fuel saving by use of electricity is not in the weight used. This is a little discouraging to electricians, but they will have to devise a motor which is of higher average efficiency under different conditions of speed and power before they will accomplish anything over this result. The even pull of an electric motor, allowing an increase in hauling power, is a very important point, and will be found to be a matter of substantial gain in using the electric motor. In some late tests a locomotive with 3,000lb. less weight on the drivers and a 6in. smaller wheel, was able to haul about one car and a half more over a hill than a larger and heavier locomotive. Of course, in this comparison each locomotive had cylinder power sufficient to utilise all the adhesion due to its weight.

Mr. BAKER (general manager of the Intramural Railway at the World's Fair, and now in charge of the rolling-stock of the Metropolitan Elevated, Chicago) said that the use of alternating currents is not a matter of great importance on short lines. It may come into use later on lines of greater length The differences between it and the continuous current or in the machines used in the two currents are not so serious as to make much difference in the machines themselves, but when it comes to distribution of the current it becomes a matter of a great deal of importance. On the Intramural Railway electric motors were used under the car. The weight of the passengers assisted in getting the weight on the wheels necessary for traction. The motors themselves weigh about 20,000lb., with their attachments, whereas a locomotive to do the same work and give the same traction would weigh about 30,000lb. The result is that the trains only weigh about 80 per cent. of what they would if a locomotive, either electrical or steam, is used. That means that we have less actual work to perform in moving the train passengers over the road, and is a saving of some 20 per cent. Four motors make a very economical arrangement, because at one-fourth speed, the four motors being in series, we get the utmost economy—that is, a few seconds after leaving a station the motors are working to their full efficiency. With two motors we have to accelerate the speed through a distance of half a train length before the motors are working to their full efficiency, and with one motor it must be working at full or normal speed before this efficiency is attained. The number of passengers carried on the Intramural road May 1 to November 1 averaged a little over 33 passengers per train mile, including the light month of May. Passengers on the Manhattan road in New York average about 24 to the train mile, and on the roads in Chicago it must be considerably under what they are in New York. In the month of October we carried over 50 passengers to the train mile, so that, as far as the service goes, while we did run we did a pretty heavy service. The average speed was not fast; it was about 10 miles an hour, but it would have

Digitized by Google

been much better except for the great curvature of the line. The result of this was that after we had expended the power necessary to accelerate the train to a speed of, say, 20 or 25 miles an hour, we could have continued at that speed until necessary to put on brakes to stop at the next station for the curves. A speed curve for the train would rise to about 20 or 25 miles an hour, and then fall off to about 10 miles an hour, and continue at that speed until within braking distance of the next station. Now we could have maintained 20 miles with a very slight expenditure of power if the track had been straight. Our total cost for fuel for the month of August was 4·3 cents per train mile. For the previous months it was somewhat larger than that, but considering the disadvantages under which we worked, the short time we had to effect an organisation, and the fact that economies which we plainly saw before us could not be put in operation on account of the time required, that figure is not too low, and it can be done under the same conditions for less money than that. The arrangement of the locomotive spoken of in this paper would not make the strain on the track or structure much less than with the steam locomotive. It can be arranged, however, so that a lighter structure will do. As to the wisdom of building a lighter structure, that is another question; most of the elevated roads have been built lighter than they should be for the increased traffic. There are very few facts and figures by which you can compare the expenses of repairs of motors and locomotives, but the motor is the more simple apparatus.

Mr. BARNES: The Chicago Metropolitan Elevated will commence operations this autumn with electric motors, and the North-Western Elevated (now projected) will also be operated by electricity. It is generally conceded now that no new elevated roads will be operated except by electricity, and the Manhattan, in New York, is considering the feasibility of changing, for the reason that motor trucks can be put under the cars and the concentrated weight can be reduced. I do not see how the number of "passengers to the train mile" on the Intramural forms any indication of the traffic. That road was two or three miles long. The Manhattan is 12 miles long. In once case a man rides 12 miles for five cents and in the other two. Now on the "Alley" road here, they formerly had more passengers to the train mile even with a light traffic than they had on the Manhattan, in New York City. The weight of traffic is measured by the individual weight and speed of the individual trains when loaded. The difference between a maximum speed of 20 to 25 miles on the Intramural and the 30 to 35 miles made on the elevated roads is a ratio of 4 to 9 as the stored energy varies as the square of the speed. Also there is quite a difference in the average speeds of 10 and 15 miles an hour under the two conditions. The weight of the structure can be reduced by putting motors on cars, but the structures must be strong enough to stand the strain when the brakes are applied; the weight is not reduced as much as one would suppose, but considerably lighter structures are possible where electric motors are used.

Mr. BAKER: We ordinarily ran four cars on a train. We only had motors on the first car. Motors on every axle represent one extreme and the locomotive the other. One of our cars, weighing about 26,000lb., with about 14,000lb. passengers and about 20,000lb. motors and appliances, would make a weight of 60,000lb., which gives the traction of a 30-ton locomotive and a little more, as that only has about 20 tons on the drivers, the rest being carried by the pilot wheels. You get more traction than with the locomotive, and it is not necessary to go any further back with the motors. We have pulled eight loaded cars with one motor car, and I handled one night 12 cars with a motor car at the head and one in the middle and pulled them very easily. In letting the cars down the incline of the road at the conclusion of the fair, we had a string of over 30 cars handled by two motor cars at the head, so I do not really know exactly what they would do if they were put to it. The motors will slip the wheels, and you get all the advantage of the traction. There would be no advantage in going to the other extreme, and put a motor on each axle. You would get too complicated a state of things. But when it is a question of one large motor on a locomotive and four smaller ones on the train, I believe the question will about balance. It is a matter that would probably be very hard to get at, and would require perhaps a number of years' experience under different conditions.

Mr. GIBBS: I would like to ask Mr. Baker how he would expect to collect from outside conductors a current of 800 amperes at a speed of 40 miles an hour.

Mr. BAKER: We have run experimental trains on our own road at night at a speed of 37 miles an hour, and had no difficulty in collecting the current from the very simple arrangements we had, but it might be, if that speed had continued for a long time, the shoe with which we collect the current would have become hot. The shoe we used was a common cast-iron shoe running on a rail and kept fairly cool all the time. With the stops as frequent as on an elevated road or suburban service I do not think any trouble would be experienced at all. For long-distance service I am not prepared to meet the problem.

Mr. GIBBS: The problem that our electrical friends should solve for us as railroad men is to run a power station and supply current to a considerable and variable length of railroad line with a variable traffic, having, say, sometimes 60 trains on the road, at other times two, with a first cost of plant not unreasonably in excess of that of our present plant, and a fuel economy comparable with the figure mentioned by Mr. Barnes—1·8lb. coal per indicated horse-power per hour. This figure has been reached by a triple-expansion engine running at the most economical point of cut-off and generating a constant amount of power, but there is an immense amount of data lacking to show us that the electric railroad and power stations are at present doing the same thing for anything like that cost. The average amount of power generated by the consumption of 1lb. of coal at the central station in the principal power and electric light stations in the country are so low that we would be ashamed to acknowledge them as the average for locomotive performance. We would like to have figures for depreciation on electrical apparatus, especially on motors and their connections. From one point of view these should constitute a most durable class of machines, having no mechanically unbalanced parts, and subject only to journal and commutator friction for wear. But practice has indicated a number of structurally weak points, and frequent liability besides to impairment of insulation by reason of excess current and other causes.

Mr. STILWELL: Whether or not the actual efficiency obtained by the electric generators and motors is equal to the results obtained in the steam railway practice, I do not know. It will take some time to get sufficient experience on the electric side of that question to know its exact value. In any large steam plant that is reasonably well planned, we can operate with a consumption of 3lb. of coal per horse-power per hour.

President FORSYTH: Let me ask if this is horse-power at the drawbar of the train.

Mr. STILWELL: No, sir; at the shaft of the engine. Brake horse-power. Now the efficiency of our electrical transmission, if you assume about 20 miles distance, including the efficiency of the generator, the transformers for increasing the pressure, the transmitting circuit, reducing transformers and a motor at the other end, is at least 65 per cent. You can obtain a guarantee of the best companies in this country covering that figure, and some of them would attempt to guarantee higher figures. In some cases you can get 70 per cent. Now, if you take the efficiency to be 65 per cent., we have a horse-power for less than 5lb. of coal at our generating station. There will be some further loss in getting that to your drawbar pull undoubtedly, but I do not think that the results obtained on the Intramural road at the fair are a fair criterion for a broad comparison of the relative efficiency of these two systems. We certainly have in starting with our stationary engines a great advantage in efficiency, and we may hope in time to compete with the steam locomotive.

Mr. BARNES: I would like to ask Mr. Quereau as to the fuel required per horse-power hour on steam locomotives.

Mr. QUEREAU: A horse-power hour can be generated on a locomotive with from 25lb. to 28lb. of water with a simple locomotive. We evaporate anywhere from 5½lb. to

Digitized by Google

6lb. of water to a pound of coal in average service, not under the best conditions, which will bring it possibly to, say, 5lb. of coal. I suppose that is a little rough, but think it is perfectly safe.

TRANSMISSION OF POWER AT A CHOCOLATE FACTORY.

In a recent issue we referred to plant in use for the transmission of power at Messrs. Menier's factory at Noisiel (Seine and Marne). The following further details of the installation are given in the *Journal* of the Institution of Electrical Engineers.

There are still some objections raised against non-synchronous alternating motors. Amongst the criticisms there are perhaps two which may in some cases be justifiable. In the first case the initial torque is relatively small with a constant current. This is of little importance in cases where the torque is small at first, and increases with the speed, as with a ventilating fan, for instance; but when it is necessary to start machines offering a constant resistance and large inertia the motor will require a proportionally large starting current, and special starting devices have then to be used in order to prevent too large a strain being placed on the generators. These devices are almost as simple as those used for starting continuous-current shunt motors. The second objection raised against alternating-current motors—which in many cases need not be considered—is the impossibility of varying the speed of the machine without introducing resistances into the armature circuit. This is the main reason why such motors have not yet been employed for traction work, but apart from this case, it is usual to require a constant speed for motors. The author describes one of the first power stations in France, where motors with rotating magnetic fields are used.

MM. Menier own a large estate at Noisiel (Seine and Marne) on which water power is available. This estate has several villages, a private railway, a farm, and the well-known chocolate factory. The latter is built on the banks of the river, and is worked by three turbines of about 200 h.p. each.

The electrical installation in question is used for working agricultural appliances, and for lighting a farm at a distance of two kilometres from the factory. The installation has been working for a year, and the results have proved most satisfactory. The height of the fall varies from one to four metres, depending on the time of the year. The whole of the electrical apparatus was made by the firm of Weyher and Richemond, and designed by Mr. C. E. L. Brown.

The alternator works on the two-phase system, has eight poles, and is capable of giving 75 h.p. at 600 revolutions, and equivalent to a frequency of 40 complete alternations per second. Each half of the armature gives 150 volts at 165 amperes. The weight of the whole machine is 2,700 kilogrammes. The eight field coils are fixed radially to an outside ring of cast iron. The armature consists of a hollow drum of laminated iron discs, on the outside surface of which are fixed flat coils, and those of one phase being placed above those of the other phase. Each circuit consists of eight coils coupled in two series parallels. The ends of each circuit are connected to suitable collecting rings. Lubrication for the bearings is effected by means of rings revolving in oil-boxes.

The exciter is separately driven, and is capable of giving 90 volts and 15 amperes at 1,800 revolutions per minute, and is used for exciting a Bovet magnetic coupling as well as the alternator. This coupling requires about 50 volts and 1·5 amperes when the alternator is working at full load. A careful test was made to obtain the efficiency of this type of alternator, and the system adopted was as follows: The alternator was first run at its normal speed, and so excited as to give the normal voltage at full load; readings being also taken of the exciting current, in order to determine what power was wasted in the field. Next, the losses from friction and windage, hysteresis, and Foucault currents were measured: and from these losses, added to those in the armature and field, can be determined the efficiency of the machine. This method, although not correct in the case of a single-phase alternator, where the armature reactions produce Foucault currents in the polar masses, is, on the contrary, as correct for a two-phase alternator as it is for a continuous-current machine. The two phases of such an alternator when equally loaded produce a rotating magnetic field with respect to the armature, and having an equal velocity, but opposite in sign, to that of the armature, is consequently fixed in space like the armature field of an ordinary continuous-current machine. In an ordinary single-phase alternator there is superimposed on this fixed field a rotating field having a velocity double of that of the armature, producing extra losses, and consequently prohibiting the use of the above method for determining the efficiency. It is for the above reasons that it is possible to obtain with any given carcass a greater output with a two-phase than with a single-phase winding. For instance, the above alternator could only give an output of 40,000 watts instead of 50,000 watts if it had a single-phase winding.

For determining the internal losses, the armature was rotated by means of a small continuous-current motor the losses in which had been carefully predetermined. A first test was made with the field not excited, to ascertain what losses were due to friction and windage, and a second series of tests were then made with the field excited to give normal voltage and speed. Tests were also made at different speeds, in order to separate the losses due to hysteresis (or losses proportional to speed) from those due to Foucault and internal currents (or losses proportional to the square of the speed).

The results obtained are plotted in curves, and an abstract of the tests is given in the following table:

	At full load.	At half load.	At tenth load.
Loss in the armature	1,700	420	20
Loss in the field	1,370	1,260	1,160
Friction	540	540	540
Hysteresis	390	380	370
Foucault and internal currents	1,550	1,500	1,460
Useful power	50,000	25,000	5,000
Total power	55,560	29,090	8,550
Efficiency	90%	86%	58%

The switchboard is of polished marble, and contains a double-pole switch and fuses, an ammeter, and a hot-wire voltmeter; also, for the exciter, a voltmeter, an ammeter, and a field rheostat. There are no instruments or regulating appliances on the high-tension side. The step-up transformers are each of 15,000 watts capacity, making in all 30,000 watts. The surplus power of the alternator to be used for future extensions. These transformers raise the pressure from 150 to 2,700 volts, and are placed in a special non-oxidisable insulating oil. The windings were previously well heated in the oil, in order to drive out all moisture.

The following table gives the losses and efficiencies of these transformers:

	At full load.	At half load.	At tenth load.
Loss in the primary	150	45	6
Loss in the secondary	150	40	2
Iron losses	325	325	325
Useful power	15,000	7,500	1,500
Total power	15,625	7,910	1,833
Efficiency	96%	95%	82%

The high-tension line on leaving the transformers runs underground for 500 metres, and consists of a lead-covered steel-armoured cable, consisting of four strands, each 7mm.^{2} section, insulated with rubber. This cable was manufactured at MM. Menier's factory at Grenelle. The line is protected by double-pole lightning arresters placed in the same box as the double-pole switches and fuses. These lightning arresters consist of zinc discs separated by mica. The centre disc is connected to earth, and the outer ones to the line. The boxes containing the switches are so designed that they cannot be opened while the alternators are excited. After the underground section of 500 metres the lines runs overhead for about one kilometre, and consists of a phosphor-bronze wire 3mm. diameter.

The total resistance of each circuit is from 4·5 to 5 ohms. The maximum loss is about 2 per cent. The efficiency of the line then becomes 98 per cent. at full load, 99 per cent. at half load, and 99·8 per cent. at tenth load. The step-

Digitized by Google

down transformers are similar to the step-up transformers described above.

This installation has in use at present two biphase motors of 15 h.p. to 20 h.p., and one single-phase motor of 1½ h.p. One of the large motors drives a thrashing machine, and the other works on to a countershafting from which other agricultural appliances are driven. The small 1½-h.p. motor is used for a hay-lift. Special precautions have been taken to box in all collectors and brushes where sparking is liable to take place, in order to minimise all fire risks during the process of thrashing. The starting torque of these motors is very large, perhaps greater than at full load. The starting device consists of coils of high self-induction placed at the moment of starting across the terminals of each circuit, the motor circuits being connected to only a small number of the turns. When full speed is attained these coils are cut out.

A motor with closed armature is absolutely equivalent when at rest to a transformer with a short-circuited secondary. Placing such a machine in circuit is then equivalent to short-circuiting it at that moment. For this reason it would be necessary to place in each circuit a resistance of self-induction, in order that the current taken from the generator should not be abnormal. But, on the other hand, a strong current at low pressure is necessary in each circuit in order that the motor should start at full load. A self-induction coil or a resistance would then in themselves not be sufficient to prevent this rush of current. A transformer might be used with its fine coil connected to line, and thick coil to one of the motor circuits, but, unfortunately, by this method a high enough speed could not be obtained to allow of the transformer to be disconnected, on account of the low voltage at the transformer terminals, and, consequently, the weak field in the motor.

The combined method described above allows the motor to take a large current on starting without loading the generator, and also to obtain a high enough speed in order that the starting device may be promptly disconnected. The line current necessary for starting the motors depends on the machinery they are driving, but it varies from 40 to 50 per cent. below or above the full-load current.

Particulars and efficiencies of the system when working under different conditions are given in the following list:

1. When the Transformers are Fully Loaded and the Two Large Motors are Working Alone.

		Watts.
Useful power at the motor pulleys	13,000 + 13,000 =	26,000
Losses in the motors	2,000 + 2,000 =	4,000
Losses in the low-tension lines	120 + 280 =	400
Losses in the step-down transformers		1,200
Losses in the high-tension line		600
Losses in the step-up transformers		1,250
Losses in the alternator	700 + 1,300 + 2,450 =	4,450
Total power at the pulley of the alternator		37,900

Total efficiency of transmission = 69 per cent.

2. For a Mean Load on Three Motors.

Useful power at the motor pulleys	10,000 + 10,000 + 1,000 =	21,000
Losses in the motors		2,550
Losses in the low-tension line	65 + 155 + 20 =	240
Losses in the step-down transformers		950
Losses in the high-tension line		350
Losses in the step-up transformers		970
Alternator losses	460 + 1,260 + 2,420 =	4,140
Total power at the alternator pulley		30,200

Total efficiency of transmission = 69·5 per cent.

3. The Thrashing Machine Working Alone with an Average Load.

Power at the motor pulley		10,000
Loss in the motor		1,100
Loss in the low-tension line		65
Loss in the step-down transformers		685
Loss in high-tension line		80
Loss in step-up transformers		710
Alternator losses	110 + 1,200 + 2,370 =	3,680
Total power at the alternator pulley		16,320

Total efficiency of transmission = 61.3 per cent.

THE PACIFIC CABLE QUESTION.

The invitation of the Canadian Government to cable-manufacturing contractors to tender for the construction of a Pacific cable has now reached this country, accompanied by the specification of the conditions under which the proposed cable is to be made.

Three different forms of establishing the cable are put forward, and tenders are invited under any one of them. Under Form A it is proposed that the cable should be owned and controlled by Government, worked under Government authority, and kept in repair by the contractor for three years; under Form B the cable is to be owned, maintained, and worked by a subsidised company; under Form C the cable is to be owned, maintained, and worked by a company under a Government guarantee. Form A requires contractors to state the lowest cash price for which they will be prepared to supply and lay the cable, and the annual payment for which they will maintain it in efficient condition for three years after the whole line shall have been completed and put in operation. Form B requires the contractors to find the capital for, establish, work, and maintain the cable in efficient condition, for a subsidy to be paid to them annually for a term of years by the contributing Governments. The offers are to state the amount of subsidy to be paid and the number of years for which it will be needed. The maximum rates to be charged on messages between Great Britain and the Australasian colonies under this arrangement are to be 3s. a word for ordinary telegrams, 2s. a word for Government telegrams, and 1s. 6d. for Press telegrams. The charges on messages between Canada and the colonies to be proportionate. Form C requires the same conditions as Form B on the part of the contractor, and the offers are to state what guarantee of gross revenue will be required, the difference between gross earnings and the amount guaranteed to be made good each year to the company by the contributing Governments; the tariff of charges to be subject to official sanction. Eight routes are then given over which the cable may be carried. Of these, three have a double terminus at the southern end, one branch going to New Zealand and another to Tweedmouth, near the boundary of New South Wales and Queensland; three go direct to Queensland, and two to New Zealand only. The limit of time for the completion of the cable is three years from the date of the contract, but it is proposed that offers may be made on the basis of the shortest period within which the undertaking can be accomplished.

Time, price, quality, and distance are the four elements that contractors will have to consider, and the nature of the tenders will make it clear which of the proposed forms of contract is the most popular. Mr. Sandford Fleming, whose name is so prominently associated with the scheme, is strongly in favour of constructing the cable directly by Government as a public work. In a paper which he read before the Ottawa Conference he gave his reasons at length. They were briefly that the interests of a company and the interests of the public are not in such a matter as this identical; that while a company keeps its own profits very legitimately in sight, and endeavours to secure high dividends by keeping up the charge per message, the interest of the public is to obtain cheap telegraphy. This end can be better attained with Government money at 3 per cent. than with private money seeking to make 9 or 10 per cent., and there is, in Mr. Sandford Fleming's opinion, no reason why there should not be as great a reduction in the near future on Government telegraph messages throughout the Empire as there has been within the last 50 years upon the rates of letter postage. Such an anticipation involves, of course, the acquirement by Government of a complete system of submarine cables, and Mr. Fleming does not shrink from such a result. He quoted before the conference the example of the lately constructed cable to the Bahamas, where the first intention was to have the work done by a company with a Government subsidy of £3,000 a year for 25 years. This intention was not carried out. It was decided to make the cable a Government work, and already the charge on the colony is reduced to £1,800 a year, after full provision has been made for sinking funds and other necessary reserves. Mr. Fleming said: "Speaking for myself, I have arrived at the conclusion that the true principle to follow, looking solely at the public interests, present and prospective, is to establish the Pacific cable as a Government work. To give it to the existing company on their own terms, or perhaps on any terms, would, in my judgment, be a grave and irremediable mistake. Even to hand over the work to a new company entirely distinct from the Eastern Extension Company would scarcely mend matters. It would be impossible to prevent the two companies combining in some form to advance their common advantage to the detriment of the public interests."

His entire scheme would embrace the establishment of the Pacific cable, the purchase of all the cables of the Eastern Extension Company, and the transfer of all the telegraphs of the separate Australian colonies, together with the Pacific cable and Eastern Extension cables, to a trust or commission created by the co-operating Governments. The capital required for such a scheme he would propose to raise on the joint guarantee of the colonies and the Imperial Government. The money would be obtained at the very lowest rate of interest,

Digitized by Google

and it would thus become practicable to reduce charges on messages to the lowest possible tariff rates. By the adoption of such a scheme he considers that all conflicting interests would be conciliated. Existing companies would obtain fair terms of purchase, and the public requirement of cheap communication would henceforth become the paramount object to be kept in view.

A further letter from Mr. Sandford Fleming to Mr. Mackenzie Bowell, the Canadian Minister of Trade, dated 12 days after the rising of the conference, makes some additional statements with regard to the financial aspect of the Pacific cable undertaking which are not without interest. If the cable should take, as is generally supposed, three years to establish, 1898 will be the first year of its operation. Taking this year as the first of his estimate of revenue, Mr. Sandford Fleming calculates that the business likely to be done in that year will be 1,100,000 words, which at 2s. a word would yield a gross revenue of £110,000. This estimate, as Mr. Sandford Fleming points out, is for European business, and includes nothing for the business between Canada, the United States, and Australia, which the existence of a cable and the natural expansion of trade will undoubtedly create. The average normal increase of telegraph business between the Australasian colonies and Europe, under a tariff rate of 9s. 4d. a word, was, for the eight years between 1882 and 1890, 14 per cent. per annum. Mr. Sandford Fleming considers that, under the proposed low rates, he is justified in assuming that the increase will be greater. He takes 15 per cent. as the basis of his estimate, and works out the probable revenue of the cable for 10 years after its completion.

He also works out the charges on revenue. These are (1) interest on capital; (2) working staff and management; (3) repairs and maintenance. Of these he says that the first and second are constant and the third is variable, but experience goes to show that failure and interruptions due to defects in manufacture or causes connected with laying generally take place within the first year or two. For this reason it is proposed in the specification for constructing a Government cable that the contractor shall be responsible for repairs during the first three years, and this variable charge is for the present eliminated from the estimate prepared. Mr. Fleming takes note, therefore, only of interest on capital and cost of working. Assuming that the capital cost of the cable and its maintenance for three years will be £2,000,000, he takes interest at 3 per cent. as £60,000 a year, and cost of staff and management as £30,000. His estimate for 10 years works out then as follows: "Estimate of the business of the Pacific cable for 10 years after its completion, calculated on the basis of 1,100,000 words for the year 1898, and an average normal increase of 15 per cent. per annum thereafter:

	Gross earnings.	Interest and working expenses.	Surplus.
1898	£110,000	£90,000	£20,000
1899	126,500	90,000	36,500
1900	143,000	90,000	53,000
1901	159,500	90,000	69,500
1902	176,000	90,000	86,000
1903	192,500	90,000	102,500
1904	209,000	90,000	119,000
1905	225,000	90,000	135,500
1906	242,000	90,000	152,000
1907	258,500	90,000	168,500

"As we have eliminated all but the fixed charges on revenue for the first three years, an examination of the above table will show that the surplus up to the fourth year will have accumulated to £109,500, which sum, together with the annually increasing surplus thereafter accruing, would be sufficient to meet all charges for repairs and maintenance, and leave a balance to be carried to a cumulative reserve, for renewals at some future day."

It is worth noting in relation to Mr. Sandford Fleming's qualifications for drawing up such an estimate that at the Colonial Conference of 1887 he estimated, in a memorandum which he laid before the conference, that the business between Europe and Australasia would amount in 1893 to about 1,330,000 words. The actual business for the past year is given by Sir John Pender as 1,306,716 words, and according to Australian returns it was 1,401,293 words.

Not the least important of the papers accompanying Mr. Sandford Fleming's communication to Mr. Bowell is a statement by Mr. Alexander Siemens, which throws some light on the limits within which tenders for the construction of the cable must confine their competition.

Mr. Siemens considers, in the first place, that the proposed further survey of the cable route is unnecessary. It is in his opinion sufficiently established that the route proposed at the Wellington Conference passes nowhere through water more than 3,500 fathoms deep. The necessity for exact survey has hitherto been due to the requirements of the engineer laying the cable, who has to know at every moment the precise depth of water into which the cable passes. The brake power with which the cable is held back and by which the percentage of slack is regulated has to be adjusted according to the depth of water. If the adjustment depended entirely, as it used to do, on a knowledge of the soundings of the route, further survey would be necessary. But by a contrivance which has been used, according to Mr. Siemens, with perfect success in the laying of six Atlantic cables, "means have been devised to indicate to the brakesman continuously the percentage of slack with which the cable is paid out, and thus it is possible to lay a cable over a route of which only the general features are known." The depth offers no insuperable difficulty, as it has been found possible to construct cables for the Atlantic which will carry 7,000 fathoms of their own length before they break.

It may, therefore, in Mr. Siemens's opinion, be taken for granted that any technical obstacles which were apprehended in 1887 have now been overcome, and that the cable can be laid as soon as the financial question has been settled. In relation to the financial question, Mr. Siemens has worked out a scheme in which he assumes that the capital sum of £2,000,000 will cover the cost of the cable, of two repairing steamers of about 1,800 tons each, and of proving instruments, and leave a working capital of about £50,000. He puts the total working expenses, including repairs and maintenance, at £119,000, of which sum £90,000, or £12 per nautical mile of cable laid, are allotted to repairs. In making this very high estimate for the purpose, he states that he does so in order to be safe in the figures which he is using, and gives the ordinary calculation as £6 per nautical mile, while "one at least of the Atlantic companies is able to keep its 6,000 miles of cable in efficient working order for £4 per nautical mile." Mr. Siemens's calculation of the probable returns of the cable assumes that in regular working there will be a surplus after the first two or three years of £101,000 per annum.

The time required for the construction he estimates at three years; but for an additional outlay of £30,000 a second large cable steamer could be employed, and the time shortened to two years after commencing the manufacture.—*The Times.*

THE LEEDS TRAMWAYS.

A few months ago we published the exclusive information concerning the offers received by the Leeds Town Council for the working of the tramways, which have passed into the possession of the Council. As the Council will shortly have to decide the tramway question, a local paper summarises as follows the present position of affairs:

By the recent decision of the House of Lords in the case of the London County Council and the London Street Tramways Company (which was taken in connection with the case of the Edinburgh Corporation and the Edinburgh Street Tramways Company), which cases were on all-fours with the situation in Leeds, the Corporation are saved the difference of the arbitrator's award upon the purchase price to be paid by the Corporation to the late tramways company, this difference amounting to £61,000. The costs to the Corporation of the tramways as they now stand, therefore, amount approximately to the following figures: the initial cost of the Roundhay line was £15,232, the cost of the Harehills-road and Beckett-street extensions of the Roundhay line was £5,098, these sums being expended by the Corporation independently of the Leeds Tramways Company's undertaking. The costs at which the Corporation acquired the undertaking of the tramways company were as follows: for the line as laid they paid the sum of £58,000; for the land, depôts and offices, etc., £23,250; for the fixed plant in connection with the undertaking the sum of £823; and for the loose plant, including the engines, rolling-stock, telephones, office furniture, horses, harness, stores, etc., the sum of £35,999. To these amounts must be added the cost of the arbitration proceedings paid by the Corporation, estimated to amount to about £11,927. This makes a grand total cost to the Corporation for the entire tramway lines, including the Roundhay and Harehills-road and Beckett-street sections, together with all the property of the late tramways company taken over by the Corporation, of £150,329.

A careful estimate of the cost of relaying and putting into good order all those portions of the tram lines throughout the city which are not in perfect condition has been made by a Leeds engineer, and it amounts, in round figures, to £77,000, to which must be added the £150,329 mentioned above in order to arrive at the cost at which the tramways undertaking will stand on the books of the Corporation. From this, however, must be deducted the sum of £35,999, which, in the event of a lease of the tramways being granted, would have to be paid by the lessees to the Corporation for loose plant. Assuming that the Corporation determine to lease the tramways in accordance with the terms of the general conditions accompanying the tenders which they invited some time ago, they would have to regard the capital expenditure by them in connection with the tramways as amounting to approximately £191,330, and would have to carefully consider in what financial

Digitized by Google

way the rent to be derived from the lease of the tramways would affect such principal sum. By the conditions under which tenders were invited the Corporation are under no obligation to purchase from the lessees, at the expiration of the lease, any of the plant or material used by the lessees in connection with the tramways, and the lessees are bound by such conditions to leave any plant or material used in connection with the equipment which is placed underground, for the benefit and use of the Corporation, without receiving any consideration therefor, unless such plant or equipment can be taken up by the lessees without disturbing the surface of the streets.

In response to the advertisements of the Corporation inviting tenders for the lease of the tramways, subject to the conditions referred to above, only one tender was received, this being sent in by Mr. W. S. Graff-Baker, who instituted the Roundhay electric tramways. Mr. Graff-Baker's tender was sent in on behalf of a company with which he is associated, and the terms were as follows: for a lease of the tramway lines in Leeds for a period of 21 years, with a right to use a conduit or underground electric service in the centre of the city and an overhead wire electric service outside such centre, he offered, subject to the conditions governing the tenders, the sum of £615 per mile of single line per annum by way of rental. Including the Roundhay and Harehills-road and Beckett-street tramways, the total length of single line within the city is, in round numbers, about 28 miles, and for the use of this Mr. Graff-Baker offers £17,220 per annum. With regard to the financial effect of such rental upon the capital expended by the Corporation upon the tramways, our informant points out that this would amount, in the event of a lease being given as stated above, to £191,330; and that the interest charge per annum upon such capital outlay at 3 per cent. would amount to £5,740, which, deducted from the rent offered of £17,220, would leave the Corporation the annual sum of £11,480. Suppose that they desired to amortise the entirety of the capital cost during the period of the lease, to effect such purpose they would have to set aside a sum per annum representing just under 3½ per cent. upon the amount of capital to be amortised. Assuming that it was 3½ per cent., such sum would be equivalent to £6,696 per annum, which, deducted from the balance remaining after paying interest upon the money borrowed on capital account, would leave the annual sum of £4,784. Out of that amount the Corporation would have to pay for the maintenance of the permanent way in good order and repair, for which an allowance of £50 per mile of single line per annum would seem to be ample, having regard to the fact that the lines would be in absolutely first-class or new condition at the commencement of the lease. Such allowance would amount, for the 28 miles of single line, to £1,400 per annum, which, deducted from the £4,784 left after paying interest and amortisation, would leave an annual net sum of £3,384, to be regarded by the Corporation either as a financial profit upon their transaction in connection with the tramways undertaking or as an annual sum to be set aside for any contingencies that might arise during their ownership of the tramways.

If these figures may be relied upon, therefore, the result of a lease being granted upon the terms of Mr. Graff-Baker's offer would appear to be, that during the continuance of the lease the Corporation would have provided for them interest upon their capital expenditure in connection with the tramways undertaking, together with a fund sufficient at the expiration of the lease to amortise the entirety of such capital expenditure, in addition to providing for the maintenance and repair of the permanent way, and leaving a sum of over £3,300 per annum profit. The result of such an arrangement would, it is pointed out, be that the Leeds Corporation, at the expiration of the 21 years' lease, would find themselves owners of the entire tramway system in the city at a nominal cost only to the ratepayers, besides (according to the conditions of the tender) being under no obligation to take over the plant used by the lessees.

GLASGOW CORPORATION ELECTRIC LIGHTING.

At yesterday's (Thursday) monthly meeting of the Town Council of Glasgow, there was submitted by the Committee on Gas Supply and Electric Lighting the report, with statement of accounts, for the financial year ending May 31 last. The report stated that the gross revenue amounted to £18,591. 19s. 5d., and the gross expenditure to £9,591. 19s. 5d., to which was added the sum of £4,393. 0s. 11d. in the shape of depreciation written off capital. These two items together gave a total of £13,985. 0s. 4d., which, being deducted from the gross revenue, left a balance of £4,030. 18s. 1d., which was carried to profit and loss account. The committee had to meet the following required: (1) interest on loans, £3,438. 6s. 7d., and (2) sinking fund, £1,200—together £4,638. 6s. 7d.; and when the above-mentioned balance was deducted from that amount, there remained a deficiency on the year's operations of £607. 7s. 9d., which, in terms of the electric lighting provisional order, had been transferred to the debit of the gas account. According to the report, that deficiency was due to the public lighting rate having been fixed too low to be remunerative. Subsequently the committee went on to say that this result of the first full year's working of the three-wire low-tension system with current supplied from Waterloo-street central electric lighting station, compared favourably with the result of the previous year's (really 15 months) operations, when the deficiency was £1,773. 12s. 1d. That improvement arose from the station having been fully employed, the revenue having increased from £7,784. 5s. 4d. to £18,015. 19s. 2d., the expenditure not having increased in the same ratio. It is anticipated by the committee that this improvement will not only be maintained, but that the use of electricity will be further developed during the coming year, in which anticipation the committee are confirmed by the numerous applications for a supply of electricity which have been received since the beginning of the current year.

In order to meet the increasing demand the committee have resolved to lay down at the Waterloo-street station additional plant, consisting of two engines and dynamos and two boilers, which it is thought will be sufficient. In view of the favourable state of matters mentioned in their report, the committee, on July 25, recommended that the price of current should be reduced from 7d. to 6d. per Board of Trade unit as from June 1, which recommendation was agreed to by the Town Council at their meeting on August 2. The number of consumers at May 31 last was 378, being an increase of 270 over the number at the corresponding date of last year. The quantity of electricity sold during the year 1893-94 to private consumers, irrespective of the public lighting, was 543,178 Board of Trade units, being an increase of 107·14 per cent. over the sales made during the preceding 15 months, which is the length of time that had elapsed from the date of the electric lighting undertaking passing from the hands of Messrs Muir, Mavor, and Coulson, Limited, into those of the Corporation of the city.

When the year's electric lighting accounts in Glasgow were closed at May 31 last, the outstanding rents were estimated in the balance-sheet at £1,847. 15s. 7d., and up to August 29 there had been recovered a sum of £1,606. 2s. 7d., leaving a balance of £241. 13s. still outstanding. At the same date the gas rents still outstanding amounted to £1,510. 13s. 4d., but the amount of the outstanding rental at the close of the financial year was estimated in the balance-sheet at £61,070. 6s. 4d.

COMPANIES' REPORTS.

ELECTRIC CONSTRUCTION COMPANY, LIMITED.

Directors: Sir Daniel Cooper, Bart., G.C.M.G. (chairman); James William Barclay; Philip Edward Beachcroft; John Irving Courtenay; the Right Hon. D. R. Plunket, Q.C., M.P.; Sir Henry C. Mance, C.I.E; James Pender; Emile Garcke (managing director). Chief engineer: A. B. Blackburn, M.I.C.E Secretary: James Gray, Queen-street chambers, E.C.

Report of the directors to be presented to the shareholders at the first annual general meeting to be held on Thursday, September 13, 1894, at Cannon-street Hotel, London, E.C., at 2.30 p.m.

During the year shares and debentures of other companies have been sold at a profit of £15,764. 10s. The profit and loss account shows a gross profit of £55,362. 2s. 9d., and, after deducting all general charges, interest on debentures and borrowed capital, and cost of maintaining buildings, plant, and patents, and a sum of £3,000 for depreciation, there remains £18,467. 13s. 8d. The directors recommend that this balance be appropriated as follows: £12,500 in reducing the amount at debit of "shares and debentures of other companies' account"; £1,888. 2s. 1d. in writing off the reconstruction and preliminary expenses, and £1,819. 6s. in paying the dividend on the preference shares at the rate of 7 per cent. per annum for the year, leaving £2,260. 5s. 7d. to be carried forward to next account, making a total of £18,467. 13s. 8d. The working expenses compare favourably with those of the old company, and further economies will be carried out as opportunity offers. The liabilities of the Company have been reduced during the year by £48,236. 6s. The business has to some extent been interrupted by the reconstruction of the Company and the reorganisation at Bushbury, and under the circumstances the results for the year may be considered satisfactory. The directors have confidence in the ability and loyalty of the staff, and with the excellent factories and capable artisans of the Company improved results to the shareholders may reasonably be expected. Several important electrical contracts have been carried out during the year. The working of the Liverpool Overhead Railway was handed over to that company to their entire satisfaction on January 1 last. The electrical tramway of the South Staffordshire Tramways Company continues to be worked by this Company, and the cost of working for a period now exceeding 18 months demonstrates the great superiority and economy of electricity as compared with other modes of traction. Numerous orders for electric lighting and other applications of electricity are being executed. Messrs. James Meston and Co. were appointed to audit the present accounts, and they offer themselves for election as auditors for the ensuing year. Sir Daniel Cooper, Bart., and the Right Hon. David Plunket are the retiring directors. Sir Daniel Cooper is eligible for re-election, but Mr. Plunket, in consequence of other engagements, does not offer himself for re-election, and the directors recommend that the vacancy be not at present filled up.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Portsmouth.—The Town Council invite tenders by the 22nd inst. for the purchase of electrical plant at the Town Hall. Particulars may be obtained of the town clerk.

Edinburgh.—The Corporation, as stated in our last issue, invite tenders for the supply of arc lamp-posts. Tenders are to be directed to Mr. Wm. Skinner, W.S., town clerk, by 17th inst.

London, E.C.—The Postmaster-General invites tenders by Thursday next for the purchase of old telegraph stores. Tenders are to be sent to Mr. C. E. Stuart, controller of stores, Telegraph-street, E.C.

Barnsley.—The proprietors of the Empire Palace of Varieties, Westgate, Barnsley, require by to-morrow (Saturday) tenders for the lighting of the outside of the hall with three arc lamps, and the supply of gas-engine and dynamo. Mr. E. Haigh is the manager.

Cardiff.—Tenders are invited for wiring the Town Hall and market buildings for electric lighting purposes, including the supply and fixing of all cables, casings, switch and distributing boards, etc., but not lamps and fittings, for the Corporation of Cardiff. Plans may be seen, and copy of specification and particulars may be obtained, at the office of the borough engineer, Mr. W. Harpur, M.I.C.E., Town Hall, Cardiff, upon deposit of £1. 1s., which will be returned upon the receipt of a *bonâ fide* tender. Sealed tenders, endorsed "Town Hall, etc., Wiring," must be delivered at the office of Mr. J. L. Wheatley, town clerk, Town Hall, Cardiff, by 12th inst.

London.—The County of London and Brush Provincial Electric Lighting Company, Limited, require tenders for the supply and delivery of about 700 tons 2in. and 2½in. cast-iron spigot and socket pipes, the 2in. in 6ft. lengths, weighing not less than 42lb., and the 2½in. in 9ft. lengths, weighing not less than 84lb. per length. The interior surface must be reamed with steel-faced disc reamer to render the bore perfectly smooth, and the inside edges of both spigot and socket ends must be rounded. All to be coated inside and outside when hot with Dr. Angus Smith's composition, and to accord in every respect with the Post Office specification for similar pipes. The whole delivered by weekly instalments in barge, City-road basin, Regent's Canal, by November 1. Apply to Mr. A. J. Lawson, engineer and manager.

Ottawa.—The Government of Canada invites cable-manufacturing contractors and others to state the terms upon which they will be prepared to lay, and maintain in efficient condition, a submarine electric cable across the Pacific from Canada to the Australasian colonies. General conditions under which the offers are to be made may be ascertained on application at the Department of Trade and Commerce in Ottawa, or at the office of the High Commissioner for Canada, 17, Victoria-street, London, S.W. Proposals, based on such general conditions and in either of the three forms set forth below, to be addressed to the Minister of Trade and Commerce, and delivered at his department in Ottawa on or before November 1, 1894. Form A: The cable to be owned and controlled by Government; to be worked under Government authority, and to be kept in repair by the contractor for three years. Form B: The cable to be owned, maintained, and worked by a subsidised company. Form C: The cable to be owned, maintained, and worked by a company under a Government guarantee.

RESULTS OF TENDERS.

Reading. — The Reading Electric Supply Company have accepted the tender of Mr. E. Blackwell, Reading, for basement, etc., works at the central station, Vastern-road.

BUSINESS NOTES.

Warwick.—Warwick Castle is to be lighted by electricity.

Reigate.—The subject of introducing the electric light is being locally discussed.

Fulham, S.W.—It is suggested that the Vestry should introduce a supply of electric light.

Blackburn.—The question of lighting the streets by means of arc lamps is to be discussed.

Direct Spanish Telegraph Company.—For the month of August the receipts were £1,583, as against £1,670 for the corresponding period.

Digitized by Google

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,542.

Tunbridge Wells.—The new central electric light station is to be completed by February next.

Commercial Cable Company.—The directors announce a quarterly dividend of 1¾ per cent.

Great Northern Telegraph Company.—For the month of August the receipts were £26,800.

Yorkshire House-to-House Electricity Company.—On Monday a call of £1 on 2,634 £5 shares was made.

Montrose.—The new building to be erected by the Asylum and Infirmary Board is to be lighted by electricity.

Pontypool.—The new market is lighted electrically. The installation has been carried out by a Bristol firm.

Norwich.—A new Roman Catholic church, St. John the Baptist, has been partly completed. It is lighted electrically.

Southwark.—St. Olave's Grammar School, which has just been rebuilt at a cost of about £23,000, is to be lighted electrically.

Eastern Telegraph Company.—The receipts for the month of August were £60,279, as against £51,991 for the corresponding period.

Dundee.—The Works Committee of the Dundee Gas Commission have authorised the extension of the electric light to the police offices.

Cuba Submarine Telegraph Company.—For the month of August the receipts were £51 less than for the corresponding period of last year.

Eastern Extension Telegraph Company.—For the month of August the receipts show an increase of £2,847 as compared with the corresponding period of last year.

Leeds.—The Leeds Co-operative Society have erected new central stores in Albion-street. The building has been fitted up with the electric light by Mr. J. A. Edmundson.

Stockton.—The Board of Trade have deferred the question of revoking the Corporation's provisional order, provided that the undertaking is carried out within a certain time.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending 2nd inst. amounted to £1,152, as compared with £814 in the corresponding week of last year.

Sale of Plant.—The sale of the electrical engineering plant of Messrs. Latimer Clark, Muirhead, and Co., of Regency-street, Westminster, by Messrs. Fuller, Horsey, and Co., commenced on Tuesday.

New Swindon.—A motion on the agenda of the Local Board, in the name of Mr. Hinton, to propose the advisability of obtaining a provisional order with respect to the electric lighting of the town has been referred to a committee.

Abergavenny.—The Improvement Commissioners have decided to abandon the contemplated scheme for lighting the town by electricity, and to proceed with the extension of the gasworks to meet the requirements of the town.

Isle of Man.—A company has been registered with the object of constructing an electric tramway from Laxey to Snaefell Mountain. The capital is 25,000 shares of £1 each. The registered office of the company is 7, Athol-street, Douglas.

Wrexham.—A letter has been received by the Town Council from the Board of Trade intimating that the Board will be prepared to defer the consideration of the question of the revocation of the order of the Wrexham and District Electric Supply Company, Limited, for 12 months.

Eccles.—The Town Hall, Tramways, and Electric Lighting Committee of the Town Council have reported upon a visit they had made to Whitehaven to inspect the electric lighting works there. They were, however, not in a position yet to make any recommendations to the Council.

Redditch.—The necessity of erecting additional lamps in various parts of the district has been brought before the Local Board, but it was decided to let the matter remain in abeyance until the committee appointed to consider the subject of lighting the town by electricity have furnished their report.

City and South London Railway.—The receipts of the Company for the week ended September 2 were £794, against £747 for the corresponding week of 1893, or an increase of £47. The total receipts for the current period of the present half-year amount to £7,736, as against £7,394 in the corresponding period of 1893.

Wolverhampton.—At a meeting of the Wolverhampton Gas Company, Mr. Annan said that they had passed through a severe struggle. The electric light was being pushed forward. It would be of some disadvantage, but he did not consider it would be a great one, inasmuch as their increase went on month by month.

The Unique Switch.—We are informed that the Unique switches in all sizes and patterns are still in great request, and that, though the majority remain in England, a large number are sent abroad. A proof of this is shown by the fact that Mr. A. P. Lundberg has just received an order from Austria for 1,000, and from Africa for 500.

Lynton and Lynmouth Electric Light Company, Limited.—This Company has been registered with a capital of £8,000 to enter into an agreement with Mr. H. H. Benn, and to acquire the electric lighting business now carried on at Lynton and Lynmouth, in the county of Devon, under the style of the Lynton and Lynmouth Electric Company.

Refusal of an Application.—The St. George's, Hanover-square, Vestry have declined to give permission to the St. James's and Pall Mall Electric Lighting Company to lay an electric main in New Bond-street on the ground that the company had no powers to lay mains in the parish, in which, the surveyor stated to the Vestry, there were quite enough companies already.

Birkenhead Tramways.—The Birkenhead Town Council will meet on October 3 to consider a resolution to purchase for the sum of £2,250 the tramway rails and undertaking of the Wirral Tramway Company, Limited, situated within and outside the boundary of the borough of Birkenhead, or in the alternative so much of the tramway and undertaking only as is situated within the borough of Birkenhead.

Appointments Vacant.—As will be seen from our advertisement columns, the Town Council of Salford require a mechanical and electrical engineer. The Electric Lighting Committee of the Southport Corporation require an attendant for engines and alternators. Applications are to be sent in to Mr. J. Davies, town clerk, Southport, not later than the 15th inst. The Vestry of St. Mary, Islington, invite applications for a road foreman.

Worcester.—It was reported to the Watch Committee on Friday by the sub-committee that a number of applications for the electric light had been received. The applications acceded to included several churches, and it was stated that the dean was anxious to have it put in the cathedral. It was decided to recommend the Council to vote a sum of £1,000 as working capital to pay the cost of such extensions as the committee might decide were necessary.

Manchester.—The annual financial statement of the Manchester Corporation, issued on Friday, states that in the electric lighting department the expenditure on capital account in the past year has amounted to £86,264. 16s. 11d., and the total indebtedness of the Corporation for loans now amounts to £127,830. After setting aside £1,376. 17s. 7d. for liquidation of debt, and providing £610. 16s. 3d. for interest during construction, the year's working shows a deficit of £209. 18s. 10d.

Warminster.—With regard to the extension of the electric light in the town, the committee of the Local Board appointed to consider the question recommended that the electric light should be extended to the top of Town Hall-hill by the erection of three additional arc lamps. Mr. Brown, electrical engineer, of Walsall, had been consulted on the matter, and he has arranged to visit Warminster. It was decided to adjourn the further consideration of the matter till Mr. Brown's visit.

Cooking by Electricity.—Messrs. Crompton and Co., Limited, are showing electric heating and cooking appliances at the Food and Cooking Exhibition now being held in Manchester, and their demonstrations are exciting great interest. Several dinners have been cooked, and chops and steaks are daily supplied to visitors. The new electric grill recently introduced cooks to a nicety at a small expenditure of current. Messrs. Crompton and Co. have been awarded a diploma for gold medal.

Lincoln.—The Town Council have decided to inform the County of London and Brush Provincial Electric Lighting Company that the Corporation refuse their consent to a provisional order being granted them by the Board of Trade, as the Corporation themselves possess special facilities for lighting the city with electricity, and are quite prepared to undertake the work as soon as they are satisfied that the true interests and advantage of the citizens demand such a mode of lighting in the city.

Derby.—The electric light will probably soon illuminate Ashford Hall, the residence of Mr. R. Clifford Smith, J.P., owing to an addition being made in the shape of a billiard-room. Mr. Smith resolved upon having the electric light, and communicated with Messrs. Drake and Gorham, of London, who designed and carried out the lighting of Chatsworth. Messrs. Cox, Wilson, and Sons, of Chatsworth, have fixed a turbine which drives the dynamo. From this dynamo a cable will run to Ashford Hall, a distance of 400 yards, charging a battery of accumulators.

Chelmsford.—It has been suggested at a meeting of the Town Council that the bandstand should be lighted electrically. The Board of Trade have sanctioned the erection of overhead electric lighting wires in certain new streets, and in Barrack-square, on condition that in the event of the wires in Moulsham-street being placed underground the wires in Barrack-square should be put underground. The Board could not consent to the wires being erected overhead in King Edward's-avenue, as that appeared to be an important thoroughfare, and was in close proximity to underground wires.

Halifax.—Arrangements are to be made for lighting the new markets with the electric light. The shop known as "My Bootmakers," Bull-green, has been lighted electrically. The light, which attracted much notice in the neighbourhood, is remarkable for its steadiness and brilliancy, and proved very economical in working. The cost for running the entire installation for 4½ hours was rather less than 4d. per hour, and the actual gas consumption 630ft. The installation, which is put down by the Imperial Gas and Oil Engine Company, of West View, Booth Town, comprise 4-h.p. Imperial gas-engine, dynamo, voltmeter, 40 16-c.p. incandescent lamps, five 16-c.p. portable lamps, with all fittings complete.

Bristol.—Mr. Essery, at a meeting of the St. George's Local Board, on Wednesday raised the question of the lighting of the parish, and suggested that it was time for St. George to place itself upon a level with other districts, and adopt the latest and best system of lighting by electricity. Such a system, he said, would not cost more than gas, and with it they might have at least 100 more lamps. He proposed that a committee should be appointed to consider the matter of making provision for the

Digitized by Google

public and private lighting of the parish. Mr. Brain seconded the proposal, which was carried.

Belfast.—The Town Council have adopted the following report of the Electric Lighting Committee: "Your committee have to report that they have drawn up the following scale of rebates to be made on accounts for electric current: on quarterly accounts of £2. 10s. and up to £5, 2½ per cent.; of £5 to £7. 10s., 5 per cent.; of £7. 10s. to £10, 7½ per cent.; of £10 to £20, 10 per cent.; of £20 to £40, 12½ per cent.; of £40 to £70, 15 per cent.; of £70 and upwards, 17½ per cent. The works in connection with the central station and the laying of the mains are progressing satisfactory, and some of the engines have undergone preliminary tests."

Electric Lighting at Leigh (Lancashire).—The directors of the Leigh Co-operative Society, Limited, have decided to adopt electric lighting throughout their central premises, and are putting down a horizontal steam-engine of 18 h.p., and a large dynamo capable of supplying current to 240 lights with wires and fittings complete. By doing this they will effect a considerable reduction in their insurance policies in connection with the flour mill. Messrs. B. Verity and Sons, electrical engineers, of 29, Princes-street, Manchester, who are extremely busy in all departments at present, have been instructed to carry out the necessary work.

Birkenhead.—The confirmation of the proceedings of the Finance Committee of the Town Council was moved on Wednesday by Alderman Deakin, who said there were several rather important questions contained in the minutes. One matter was that referring to electric lighting, and he therefore proposed that the plan prepared by Mr. J. N. Shoolbred in connection with the central electric station be, with certain alterations, approved, and that the town clerk be instructed to submit the same to the Local Government Board for their approval in connection with the application for sanction to borrow £20,000 for electric lighting purposes. The resolution was seconded and carried.

Ship-Lighting.—Messrs. Ramage and Ferguson, of Leith, have launched a passenger and cargo steamer built specially for the Eastern Mediterranean local trade for foreign owners. All the cabins are lighted by electricity. A steel screw steamer, named the "Independencia," has been launched from the yard of Messrs. Napier, Shanks, and Bell, Yoker, for the Government of San Domingo. Electric light will be fitted throughout the vessel, and she will also carry a powerful search-light. A complete electric light installation has been carried out by Messrs. Paterson and Cooper in the "Oopack," which has been built by Messrs. Workman, Clark, and Co., of Belfast, for the China trade.

Dublin.—In the month of October next the Dublin Southern Tramways Company will commence operations for applying electricity to the working of their cars on the overhead system between Haddington-road, Kingstown, and Dalkey. The scheme has been mainly brought to a successful issue by the energy of Mr. J. Clifton Robinson, C.E., general manager of the Southern line of tramways, and will be of immense benefit to residents along the line. At the next half-yearly meeting of the Dublin and Lucan Steam Tramway Company the question of the reconstruction of the line will be brought forward and considered, when it is expected that a definite statement will be made on the subject by the directors.

Darlington.—Some time ago the Darlington Corporation, who own the gasworks, considered it advisable to obtain powers for the lighting of the borough by electricity. It has been deemed desirable to make an application to the Board of Trade in respect of the same, and through the borough member (Sir Theodore Fry, M.P.) a deputation of the Town Council have had an interview with the Board of Trade officials. They received assurances from Mr. Hopwood that the Board would not take any steps to revoke the powers granted to the Corporation in 1890 in regard to electric lighting, and it was also stated that the aid of the Board of Trade would be given towards including the remaining portion of the borough within the area of supply.

Dover.—Workmen from London are now engaged in putting in the conductors in the offices of the Mayor in Wood-street, and in the private house of the deputy mayor in High-street, and also in Mr. Luckhurst's jewellery shop in Snargate-street. The wiring is being carried out under the supervision of Mr. W. Sluigo, the electrical engineer who was recently engaged by the Town Council to give them advice with reference to the requirements of the Board of Trade. The work of building the electric light station is going on rapidly. The chimney shaft is nearly 90ft. high, and has about 30ft. more to be added before the top stone is put on. The top stone, or stones, will be in the shape of a large terra-cotta cap. The walls of the engine-house and boiler-house are now up.

Sheffield.—New offices and warehouses have been erected by the Midland Railway Company in Savile-street. On the Spital Hill side of the station is the engine-house, containing the latest machinery for providing the electricity and the hydraulic power. The electric light installation consists of three single-cylinder engines, made by Marshall and Sons, Gainsborough, two indicating 80 h.p., and one 30 h.p.; four 35-light arc dynamos of the Thomson-Houston pattern, and one incandescent dynamo for 300 16-c.p. lamps to light the offices, made by Mather and Platt. These not only provide the current for lighting the offices, sheds, and warehouse, but for lamps on the Grimesthorpe engine shed and Cardigan sidings. The company's electricians, under the supervision of Mr. W. Langdon, have carried out the electric installation.

Glasgow.—The Gas and Electric Committee of the Town Council have agreed that the price of gas should remain at 2s. 6d. per 1,000 cubic feet, and that the price of electric light should be continued at 6d. per Board of Trade unit, being the price to which it was reduced from 7d. some time ago. A joint meeting of the Electric Lighting Committee and the Sub-Committee of the Watching and Lighting Committee in Glasgow on the electric lighting of streets, has been held to consider the cost of lighting the streets with electricity. It was represented that, as the cost of each lamp is £30 per annum, the gas company could not continue to supply electricity at £20, as had been done since the adoption of the new illuminant. It appears that the cost is very much more than was anticipated, and £26 was suggested as the figure that should be paid in future. The sub-committee resolved to submit the proposal to the Watching and Lighting Committee.

Inverness.—Official intimation was made at a meeting of the Inverness Town Council of the intention on the part of two electric companies to apply to the Board of Trade for provisional orders to supply electricity for public and private purposes in Inverness. Mr. W. J. Smith said if the Council did not oppose the application, it was quite possible that the Board of Trade might grant one of the orders, with the result that the town might have in the future to take over the plant of the company. The Clerk stated that the Act provided that the consent of the Council must be obtained before the Board of Trade could grant the order, except under certain special circumstances. Provost Ross said it would be well that they should preserve their rights, and so be in a position, if they thought it desirable, to make a bargain with any company for the introduction of electricity. Meantime, it was resolved to refuse the consent of the Council to the applications.

"On Appro."—On Monday Mr. Commissioner Kerr heard the case of Braulik *v.* Sharpe and Kent in the City of London Court. The plaintiff, Mr. George Braulik, of 217, Upper Thames-street, claimed the sum of £2. 2s. 6d. for electrical goods supplied to the defendants, Messrs. Sharpe and Kent, of Victoria-street, Westminster. Mr. Kent, one of the defendants, said that the goods were bought on appro. The plaintiff's traveller said he admitted having taken the order on appro, but he said it was explained at the time that if the defendants wanted to return the goods in a fortnight or three weeks the plaintiff would be willing. But the defendants had kept the goods for 12 months. The defendant Kent said he bought the goods on appro, which meant that if they were not sold they were to be returned. Mr. Commissioner Kerr said he did not know the meaning of the words in the electrical trade. He adjourned the case until October 4 for trial before a jury.

Collier Audible Telephone Syndicate.—Meetings of the creditors and shareholders of this syndicate were held on Friday at Carey-street, W.C., before Mr. Wincarls, assistant receiver, who intimated that the question of a liquidator's appointment would have to be referred to the Court for decision. The syndicate was registered in April, 1891, to acquire and develop the inventions of Mr. A. T. Collier for improved telephonic receivers and transmitters, and to carry on the business of a telephone and electrical manufacturing and supply company. The promoters were the London and Colonial Finance Corporation, Limited, and the nominal capital was put at £9,000. In 1892 the Collier-Marr Telephone and Electrical Manufacturing Company, Limited, acquired the assets for £50,000, payable in cash and shares, and, with a view to carrying through the sale, the syndicate went into voluntary liquidation, but later a compulsory winding-up order was made on a creditor's petition.

Ipswich.—The Paving and Lighting Committee of the Town Council have held a meeting, at which the gas inspector said the gas company asked the co-operation of the committee in providing Welsbach lamps throughout Tavern-street and Westgate-street. Ten would be required—six for Tavern-street, and four for Westgate-street—and the gas company were willing to pay the cost of erecting six if the committee would pay for four. The cost would be 15s. each burner, and the cost of gas would be exactly the same as the present lamps, with this difference—that instead of 13 c.p. they would have about 70 c.p. Mr. Churchman: I will move that no more expenditure be incurred in experimental gas-lighting till the electric lighting question is settled. The Vice-Chairman seconded the motion. Mr. Robinson: We have no objection to the new burners being put up at the expense of the company. Mr. Churchman concurred, and added words to that effect to his resolution, which was carried.

Gas and Electricity at Hanley.—The town clerk has submitted to the Town Council a communication from the British Gaslight Company intimating that the price of gas to the private consumers in their district would be reduced from 2s. 9d. to 2s. 6d. per 1,000 cubic feet; and that there would also be a reduction in the price charged for public lighting of 5s. per lamp, making the charge £2. 15s. per lamp, from July 1 last. The Mayor remarked that their electrical energy was being rapidly taken up, and he expected that there would soon be a demand which would make it necessary for them to obtain further powers This would be pleasant news for the Council, and it would also be satisfactory for them to know that the British Gaslight Company had brought down their price for gas from 3s. 6d. per thousand (as it was when they started their agitation) to 2s. 6d. per thousand. He found by calculation that from 1888 to 1893 the sum contributed from private rentals was £152,962, and about an average of £3,000 a year from public lighting under contracts. Up to the time of the first reduction to 3s. per thousand the statutory dividends had not been paid or scarcely paid, and no amount had been placed to the

Digitized by Google

credit of the reserve fund. From that time, however, the statutory dividends had been paid, and the reserve fund had grown to £9,316. And further, in those six years the public had paid £23,860 less than they would have done under the 3s. 6d. rate, £6,050 being about the reduction in last year when the gas was reduced from 3s. to 2s. 9d. Upon the present price—reduced from 2s. 9d. to 2s. 6d.—about £5,000 per year would be saved to the ratepayers and consumers, £4,900 of which would directly affect the pockets of the consumers. The agitation of the Corporation had saved to the consumers during the six years £23,869—the whole cost of their electrical works. Those who advocated the establishment of those works knew perfectly well what the effect would be, and he was certain that those people who last year thought they were taking a bolder course than they ought to do would now be perfectly satisfied and thoroughly in harmony with any future proposals for the extension of the scheme of electric lighting. Tunstall would benefit by the reduction in the price of gas, and they ought to thank the Hanley Corporation for it. The result had thoroughly justified the action of the Town Council.

Preston.—The minutes of the Markets and Town Hall Committee of the Town Council comprised a recommendation that "to aid the sub-committee in their deliberations as to the advisability of lighting the Town Hall and Public Hall with the electric light, they be authorised to confer with Dr. John Hopkinson, of Manchester, whose terms would be at the rate of 5 per cent. on the cost of lighting, with a minimum fee of 50 guineas for travelling expenses." Alderman Birley moved a resolution to this effect, and said there had been some outside talk about employing a local firm, but he must remind them that Dr. Hopkinson was an eminent electrician, whereas the local firm in question had been established only a few years. Mr. Healey seconded the motion, and Mr. Green proposed an amendment that the matter be referred back for further consideration, as he did not see the force of engaging an electrician at a cost of 50 guineas merely to tell them where to put the light. Mr. Hale seconded the amendment. A heated discussion ensued, in which Alderman Birley emphatically denied that it was the committee's intention to give the work out of the town, and the amendment was lost by 21 votes to 7. The original motion was then agreed to.

Leeds Tramways.—The Tramways Committee of the Leeds Corporation visited Douglas on Thursday of last week, and inspected the new electric tramway to Laxey. The committee first carefully inspected the generating station at Douglas, and then, accompanied by the directors of the tramways company and the chairman of the Douglas Town Commissioners, they proceeded by special car to Laxey, and expressed admiration at the fine marine scenery opened out in the course of the seven miles' journey. At Laxey they were shown over the generating station, and made an examination of the electrical plant. The return journey was broken at Groudle, where the accumulator station was inspected. Afterwards the party were entertained to luncheon at the Groudle Hotel by the directors of the tramway company. The members of the Tramways Committee are, a local paper states, well satisfied with their visit. They obtained a good deal of information, which must be of value in coming to a decision as to the system which is best adapted to the requirements of Leeds. What the committee saw only tended to confirm the opinion formed from experience of electric traction at home. The town clerk and borough engineer are to prepare reports on the visit, and these will in due course be presented to the committee. It would, therefore, be premature to say more than this, that, so far as can be gathered, there is a very strong leaning towards electricity on the part of several members of the committee, and that the unquestionable efficiency, together with the comparative inexpensiveness of it, are outweighing the objection relative to the unsightliness of the overhead wires. The cost in Leeds must be an important consideration. The Corporation have a very extensive area to serve. If the present extent of track were doubled the city would not be too well provided for, and that would mean between 40 and 50 miles of single line. The committee have ascertained that the overhead system, including cars and full equipment, would cost between £7,000 and £7,500 per mile, and that the electric underground or the cable system would entail an expenditure of £10,000 per mile. There is thus a difference of from £2,500 to £3,000 per mile, and where so extensive a track is required that is a very important item. The question is still under consideration, but the committee are probably of opinion, after their protracted investigation, that there is little further information to be obtained in the matter, and their decision may not be much longer deferred.

Leicester.—The adoption of the Gas Committee's report with reference to the electric light undertaking has been moved by Alderman Lennard at a meeting of the Town Council. With regard to the progress of the work, he would like to say that the building was now completed. It had been erected under the direction of Mr. Colson, instead of being contracted for. The foundations for the engines and dynamos had been put in, a good part of the plant was now delivered, and the erection would be proceeded with in a few days. With regard to the price which the committee recommended, he might say that the price fixed by the order was 8d. per Board of Trade unit. The price the committee proposed to charge was 6d. per unit only. He believed the majority of towns had adopted the same price. Here and there one or two corporations had gone a little lower to begin with in order to put themselves in a better position to compete with the gas companies. There was no finality about the charge which the committee proposed to make at the outset. In course of time if they did not think it was enough they could ask for more, and, on the other hand, if they found they were making a fair profit out of it, they would be only too pleased to come and propose a reduction. A circular the gas department issued some three years ago suggested that if consumers took the current it would cost something like two or three times as much as gas. He wanted to explain that the statement was made with the idea that the maximum of 8d. would be charged, but what with the reduction in price and improvements in lamps, it would enable it to be had at much less cost, and at a greater efficiency with less amount of current than was anticipated. He should say, taking improvements and reduced price into consideration, that now electricity might be looked upon as equal in cost to gas, and he did not think any tradesman or shopkeeper would find his bills any heavier at the end of the quarter if electricity were used instead of gas. They had considerable demand for installations, having had 1,300 16-c.p. lamps applied for. The work in the town was being proceeded with rapidly, the cables would be finished in the course of a few days, and it had been done with as little inconvenience as possible to the public and tradesmen as possible. Councillor Billings seconded. In reply to Alderman Sir Thomas Wright, Alderman Lennard said his own impression was that in the course of two or three years they would be able to come to the Council and ask that the price might be reduced. The report was adopted. The Council want £17,574 for electric lighting purposes.

Hertford.—The Finance and General Committee of the Town Council have reported that they had received the following report from the Lighting Committee: "A statement of the terms on which the Corporation would be able, under the proposed scheme of electric lighting, to supply electrical energy for the lighting of private and public buildings, etc., has been circulated amongst the householders, etc., residing within the district which it is proposed to serve, with the object of obtaining some idea as to the amount of favour with which it was likely to be regarded. The information thus obtained is of service, although it was never pretended that it would be necessarily conclusive, for the experience of other towns has invariably shown that, when once such a plant is started, the demand quickly exceeds the estimate based upon previous quasi-promises. It is, however, satisfactory to the committee to find that the returns which have so far come to hand are distinctly encouraging in this respect. They represent applications for electrical energy for lighting purposes to something like treble the amount of last year's carefully revised canvass; and they indicate in addition that the proposed installation of the electric light in Hertford is regarded with favour by many who have not yet sent in returns as to the actual number of lamps which they would be prepared to instal, because they have not yet been able to ascertain their precise requirements. Negotiations with certain large consumers, including the railway companies, the post office, and the building committee of the new church are now pending, and these have not been taken into account in framing the estimates on which this report is based. Having regard, then, to the general tenor of the replies and to the returns actually received, and being assured that no further material reduction in the cost of plant or in the expenses of the generating station can be looked for in the future, and believing that no better opportunity for securing to the ratepayers of the borough a valuable and remunerative property will be gained by further delay in this matter, this committee recommends: (1) That the electric lighting scheme proposed by the engineer—extended so as to supply the Hertford General Infirmary—be carried out as speedily as possible. (2) That the engineer be instructed, with the assistance of the borough surveyor, to prepare the detailed plans for carrying out the scheme, and the requisite forms of tender for the several sections of the same. (3) That application be made to the Local Government Board for their sanction to a loan of £6,000 for the purpose of carrying out the scheme." The consideration of the subject has been postponed to allow of the ratepayers going into the question.

Canterbury.—The Town Clerk has read at a meeting of the Town Council the following letter from Messrs. Mowll and Mowll: "73, Castle-street, Canterbury, August 20, 1894. Dear Sir,—We regret that your letter of the 3rd inst. has not been answered before, but circumstances have prevented us sending you a reply. The engineer states that he is unable to give the number of gas lamps which an arc lamp would replace, as he has no data as to the number of gas lamps in use in Canterbury or plans showing their position. We beg to give you the following extract from the letter which we received from the engineer, which we trust will give you all the information you require: I beg to state, in reply to the letter, that I am unable to give the number of gas lamps which an arc lamp would replace, as I have no data as to the number of gas lamps in use in Canterbury or plan showing their position. Each arc lamp would give at least 1,000 effective candle-power, as against about 12 c.p. effective for each gas lamp. The arc lamps, however, would not replace the number of gas jets which this extra efficiency in power would represent, as each arc lamp would only replace five or six gas lamps. The cost per arc lamp for all night running would be £30, or £23 for lamps burning from dusk to midnight, these being the prices we are to charge at Dover. Assuming, therefore, that each arc lamp replaces six gas jets, the result would be that for an increase of 14 times the illumination the cost would be less than 50 per cent. increase upon the present cost of lighting by gas, the standard price of gas being £3. 13s. 6d. per street lamp for all night running. As, however, owing to the narrowness of some of your streets, additional arc lamps might be required, reducing the number of gas lamps which they would displace, you will safely assume that the illumination will be at least 20 times that from the present gas lights, and that the cost would be about double. As to the first cost of each arc

Digitized by Google

lamp, this would be provided for by the company undertaking the lighting, so that beyond the charge already mentioned the Corporation would not have to pay anything further, provided a contract were made for a term of years; but should the Corporation wish to supply their own lamps and posts, with all accessories, the cost would be between £20 and £30 per lamp, according to the system adopted and the design of the post and lamp. Any further information we shall be glad to furnish the Council with.—Yours truly, Mowll and Mowll." Alderman Cross said he thought the company had information as to the probable number of lamps that would be required, as the Electric Light Committee went round with the company's engineer and marked the places where it was thought desirable that lamps should be placed. He thought the decision then come to was that in no case could they do away with more than three lamps, and in many cases not even two. The Surveyor said the engineer the company had then was not the same as they had now. He thought they must send the company a copy of the plan showing the gas lamps. Councillor Dunn said that, seeing they had a gas contract for another 12 months, they could not go into the matter that morning, and Councillor Lukey moved that the letter be received. He did not think they need discuss it that morning, as they had nothing definite before them as to the lighting of the public streets. It was a question they might fairly leave over until the time came for the next agreement with the gas company. Councillor Harris enquired what the Electric Light Committee were doing? If the scheme were practicable he expected to have heard from them. Councillor Lukey: Will Councillor Harris move that the letter be referred to the committee? Councillor Harris: Oh, no. I shall refer it to no committee. I believe it is a dead letter. Alderman Cross moved that the letter be referred to the committee, and Councillor Dunn seconded. The motion was agreed to.

PROVISIONAL PATENTS, 1894.

AUGUST 27.

16278. **Improvements in and connected with electrical measuring instruments, organs, electrolysis, and working aluminium.** James Swinburne, Broom Hall Works, Teddington.

16280. **Utilisation of the rise and fall of the tides through the medium of floating and falling "caissons" or drums acting upon a system of multiplying wheels for production of electricity for all purposes.** Richard Manifold Craig, Hanwell-park, Hanwell, London.

16331. **Improvements in electric organs.** Percy Ross Harrison, 6, Bream's-buildings, Chancery-lane, London.

AUGUST 28.

16366. **Heat electric alarm.** Richard Brown, 7, St. Peter's-street, Preston, Lancs.

16391. **Improvements in electrical switches.** William Paul Theermann and George Christopher Elliott, 11, Great Ducie-street, Manchester.

16400. **Improvements in apparatus for generating and applying electricity to the human body.** Walter Joseph Newton, Henry James Purbrook, and Herbert de Carle Hudson, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

16408. **Improvements in printing telegraphs.** Robert Ashworth Fowden, Norfolk House, Norfolk-street, London. (Complete specification.)

16418. **Improvements in and connected with telephonic apparatus.** Jules Cerpaux and Georges de l'Escaille, 23, Southampton-buildings, Chancery-lane, London. (Complete specification.)

16423. **Improvements in or applicable to electric lamps.** Robert James Rae, 4, South-street, Finsbury, London.

16425. **Improvements in electric accumulators or storage batteries.** David Young, 11, Southampton-buildings, Chancery-lane, London. (The Hess Storage Battery Company, United States.) (Complete specification.)

AUGUST 29.

16473. **An improved system or method of arranging telephones and appliances in connection with the same, by which no currents are required either for calling for or notifying the completion of communications to the different subscribers, both the above-named signs being given automatically.** Georg Ritter, 65, Chancery-lane, London. (Complete specification.)

AUGUST 30.

16532. **An improved switch or key for electric glow lamps.** Wilhelm Emil Conze, 28, Southampton-buildings, Chancery-lane, London. (The firm of F. W. Busch, Germany.)

16540. **Improvements in apparatus for firing mines electrically.** Charles Andrew Terrey, 22, Southampton-buildings, Chancery-lane, London.

16542. **Improvements in or connected with search-light projectors.** John Brokenshire Furneaux and Henry Walker, 46, Lincoln's-inn-fields, London.

AUGUST 31.

16599. **Regulating electric currents.** Leslie Bradley Miller, 2, Gray's-inn-road, London.

16606. **Improvements in or connected with carbons for electric arc lights.** Henry Charles Barker, jun., 33, Chancery-lane, London.

SEPTEMBER 1.

16686. **Improvements in the construction of galvanic cells.** Cæsar Vogt, 38, Chancery-lane, London.

16687. **Improvements in electric alarums.** Cæsar Vogt, 38, Chancery-lane, London.

16695. **Improvements in electric lighting and extinguishing devices for gas lamps.** Siegbert Bruck, 89, Chancery-lane, London. (Complete specification.)

16696. **Improvements in or relating to electro-depositing apparatus.** Henry Le Roy Bridgman, 323, High Holborn, London.

16697. **Improvements in or relating to electro-depositing apparatus and to products obtained thereby.** Henry Le Roy Bridgman, 323, High Holborn, London.

16710. **An electric lighting apparatus to be used in connection with gas burners.** Leo Elliasson, 24, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1886.

14673. **Preparing bleaching solutions by electrolysis.** Hermite and others. (Second edition.)

1893.

7594.* **Electrolytical decomposition of chlorides, etc.** Lyte. (Amended.)

18661. **Electric telegraphs for steering, engine-room, etc., signalling.** Preston.

18805. **Electric measuring instruments.** Davies.

18951. **Electricity meters.** Edmondson.

19018. **Electrical transmission.** Davis and Fowden.

19465. **Electric distribution.** Allison. (Mailloux and another.)

1894.

7322. **Electric alarm.** Christgau.

10171. **Writing telegraphs.** Newton. (Gray.)

13208. **Field magnets for dynamos.** Allen and others.

13319. **Electric arc lamps.** Kirkegaard.

13410. **Electrical switches.** Derman and Smith.

NOTES.

Telephony at Aberdeen.—Telephonic communication is now established between Aberdeen and the villages of Skene and Echt.

Personal.—Viscount Templetown, M.I.E.E., has been elected a director of the Portrush Electric Railway Company in succession to Lord Kelvin.

Rectifiers.—Mr. Sydney F. Walker is again writing to the Welsh papers on his pet subject of rectifiers, which he now describes as "a laboratory toy."

A Fine Job.—Twenty-five pounds for supplying gas of less illuminating power than it should have been. See Monday's proceedings at Bow-street.

Exhibition at Santiago.—A mining and metallurgical exhibition is to be opened this month at Santiago. The second class is devoted to electricity.

Liquid Fuel for Central Stations.—A mixture of tar and creosote is being used for firing boilers at the central station of the Bath Electric Light Company.

A Rise.—We pointed out last week that shares of electrical concerns in this country had risen. The same thing has, we learn, taken place in the shares of Austrian electrical companies.

Gas-Motor Cars.—We learn from the *Elektrotechnischer Anzeiger* that of six Lührig gas-motor cars which were put in July on the Dresden tramway, four have from various causes been withdrawn.

Indian Telegraphs.—Including the cost of free and Government messages, the Indian telegraphs for the year 1893-94 show a profit of 2½ per cent. on the capital. This is the best return yet presented.

Manchester Technical School.—The syllabus of the Municipal Technical School and Municipal School of Art in Manchester has been issued. The institution includes an electrical engineering school.

What's Wrong?—It is a matter of notoriety that the *Times* is usually most particular about the class of advertisements which it prints, but it has this week published an advertisement of an "electric belt" maker.

Electric Lighting at Oran. — The Compagnie Nationale d'Electricité, who are represented in Algiers by Mr. Vivarez, General-Councillor, are endeavouring to obtain a concession from the Mayor of Oran for the electric lighting of the town.

Telegraphy in the East.—According to the Tientsin correspondent of the *Times*, Mr. N. R. O'Connor, C.B., the British Minister, and the Viceroy have signed the convention by which the Chinese telegraphs are to be connected with those of Burma and India.

Battersea Polytechnic.—The second session of this institution will be opened for day classes on the 17th inst. and for evening classes on the 24th inst. It may be remembered that among the laboratories possessed by the institution is one for electrical science.

Oil and Gas.—The streets of Winchcombe were lighted by gas at one time, but last year the streets were lighted by oil lamps. Now the authorities are going back to gas. Some day perhaps they will discover that there is such a thing as the electric light in existence.

Institution of Mining Engineers.—Among the visits made by the Federated Institution of Mining Engineers, who have been holding their annual meeting in Newcastle, was one to Ashington Colliery, where the electric light is employed in various departments.

Gas or Electricity.—The Hoylake Local Board have decided to advertise for a scheme and estimates for lighting the streets by electricity, but is intended to make arrangements for lighting them by gas during the ensuing winter. By the winter of 1895 there should be another story.

The Mercers' Companies Schools.—These new schools, which have been erected on the site of Barnard's-inn, in the angle between Holborn-bars and Fetter-lane, and which were opened on Tuesday, are lighted throughout by electricity, and there are no gas-mains in the building.

Telegraphy in Borneo.—The British North Borneo Company has received the following telegram in connection with the telegraph line which is being constructed across the country: "Total track cut about 90 miles. Gangs engaged in exploring for mountain route and cutting posts."

Electric Traction in France.—Among the various schemes for the introduction of electric traction in France may be mentioned that at Angoulême, where a tramway system is intended to be established. Powers have been given to Messrs. Grammont, Bellantant, and Faye for the construction of an electric tramway at Dijon.

King's College, London.—A course in architecture, building construction, and modern practice, under Prof. Banister Fletcher, F.R.I.B.A., for the session 1894-95, will be commenced at this college in the first week of October. The demonstrator is Mr. James Bartlett, and the studio instructor Mr. Banister F. Fletcher, A.R.I.B.A.

Telephonic Precision.—With reference to the statement by Mr. W. H. Preece to the effect that the telephone as an instrument of precision is scarcely sufficiently appreciated, a skit appears in *Judy* this week in which the conclusion is arrived at that the hansom cab is more to be appreciated as an instrument of precision than the telephone.

Exhibition at Sunderland.—Prospectuses and plans of the forthcoming exhibition to be opened at Sunderland in November for two months, have been issued. The exhibition will be one of marine and electrical engineering. A special building is being erected for machinery in motion. The whole of the buildings inside and out will be fitted with electric light.

Telephony in Germany.—The postal authorities have arranged for the establishment of telephonic communication between Armstadt and Erfurt and between Jena and Weimar. A long-distance telephone system is to be made between Stolp-Stolpmünde and Stettin. Berlin and Greifswald have been connected by telephone. Improvements are to be carried out in the telephone system of Munich.

Refuse Destructors for Electric Lighting.—Dr. Arthur, of London, attended a meeting of the Cardiff Health and Port Sanitary Committee and laid before them a refuse destructor scheme. He stated that taking the refuse, and removing the larger stuff, the balance "was converted into pure carbon, which could be utilised for electric lighting. . . . There would be enough carbon manufactured to light the town with electricity." The committee are going to consider the matter.

Epping Forest Railway.—One of the most interesting of the new railways authorised during last session is the Walthamstow and Epping Forest line. Starting from South-place, Finsbury, it will run underground through St. Luke's, Hoxton, Shoreditch, Kingsland, Hackney, and Upper Clapton. All this underground portion will be constructed on the Greathead shield principle. It then runs right away to High Beech *vid* Walthamstow and Chingford,

Digitized by Google

skirting the Epping Forest. It is the only line that is authorised to use either steam or electricity.

Electrically-Lighted Carriage.—According to a daily paper, a new carriage built for the German Emperor is provided with electric lamps, fed by small accumulators. One is placed on the breast of each horse, also on the point of the pole of the carriage, at the sides, and at the rear of the vehicle. Thus distributed, they will make the route at night as light as at noonday for a distance of about 50 paces from the equipage, while the vehicle itself, with its Imperial occupants, will remain in perfect darkness. At the same time the horses' eyes will not be in any way injured by the glare from the lamps.

Electric Traction at Coventry.—The hitch respecting the construction of the proposed electric tramways seems likely to be overcome, the Board of Trade, as the result of an inspection by Major-General Hutchinson, agreeing to the diversion of the line on the Warwick-road and its being placed along the side instead of the centre, provided a clear space of not less than 2ft. wide be left between the side of the car nearest the Grey Friars-green railings and those railings or any projection of them. It is proposed to proceed with the work as an unauthorised undertaking; parliamentary powers to be obtained in the next session in an omnibus Bill of the Board of Trade.

Electricity in Italy.—If the French journal *Sciences et Commerce* is to be credited, the electrical industry in Italy is in rather a bad way. At Verona, it appears, the electric supply company has lost an action brought against the gas company, and has gone into liquidation. The electric lighting company of Reggio d'Emilia has become bankrupt. At Lodi an accumulator company which undertook lighting has gone into liquidation. At Venice the Société Lyonnaise d'Eclairage au Gaz has taken action against the Municipality to withdraw the concession granted to Messrs. Walter, Mendel, and Co. for private electric lighting as infringing their monopoly, which they hold till 1927. Truly, a chapter of misfortunes.

Electrolysis.—Mr. O. Wiedeburg, in the *Zeit. Physikal. Chem.*, considers the question whether a certain maximum E.M.F. is required before electrolysis can be effected. The author believes that with any E.M.F., A, there corresponds a certain pressure, p, of the gaseous product according to the equation $A_1 - A_2 = c \log \frac{p_1}{p_2}$, and hence is of opinion that by any E.M.F., however small, electrolysis is set up. The ratio of current to E.M.F. is given by a curve consisting of two straight lines connected by a short curve, approximately a hyperbola. Where the curve is very short, an apparent break occurs, the position corresponding with the maximum of polarisation.

New Lightning Conductor.—Dr. Elliott, professor of engineering at the University College of South Wales and Monmouthshire, in providing for the protection of the chimney stack attached to the new engineering laboratory that is being built for the college by Messrs. Lattey and Co., has arranged for a coronet of galvanised iron points to surmount the chimney, resting on the ornamental swell of the coping-stone, from which two stout galvanised iron ropes, securely fastened to the body of the chimney with stout galvanised iron staples, are led to separate substantial earth-plates embedded in moist ground in the neighbourhood. The conductors have been made and erected to Prof. Elliott's designs by Messrs. Sydney F. Walker and Co., of Cardiff.

Objections to the Overhead Trolley System.—The Municipality of Dantsic have been discussing the *pros* and *cons.* of the overhead trolley system for electric cars. According to the opponents of the system, the overhead wires conveyed the idea of a hop field, the contact rollers made the noise of a swarm of bees, and the movement of the cars was like the rolling of a ship at sea. After this the *Elektrotechnischer Anzeiger* of Berlin suggests that cars should be provided with remedies for sea sickness, or that each car should have a doctor attached. Notwithstanding these remarkable assertions, the Municipality have decided to turn the horse tramways into electric tramways. The work will be given to the Allgemeine Elektricitäts-Gesellschaft, of Berlin.

Sanitary Congress, Liverpool.—A conference of Municipal and County Engineers will be held in connection with the Sanitary Congress at Liverpool on Tuesday, September 25, at 10 30 a.m. The conference will be under the presidency of Mr. A. M. Fowler, M.I.C.E., and the following papers will be read: "A Description of Some Recent Improvements in Destructors," Mr. John A. Brodie; "Disposal of Town and other Refuse by Burning," Mr. James Deas; and "The Acme Refuse Destructor," Mr. H. Royle, A.M.I.C.E. Visits will be made to the Liverpool destructor works, to the Hydraulic Power Company's station, Athol-street, to the Toxteth Park destructor works (in course of construction), and to the Liverpool Electric Supply Company's central station in Lark-lane.

Glasgow and West of Scotland Technical College.—A copy of the calendar of this Glasgow college, to which we referred in our issue of the 31st ult., has reached us for the 1894-95 session, which commences on October 1. There are both day and evening classes. In the former the departments in which regular courses have been organised are civil engineering, mechanical engineering, naval architecture, electrical engineering, architecture, chemical engineering, metallurgy, mining engineering, agriculture, mathematics and physics, and chemistry. In the evening classes the courses are in mathematics and physics, chemistry, mechanical engineering, naval architecture, electrical engineering, architecture, building construction, mining, metallurgy, agriculture, chemical industries, textile industries, art industries, and commerce. The secretary to the college is Mr. John Young, B.Sc., from whom further information may be obtained.

Another Electric Launch.—On Monday afternoon a trip was made on the Thames upon the "Velvoca," an electric launch belonging to the Battery and Motor Company, St. Margaret's Offices, 53, Victoria-street, S.W. She is 35ft. long, 6ft. 6in. beam, and 1ft. 4in. draught, and ran from Petersham Island to Teddington Lock, and thence to the new Richmond Lock and back. The batteries weigh 14cwt., and are placed in the centre of the boat, having a cover which can be used as a seat. There were used 48 cells of the company's velvo-carbon primary batteries, each capable of an output of 60 amperes for 10 hours. The velvo-carbon is a special class of negative electrode for electric batteries, consisting of ordinary carbon with a surface of carbonised cotton velvet. The batteries employing these carbons may be used with a weak solution of sulphuric acid only as a excitant. The patent incorrodible connections are made of pure silver or platinum.

Railway Carriage-Lighting in Germany.—The charging station for the electrically-lighted railway sorting tenders at the Schlesischer Railway Station, Berlin, is now in full operation. The new charging station is placed in part of the basement of the old railway station hall and consists of two rooms—one for the machinery and the other for the accumulators. There are two gas motors, furnished by Krupp, of 20 h.p. and 8 h.p. respectively, with two dynamos of corresponding size. The larger plant

Digitized by Google

is intended for ordinary working, and the smaller as a reserve. The accumulator-room is arranged so that 864 cells can be charged simultaneously. They take about 15 hours for charging. Altogether there have been fitted 445 railway sorting tenders, the work having been carried out by Messrs. W. A. Böse and Co., of Berlin. The electric light has proved to be 10s. per 24 hours per car cheaper than lighting by gas. Similar charging stations have been erected at Hamburg and Eisenach.

G. A. S.—Although the initials of the name of Mr. George Augustus Sala spell gas, he is evidently a reader of the *Electrical Engineer*. In a note in our issue of 31st ult., on the death of the Earl of Albemarle, we said that he "took a great interest in the applications of electricity, and was chairman of the late General Electric Power and Traction Company, Limited. It will be remembered that in 1890, when Lord Bury, he wrote to the *Times* a letter asking for suggestions for a verb to express progression by electric power, which called forth a large number of answers. 'To motor,' was the verb which was selected as the most suitable, but neither that nor any other of the words proposed seem to have been adopted." Now Mr. Sala writes that "when the deceased nobleman was Lord Bury, he wrote to the *Times* asking for suggestions for a verb to express progression by electric power. Many suggestions were made, and 'to motor' was the verb which was selected as the most suitable, but neither that nor any other of the words proposed seem to have passed into general use."

Electric Lighting in the City.—A correspondent, signing himself "Fiat Lux," writes to the *City Press* as follows: "It is now, I suppose, two years, more or less, since the electric light was installed in the streets of the City. Up to the present, however, the authorities have failed to extend the system to Old Jewry, which, moreover, is practically deprived of all gas lamps. At this moment, when Princes-street is up for repairs and much of the traffic is diverted through this street, locomotion becomes positively dangerous after nightfall, the Cimmerian gloom being almost unrelieved by any illuminant. Ladies of my acquaintance have objected to pass through this street at night, although the headquarters of the City police are there situated, and a vigilant officer is always on duty at the portal. It may be that the persons responsible for this state of things desire that Old Jewry should be, as far as possible, in keeping with its quaint mediæval name, and retain the aspect which it presented in the Dark Ages. But now that the surrounding Gentiles have been lightened, it is surely high time that we dwellers in Jewry should be relieved from our present benighted condition."

National Association of Colliery Managers.—The annual meeting of this society has been held this year in the Forest of Dean. Mr. F. W. T. Brain, general manager of the Trafalgar Collieries, who was elected president, in the course of his inaugural address, said that he was satisfied electricity would be largely applied for mining work in the near future. With three electric pumps working underground, the first one running since 1882, which he believed was the first known application of electricity to mining work, he could speak with confidence as to its utility. So satisfied were his company as to the advantages afforded by electricity that they were now putting down an extensive system of underground main and tail rope haulage of about 150 h.p. at a cost of several thousand pounds. Electricity applied to pumping, hauling, and coal-cutting was now in constant work in several parts of the country. With the improvements now being introduced its use would become much more general. As it was, scarcely a week passed without one seeing particulars of some new electric plant in connection with mining, and the progress shown was very notable. Electricity had passed from the experimental to the practical working stage in a short time, and against considerable odds. He regarded its future as assured and full of hope. The plant was subsequently visited, as were the works of the Electric Blasting Apparatus Company.

The Electro-Harmonic Society.—The next smoking concert of this society will take place on Friday, September 28, 1894, at the St. James's Hall Restaurant (Banquet-room), Regent-street, W., commencing at eight o'clock. The following is the programme. Artistes: The Westminster Singers, Mr. Walter Coward, Mr. Charles Ackerman, Mr. Harper Kearton, Mr. W. H. Brereton violoncello, Mr. Leo Taussig; solo pianist, Mr. Alfred E. Izard; humorous songs, Mr. James Kift; musical directors, Messrs. T. E. Gatehouse and Alfred E. Izard. Programme—Part I.: glee, "Discord, Dire Sister" (Webbe), the Westminster Singers; songs (*a*) "O, Mistress Mine," (*b*) "O, my Love's like the Red Red Rose" (traditional sixteenth century), Mr. Harper Kearton; pianoforte solo, "Ballade in G Minor" (Chopin), Mr. Alfred E. Izard; "Droop not, Young Lover" (Handel), Mr. W. H. Brereton; plantation melody, "Yo, Yah, Yo" (air by H. Kearton), the Westminster Singers, solo by Mr. C. Ackerman; violoncello solo, Mr. Leo Taussig; song, "The Sons of Mars" (Trotère), Mr. Charles Ackerman; humorous song, Mr. James Kift. Part II.: part song, "The Vacant Chair" (Root), the Westminster Singers; song, "My Pretty Jane" (Bishop), Mr. Harper Kearton; song, "Lazily, Drowsily" (I. Caryll), Mr. Walter Coward; violoncello solo, Mr. Leo Taussig; serenade, "German Polka" (Schæffer), the Westminster Singers; song, "Oh, Hear the Wild Winds Blow" (Mattei), Mr. W. H. Brereton; humorous song, Mr. James Kift.

Electric Lighting in Germany.—A scheme for the introduction of the electric light at Linden, Hanover, is projected. A commencement has been made in introducing the electric light into Biberach, where Mr. Georg Straub and Mr. Julius Mühlschlegel, millowners in a suburb, have carried out installations in their works. A petition is to be presented to the Senate for a reduction in the price for current in Hamburg. Good progress is being made with the laying of conductors in Hanover. The Limburger Elektricitätswerk intends to erect a central electric light station in Diez. After a lengthy and heated discussion the Municipality of Friederichroda have rejected the proposal to establish a central electric light station. The railway station and sidings at Kaiserslautern have been lighted electrically, and it is hoped that this fact will prove an incentive to other towns in the neighbourhood to go in for electricity. A central station is almost ready for the commencement of operations at Eibau. It is one of the largest in Germany, and the fourth in size in Saxony, where it is only exceeded by Dresden, Chemnitz, and Zwickau. It has been erected on their own account by the electrical firm of Messrs. Nitzschmann and Zschockelt, of Eibau. Two systems are employed. In Eibau and Walddorf continuous current on the three-wire system is employed, while for outlying districts to the distance of four miles rotary current will be used, and there will eventually be accumulator sub-stations. There are two large dynamos, one for continuous and one for rotary current, driven by compound engines made by the Görlitz Engineering Company. There is also a battery of accumulators comprising 136 cells. In Eibau there have been connected about 2,000 incandescent lamps, 10 arc lamps, and five electric motors. The firm have also established an independent station in Oberoderwitz in the

Digitized by Google

neighbourhood, which is used for transmission of power in the Hamann mill.

A Cool Million.—We thought that the palm for electrical fiction had been awarded to this journal on account of the wonderful adventures which befell Garnesdon some time ago (see the *Electrical Engineer* under date of May 11, 1894, and August 31, 1894), but pending the advent of Edison-and-collaborateur's novel, we feel obliged to confess that the New York *World* of August 26 last comes out easily ahead of ourselves and everybody else. This enterprising newspaper has a great genius who composes headlines, a greater one who writes column after column of elegant, high-sounding language, and the greatest of all in the person of Miss Meg Merrilies—a young and attractive lady with an ambition to rival Tesla and experience a million-volt current (number, or rather fraction, of milliamperes not stated, nor yet the periodicity, within 100,000 per second—but what do newspapers know of these things any way?). She did *it*, too, whatever the experience may be to take volts without amperes at any sort of frequency, and being a girl of scientific turn of mind, went and weighed herself on a slot machine before taking and after taking the dose. Weight—111lb.—remained the same, and the only ill effects, according to the young lady, which might have resulted were just that the "electricity would have stayed in her clothes for a time if the atmosphere had not been so humid." We wonder how many (or let us say, for the sake of credulous humanity, how few) of the ordinary public who read this elaborate effusion will take it at its proper value! As a first-rate "write-up" of Tesla's experiments, based on the plan of saying a thousand words where three single ones would do, and giving absolutely no information of any use to anybody, the *World's* startler is pre-eminently calculated to fulfil its main object—viz., to gull the public and extract some additional cents from the pockets of those who have no knowledge of electricity or its real marvels—greater than any Miss Meg Merrilies could write about.

Electric Traction in Germany.—The Hildesheim Municipality have laid down the conditions under which an electric tramway will be allowed. These have been accepted by the promoters. A project has been formulated for the construction of an electric tramway from Pössneck *viâ* Krölpa, Ranis, and Ziegenrück to Schleiz. Plans have been laid before the authorities by Mr. Müller and Mr. Krüssing. The power station will be erected in Pössneck, the water power of the River Saale being utilised, steam-engines serving as a reserve. The estimated cost of the undertaking is £75,000. Another elevated electrical railway is proposed for Berlin. The Königsberg Municipality intend themselves to construct and operate the electric tramway between Pillau railway station and Augustastrasse, to which we referred in our issue of 17th ult. The line of electric tramway between Mulhouse and Dornach, which has been carried out by Messrs. Siemens and Halske from plans by Mr. Nordmann, has now been opened for traffic. Authority has been given for the construction of an electric line between Gross-Lichterfelde, Steglitz, and Südende, which will be carried out on the Siemens and Halske system. This is the first line of the kind in the neighbourhood of Berlin through a district of a distinctly urban character. Mr. Engel has projected a line of railway at Friedland, but it has not yet been decided whether steam or electric traction will be adopted. The traffic on the electric rack railway at Barmen, which was opened in April last, is proving very satisfactory. The Municipality of Oberhausen have decided to have plans drawn up for an electric tramway between that place and Mülheim-on-the-Rühr. The Street Tramway Company of Hamburg, which has now three electric lines, has found the introduction of the system very advantageous, for in seven months their receipts have gone up by £4,042. In consequence of this, the Hamburg-Altona Horse Tramway Company are desirous of obtaining powers for an overhead trolley system on their lines. The Street Tramway Company also want to apply electric traction to further of their lines.

Terrible Indeed!—Mr. Waterhouse, R.A., in his capacity as president of the National Society for Checking the Abuses of Public Advertising, has rushed into print to protest against the use of search-light advertising. Some time ago we gave in our columns an account of what was being done by Mr. Ronald Scott in this direction when he gave a demonstration in Trafalgar-square, but Mr. Waterhouse evidently did not read the issue in question, for he has taken a long time to find out what he calls "Desecrating Nelson's Monument." He starts off with his lucubration by saying: "Perverted energy and ingenuity have been exercised in the construction of an electric lantern (*sic*), which flashes the names of articles, which the makers presumably desire to sell, on the public monuments in and around Trafalgar-square, 'the finest site in Europe.' . . . The nightly exhibition has caused great annoyance . . . depriving an indefinite number of fellow-citizens of comfort and pleasure by practising on their eyes in this way. . . . The lantern (*sic*) in Trafalgar-square is a beacon light to warn Englishmen of the results of the absence of regulation in the matter of advertising." Mr. Waterhouse, it will be seen, shifts his standpoint. First of all, he takes up the subject of desecrating Nelson's monument by advertising. He has never protested against the advertising of themselves by demagogues under the monument, which was surely worse than a harmless use of the electric light. Then he departs from that point and states that the light hurts people's eyesight, which is a statement that lacks verification—and here it may be mentioned that this Mr. Waterhouse is not the Mr. Waterhouse who invented the electricity meter which we described last June. Trafalgar-square undoubtedly has been described as the handsomest *site* in Europe, but that people go there for "comfort and pleasure" at night is a debatable point. We believe tramps go to sleep on the seats. The site is all right, but there is no beauty in the buildings. Moreover, Mr. Waterhouse, as an R.A., should know that the Nelson column should architecturally not exist at all. A column is really a portion of a building, and should support an architrave. The Nelson column supports a statue to which the griffin at Temple Bar is a thing of beauty. We may next expect a protest against the electric lights in front of the Royal Exchange which light up the statue of Wellington. Mr. Waterhouse says that there is no regulation of advertising. He is not a member of the London County Council, and evidently does not know that regulations exist with regard to sky-signs. Among the abuses of advertising which he has omitted to mention is that of writing signed letters to the daily Press with a view to making known to the public the existence of certain bodies without paying for the publicity. The people who want to study the "beauties" of Trafalgar-square go there in the daytime, when there are no electrically-flashed advertisements. They do not go there at night to view the architecture, and hence there can be no desecration of the structures.

Automatic Control of Current Intensity.—In the course of an article on this subject published in *L'Electricien* of the 1st inst., M. Leroy points out that in all cases where the electric current is used it is absolutely necessary to previously determine certain limits within which the value of the current must be constant. The minimum limit is often

Digitized by Google

of no importance, and in practice the only case where account is taken of this is in the charging of accumulators. The weakening of the current in this case is frequently the commencement of a reversal, and the use of automatic disconnecting switches has come into practice. It happens at times, owing to the irregularities in the working of the moter driving the dynamo, that the reversals referred to are frequent, and would be only of short duration if the circuit was not broken by the automatic disconnecting switch. Combination switches are employed, which open or close the circuit according as the generating dynamo develops a lower or higher E.M.F. than that of the battery. Apparatus of the same kind, M. Leroy says, could be used in an analogous case in sub-transformer stations, the employment of which has a tendency to become general in alternating-current distribution; automatic apparatus withdraw or switch in transformers according to the fluctuations of the discharge in such a manner as to cause these secondary generators to work at the highest efficiency. In the majority of cases the intensity of the current may fall to a value represented by nil without any inconvenience resulting, but the maximum limit allowable is important. The use of metallic cut-outs more or less fusible answers roughly to this condition of maximum intensity. The author goes on to say that from all points of view it is absolutely essential that the central-station engineer should be able to effectively control the maximum intensity of current that a consumer can ask for at any moment. Lead-wire cut-outs, he contends, are quite incapable of taking this part, because they are capricious and hardly safe; magnetic cut-outs, which are superior to them in regard to precision and safety, would not be much better, because they are "brutal" in their effect, and when placed in a locked box they open on the least increase of current above the maximum without being able to be closed until the arrival of the central-station representative. What is required, M. Leroy submits, is an apparatus which would cut off the current when it exceeds a certain value, but would re-establish it as soon as the resistance of the network controlled has again become such that once the circuit is closed, the intensity will not exceed the maximum value. The problem is difficult of solution, but it can be solved. There are, the author continues, two appliances the object of which is to fulfil the purpose indicated, but a third, superior to the others, he will shortly describe. In many towns in France the charge made for light is at a fixed rate per lamp installed; the customer pays the same amount, no matter what number of lamps he has alight. As a consequence of this, disputes arise, and finally the use of a meter, which is expensive, is decided upon, this often neither giving satisfaction to the consumer nor to the owner of the generating station. If, for instance, the author states, a consumer can induce the manager of the generating station to instal 20 lamps on his premises and to only charge for 10 lamps—which number, simultaneously alight, is not to be exceeded—the number of consumers supplied at the fixed contract rate per lamp would be numerous. By the use of the maximum automatic controller the guarantee of consumption is real, and the consumer can be supplied with as many lamps as he requires, whatever may be the number for which he will pay the amount agreed upon. An apparatus of this kind would, the author concludes, be taken up by all central-station owners.

A Gas Chairman on the Electric Light. — On Tuesday the half-yearly meeting of the Sheffield United Gas Company was held, at which Sir Frederick Mappin, M.P., who presided, said that the Incandescent Gaslight Company had put a weapon in the hands of gas companies which would enable them to compete in a satisfactory manner with the electric light, for they could supply as good an illuminant as the electric light at a cheaper cost. In his opinion the Welsbach burner rendered the supersession of gas by electric light extremely improbable. He thought that they had no reason to fear the opposition of the electric light experience, for they had had it with them for many years. In his opinion the electric light did not appreciably affect the increase in the consumption of gas in those towns where the public were fairly well satisfied with the gas supply. Passing the new Board school in Bow-street the other day he saw that the electric light company were fixing their apparatus to light the schools. He went inside, and found that it was not only proposed to instruct the children with this expensive light, but that the light was also being placed in the basement where the warming apparatus and other things of that description existed. It struck him that this was not the way in which the ratepayers' money should be spent. This philanthropy is amusing. The gas company presided over by Sir Frederick Mappin has made in the half-year a profit of over £54,000 at the expense of the ratepayers. As regards the wonderful effects claimed for the incandescent gas burner, Sir Frederick would do well to read the note in our last issue headed "German Electrical Trade." Mr. William Johnson, the manager and secretary of the Sheffield Electric Light and Power Company, Limited, has, however, not allowed Sir Frederick Mappin's speech to go unnoticed. He writes: "The effect of the periodical attacks on the electric light by the chairman of the Sheffield Gas Company is to focus more attention on the electric light, and his frequent protestations that the directors are not afraid of the electric light would give the utmost encouragement to electric light companies to proceed with their work, if such encouragement did not otherwise, and for substantial reasons, exist. Electric light companies have no desire to injure gas companies; indeed, the gas companies should be thankful to the electric light companies for having shown them the way to the improvement of their lamps and burners. The extended use of electric lighting should not injure the dividends of gas companies, because there is sufficient use for gas for heating, for cooking, and for power, and where the injurious effects of combustion will not be felt. Gas-engines are already largely used for running small dynamos for electric lighting, and it is an open question whether large gas-engines may not ultimately be introduced into central electric lighting stations as prime motors. . . . The real operations of the Sheffield Electric Light Company began when it received its charter, olny two years ago. At the end of last month there was an increase of electric lamps in use, and about to be put in use, of 108 per cent. since the end of August last year, and experience has shown that if it were not for the initial cost that each consumer must bear before the current can be laid on, the electric light would be taken up in Sheffield more rapidly still. In spite of this difficulty, the extension of the light is extremely satisfactory, and if any fair-minded observer will begin at the post office at the top of Commercial-street, and walk through the main thoroughfares, he cannot but be impressed with the large amount of electric lighting that is increasingly visible. Now, the whole of these consumers must have some reason for the adoption of the electric light. Either the light is no dearer than gas, or it is fulfilling some purpose that cannot be supplied by gas. The gas interests may accept which alternative they like, because it is sufficient for my present object to say that Sheffield people are not in the habit of paying for that which is naught."

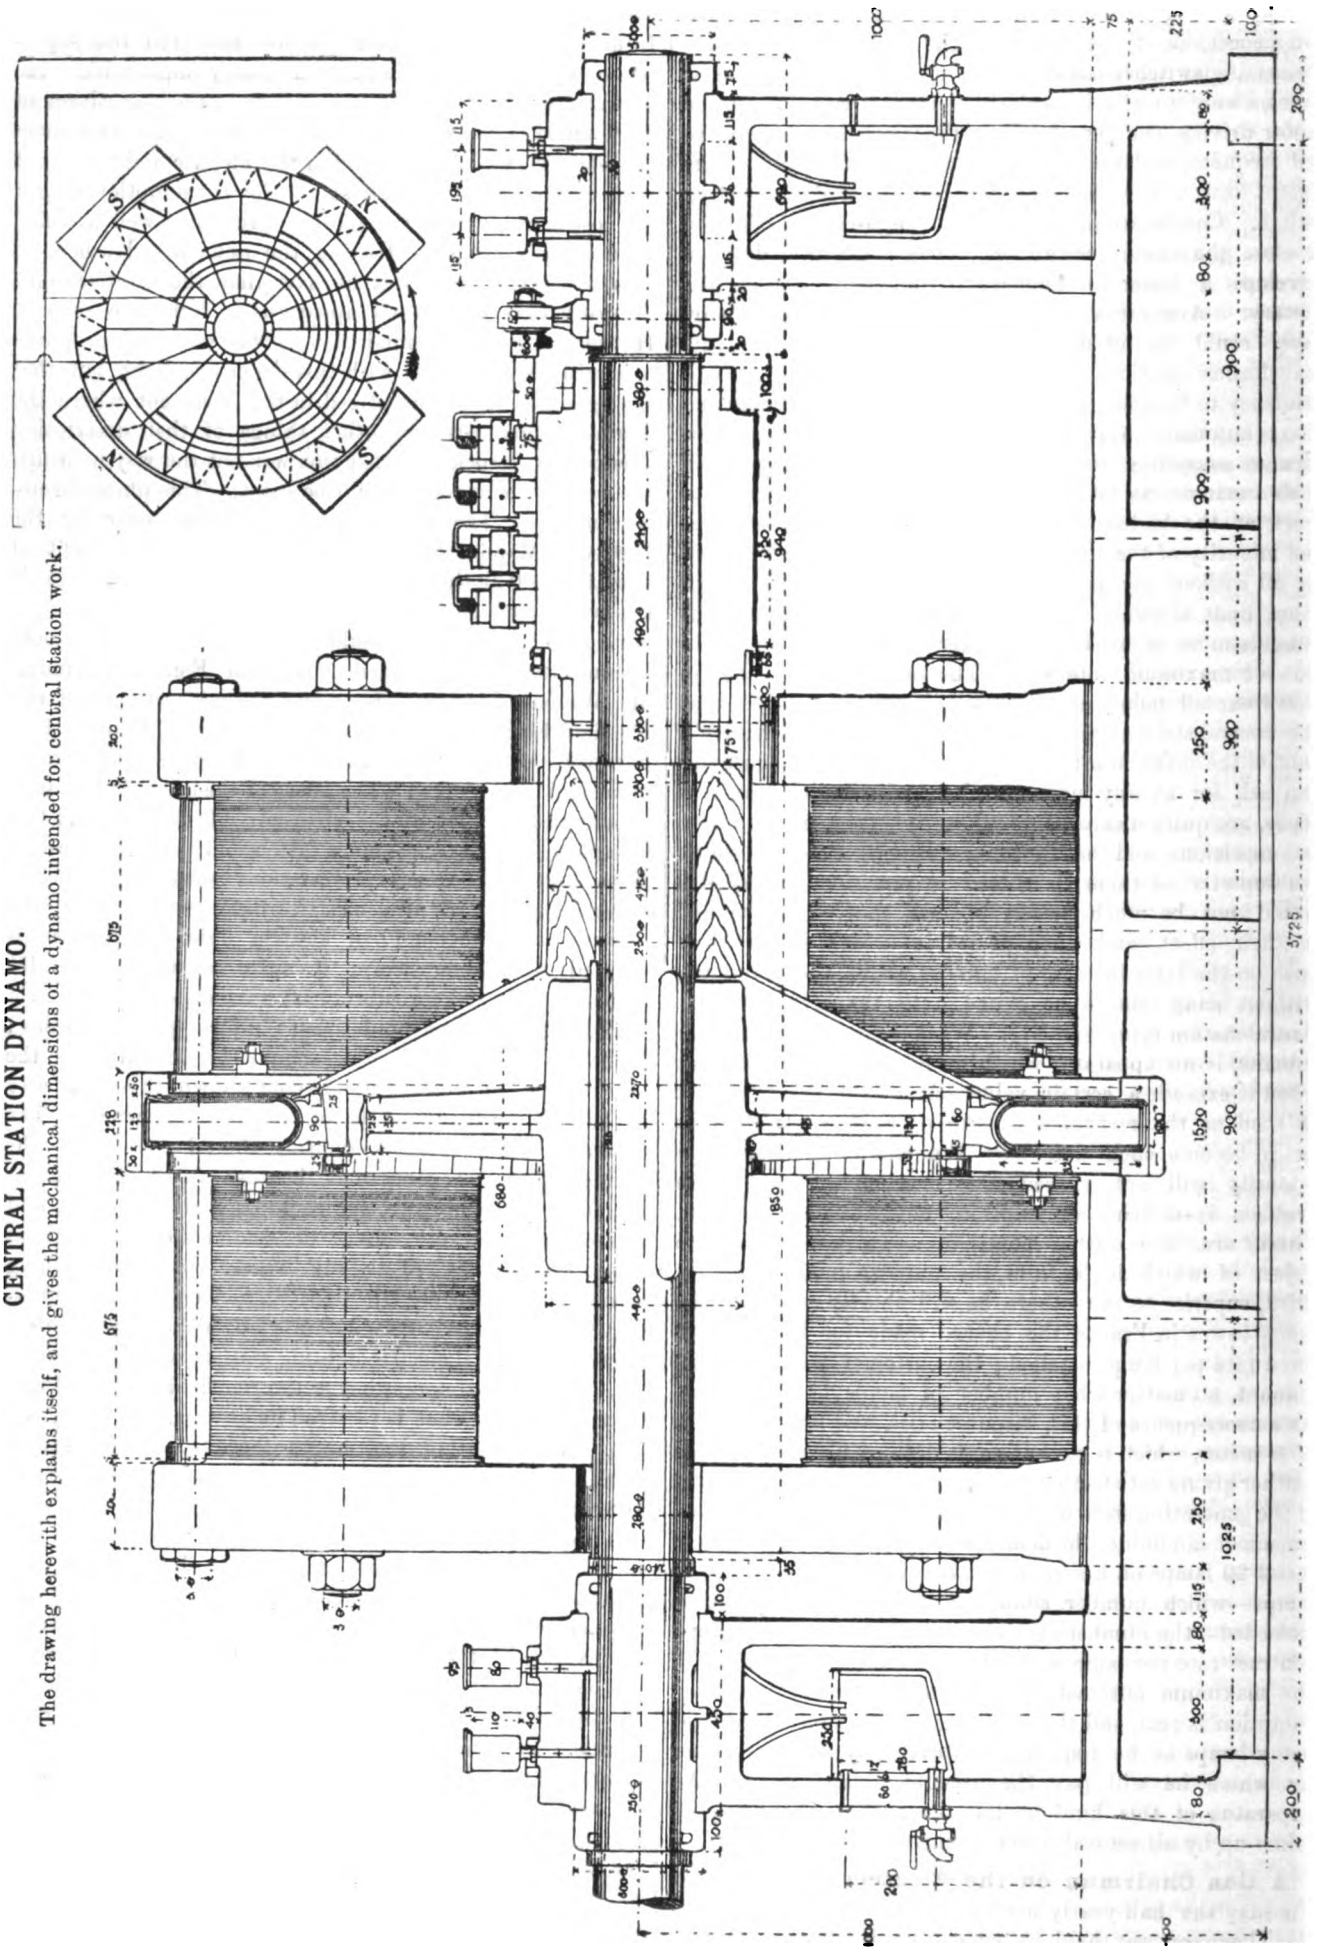
CENTRAL STATION DYNAMO.

The drawing herewith explains itself, and gives the mechanical dimensions of a dynamo intended for central station work.



Digitized by Google

MECHANICAL TRACTION FOR TRAMWAYS.

There is little need at this present time to particularise or even discuss the overwhelming importance of better traction methods for use on our tramways than the customary horses or mules: everyone concerned has for a long time realised the wasteful and inconvenient qualities of animal traction, in view of the rapid increase of our requirements in transportation matters; and the only questions now dealt with are such as relate to the most suitable system of mechanical traction to adopt for any particular district or line.

We have yet to chronicle the advent of a comprehensive treatise or book in this country which will take up the whole question of tramway working, and describe in detail the various improvements possible or practicable; but meanwhile there is continually being issued a series of valuable contributions from experts and engineers who each give the results and knowledge that they have gained in transport matters. Amongst these must be included an elaborate paper written by Mons. E. de Marchena and brought before the Société des Ingénieurs Civils of France. As a complete treatise upon mechanical traction, it is thoroughly valuable, including a detailed theoretical account of cable working, electric traction upon all the usual systems, compressed air, steam, ammonia vapour, and gas motors, etc., with a comparative discussion of such points as safety, comfort, economy, working efficiency, etc.

Within the limits and aims of our pages we cannot, of course, attempt to abstract or criticise a tithe of the contents of this paper, and we therefore give an outline only of the matters discussed generally, following this with the substance of Mons. Marchena's remarks concerning electric traction, whether using overhead wires, third rail, a conduit, or accumulators.

In his introduction, the author first examines into the question of the circumstances under which mechanical traction is advisable for tramway purposes, and the main point concerned is the character of the line—whether already worked, or yet to be built. In the former case there are obviously many expenses and a considerable outlay which do not follow on the erection of a new line, and which must be recouped from surplus profits before any benefit from the conversion is obtained. The horses need to be sold—and nearly always at a loss—the depôts altered, stables converted, stores and other buildings replaced or changed very considerably; more often than not it also becomes essential to rebuild the permanent way, since a line which serves for horse-cars will, as a rule, be quite insufficient for the heavier traffic and rolling-stock usually entailed by mechanical systems; and though the importance of economy in first cost may sometimes lead to the patching up of old lines, yet the extra expenses of repairs and renewals will very soon make up for any saving thus effected.

The great outlay required in any case for converting a line has, perhaps, too often proved sufficient to deter tramway companies from due consideration of the matter, except in instances where the advantages accruing from the use of mechanical methods have been obvious at once. Even then an extension of the lease or other powers under which the line is worked ought to be secured, in order to repay the additional charges to capital account.

When, on the other hand, a new line is to be built, great economies are effected by designing beforehand and at leisure the entire road, buildings, and equipment specially for the system to be adopted; and the only comparisons then lie between capital outlays, costs of working, etc.—comparisons which nearly always tell in favour at once of mechanical traction. The question of public favour is naturally an all-important one, since the revenue of the line depends upon it almost entirely; and, speaking generally, mechanical systems are much preferred by those who patronise tramways, because they not only give greater speeds and regularity of service, but may also be employed on heavier grades—just where lifting power is required by wayfarers.

There are also such matters to be considered as the cost of labour, price of fuel, of horses and fodder, etc. These will naturally vary in different places, and may exercise, accordingly, an important influence upon the most suitable type of traction method to adopt. As an instance, we are reminded of the lines in Brazil, Mexico, and the Argentine, where mechanical traction would be excessively dear on account of costly fuel and labour. Horses and mules, on the other hand, are in these places extremely cheap. Native unskilled labour may be hired at a very low rate, and fodder is obtainable for almost nothing. Under such circumstances, animal traction has held its own, and will probably continue to do so until the conditions change. Coming nearer home, however, it may be said practically that for any such continent as Europe—thickly populated, and therefore requiring incessant rapid intercommunication—the low cost of fuel, and the reasonable wages of skilled labour, will ensure the tolerably universal employment of mechanical traction systems.

The final considerations to take up are the conditions of traffic and the service involved. On unimportant lines with but little traffic and no severe grades, the possibilities of mechanical systems do not compare favourably with results achieved by small one-horse cars running at long intervals. When, on the other hand, there are crowded lines to operate on heavy grades with traffic varying between wide limits, the only suitable system to adopt is one of those based on mechanical motive power, which will be able to provide a quick-running and frequent service of cars at small expense. With the best care and attention the actual mortality of tramway horses must be at least from 3 to 4 per cent. per annum; and there is, besides this permanent loss, a temporary waste of power in the shape of 8 or 10 per cent. of the horses on the sick list. The frequent starts and stops required in tramway service cause rapid depreciation in horseflesh, and renewals to the live stock thereby increase the expenses of operation very heavily. Moreover, the limit to dead-weight of car is rather low with horse traction, and this implies less comfortable accommodation for passengers.

Mechanical traction systems overcome all these difficulties: the tractive effort need no longer be limited—on the contrary, heavy loads and severe grades may be encountered with much greater ease, whilst the elasticity of the service may be considered more than double that of a horse line. The average speed is increased, and more work can thus be got out of rolling-stock and staff, with greater satisfaction also to the travelling public, showing itself by increased traffic and higher receipts. It is usually found that the cost per car mile decreases when the traffic and receipts per car mile are correspondingly greater.

The next point which merits discussion—assuming that mechanical motors are decided upon—is the question as to whether single cars of self-moving type should be used or locomotives drawing a small train of several vehicles. It must, of course, be remembered that though the conditions of working tramway lines under Board of Trade regulations in this country are very different from those prevalent in Belgium, France, and Germany, where light railways are abundant and prosperous, yet it is extremely likely that more latitude will in the future be allowed to lines of such character which may be developed in this country, and hence the question is not to be lightly shelved because it assume different conditions to those now enforced.

A decision thereon must, of course, depend upon such points as the importance and volume of the traffic, the frequency of service, and the size or degree of congestion of the streets, etc., through which the line may pass. When, moreover, the average journey is of considerable length the passengers will usually wait some time for a car, knowing that its speed *en route* will make up for the delay; but when the line is a short one, and the average distance travelled but little, a frequent service becomes more desirable, single cars being run at short intervals rather than two or three at longer periods, coupled together in a train. Suburban lines running into crowded cities and towns are best worked by a frequent service of single cars, whilst "local" railways or tram lines joining adjacent towns and suburbs, etc., offer instances where satisfactory use of locomotives may be made. The cost of working is then considerably less per car mile, since one driver and conductor may serve for several vehicles, an important saving in cost of labour being thus effected.

Digitized by Google

Moreover, when repairs are necessary to a locomotive or trail-car, only the one or the other is taken off the road, whereas the self-moving car may require attention and its services are lost for the time being. Then the passengers are separated from the motive-power arrangements in the former case—a much better plan on the score of safety and personal convenience. It would, therefore, appear that much can be said for the use of "trains" of tramcars under certain special conditions, and their extended employment is to be strongly advocated when Government restrictions are removed or ameliorated.

After discussing the points thus dealt with, the author sets forth the requirements that help authorities to decide upon the most suitable system to adopt. First comes the question whether the particular method proposed will give the service required with regularity, safety, and continuity. Then follows its safety as regards the passengers as well as those who use the public highways in any manner: the inhabitants along the route followed may also raise objections to any system for this reason or that; but finally, there is the all-important question of working cost and ultimate economy.

For the most part, all mechanical systems possess nearly the same degree of favour in the eyes of the public, so that practically, for the same conditions of service, the economic results will depend on the cost of traction. This is best calculated out at per car mile, though, when all is said and done, a true comparison is extremely difficult to obtain, because the conditions in the different cases vary so enormously. In all such comparisons, moreover, the amortisation of capital outlay upon fixed plant and machinery, rolling-stock, etc., must not be overlooked, and its effect may make some considerable difference in the net financial results of the lines compared.

Starting from this standpoint, the author proceeds to classify mechanical tramway traction systems into two chief kinds, the first of which comprises all those methods wherein the operative energy is produced in a central station and distributed to motors upon the cars without storage in any way; the second includes the self-contained or "automobile" cars, carrying with them a supply of energy material sufficient for a given period of working. These we shall now examine in detail, so far as they are concerned with electrical working.

(To be continued.)

COMPARATIVE EFFICIENCY OF ELECTRIC AND CABLE TRAMWAYS.

BY FRANK B. LEA.

It seems a pity that the least animus or undue preference should be shown by the partisans of either side in advocating the choice of an electric overhead conductor or a wire-rope system for any tramway line irrespective of the special conditions that rule in each case. There is more than room for both. An ample field exists for their respective employment under varying circumstances—a field hardly touched as yet—and it is entirely too soon in the day for anyone to feel jealous. Yet there has been on the part of some an effort (let us hope an unwitting one) to praise the cable at the expense of electricity, and it may be feared that the reverse would also be seen if we had sufficient instances of electric roads to create more attention to their merits and demerits.

The writer's present aim is to show that on points of efficiency and economical working there is not very much to choose between the two systems, and that the only sensible course to adopt is to confine each method to such places and lines as shall be from their nature specially adapted to their respective use.

So far as this country is concerned, we have sadly too few cable roads to enable a definite conclusion to be drawn with respect to their efficiency; and the same want is, of course, apparent also in electric roads. Each year, however, will see an increase, and very soon we may hope to get some really trustworthy figures from which to compare different services. At present, we are obliged to take such "facts" as can be obtained, giving them bare credence until further supported by lengthened experience.

It seems a pity, in this connection, that little or nothing can be learnt with respect to one of the best cable roads—viz., that on Brixton-hill. Whether it be that the trouble of separating out the costs and the calculation of horse-power wasted is too great for consideration, or whether it be not desired for financial reasons to disclose information, cannot, of course, be said; but if cable roads are to multiply, we ought to know the exact results obtained on those already built. Electric roads have a by no means inconsiderable advantage in this respect, inasmuch as the waste of power on the line may be ascertained without much trouble and with great exactness.

Comparing the two systems, the chief losses occur, of course, between the stationary engine shaft and the car axles, and it is quite fair to balance on one side the frictional resistance of engine and toothed gear usually employed in cable work against the engine and dynamo generators of the electric road. If anything, the comparison is in favour of the former, since the efficiency of any type of gear is much less than the 95 per cent. obtainable from any well-made electric dynamo generator. The difference between this and the total waste represents the loss outside the station, being in the one case due to frictional loss in the cable, etc., and in the other to electrical loss from line resistance, underworked motors, motor gears, etc. In a recent number of the *Railroad Gazette* some figures were published to show the losses incurred on certain cable roads outside the station, and these are presumably average instances, seeing that the results are not regarded as extraordinary. If they are wrong or excessive it is the duty of cable tramway engineers to say so, and give reasons or substantiate what they say: and we may hope that this will be done, if possible.

The data given are set forth in the accompanying Table A. They were taken at four different power stations, representing eight different cables, and the observations were made for a period of 20 hours from starting time in the morning until stopping at night. The horse-power necessary to drive each cable was found by subtracting the frictional horse-power of the engine and machinery from the horse-power developed in driving the cable in the morning before the cars were taken out, and therefore with no load on.

TABLE A.—Frictional Resistance on Cable Roads.

Station.	Engines in station.	Horse-power of each.	Cable feet.	Speed miles an hour.	Total curvature.	Horse-power.			
						To drive cable.	Engine and machinery.	Total.	Maximum observed.
No. 1.	2	1,200	26,000 18,500	10 5 10·7	None. None.	98 87	53·32	238·32	1,122·00

Digitized by Google

Taking these results as they stand, we may calculate the percentage of horse-power lost in the cable to the *maximum* horse-power developed; and here, again, the cable is treated as fairly as possible, for obviously the percentage of cable loss to *average* horse-power, or to the *useful* horse-power, would be still higher. For arriving at a standard or maximum of efficiency, we may, however, take the maximum horse-power in both cases as being the average amount. The four roads above would show on this basis the following results:

No. 1. Cable loss, 16·48 per cent. of maximum horse-power.
2. „ 24·21 „ „ „
3. „ 31·14 „ „ „
4. „ 20·82 „ „ „

Of course, these figures would be still higher if we took the horse-power at the cable drum axle, instead of the indicated horse-power of the engines (from which the maximum horse-power observed is calculated). The cable loss is practically constant whatever the load, so that the latter may be disregarded.

It is much to be wished that similar figures could be given for electric roads. The only way to effect a comparison is to use the results obtained in the limited amount of working so far experienced. It may, however, be said with ample safety that an average electric road will give a line efficiency of at least 95 per cent. Higher values than this have been obtained on many lines, and with sufficient constancy to be considered normal. The commercial efficiency of motors and gearing combined is at least 75 per cent., and 82 per cent. is a fairer average. Taking the latter figure, we get a combined efficiency of, say, 78 per cent., or a loss in the line and motors, etc., of 22 per cent. of the horse-power at the dynamo terminals. This percentage would be considerably less when taken with respect to the maximum indicated horse-power of the engine cylinders, as was done above in the case of the cable roads; but even without such an allowance, electric working offers great economy.

As compared with the cable losses above mentioned, this result shows quite as good an efficiency, if, indeed, not much better; but the figures regarded altogether would tend to confirm one very strongly in feeling that both systems stand at present pretty much on a level. They each have qualities which fit them respectively for different work, and for a municipality or tramway company to say "We will equip all our lines with cable"—or electric overhead wires, as the case may be—savours too much of blind prejudice, unless every care has been taken to discuss the adaptability of each method for the various districts involved.

CITY AND GUILDS OF LONDON INSTITUTE.

LECTURE II.—THE PRINCIPLES OF ELECTRIC CIRCUITS, SIMPLE AND BRANCHING.

(Specially contributed.)

It is necessary to know something more about the channel or path of the electric current. Here, again, we may learn something from experiments with water. I have before you a glass cistern with two compartments, A and B (Fig. 1). These compartments are connected by means of the pipe, C, which can be closed or opened by

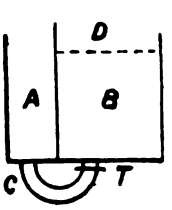

Fig. 1.

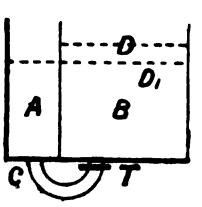

Fig. 2.

means of the tap, T. I fill the compartment B with water to the level D keeping the tap, T, closed. I open the tap, T, and immediately the water flows into A till the level of the water is the same in A and B, Fig. 2. The water then comes to rest. We started with the level of the water in B higher than the level of the water in A, we stop with the water in both compartments level. There was a flow of water, call it a current of water, from B to A, while the level of the water in B was highest. I want to obtain a continuous flow, and to do this introduce a small pump, P (Fig. 3). By continually pumping I keep the level of water

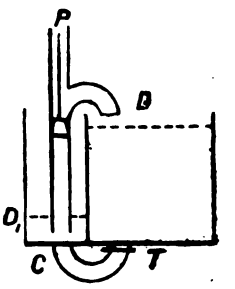

Fig. 3.

in A at D_1, and that in B at D. The water is too clear: you cannot see any water current, though you know it must be there because I am pumping, and yet the level in A gets no higher and no lower, so that what I pump out must be continually replaced from B. I drop a little colouring matter into B, and now you see it passing from B to A, and the coloured water by the pump is brought back to B. I might keep on this little game the whole evening, but shall probably find something better to do. I want you to notice that in this last experiment we have:

1. A piece of apparatus to keep up a difference of level, giving us thereby a difference of pressure.
2. An all-round channel or path.

You will easily see that without some such continuous channel the experiment would soon come to an end. It does not matter if the channel is very roundabout: it must be there. Instead of using a pump, I may let the water run out of B, and keep that in A at a constant level by getting water from the town mains. The continuity, however, can still be traced.

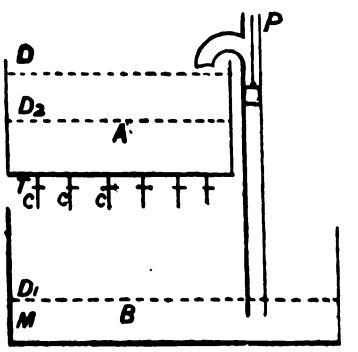

Fig. 4.

I have still another experiment with water to show you. Upon this stand are two more cisterns, Fig. 4. The upper one, A, is furnished with a number of escape-pipes, C, C, C, each with its tap, T. Each pipe is similar in all respects. The water in A stands at the line D, and there is no water in B, the cistern underneath. I open one escape-pipe and let the water flow for one minute. B has now water to the point M. I pour this water back to A, and, replacing B, open two pipes. Watch how long it takes the water in B to rise to M. There it is, and the time is half a minute. We will then assume that under the same head of water—that is, with the same pressure acting, the pipes being similar in all respects—equal currents of water will flow through them in equal times. If we replace the water once more, and instead of B put these two vessels to catch the water, one under each escape-pipe, turning on the water for half a minute, we find equal quantities in the vessels, proving what I have just stated to be correct. I replace the water and open one pipe only, letting it run for half a minute. You see there is practically the same amount of water in it as when both pipes were running. This shows that the opening of a second pipe does not interfere with the current of water flowing through the first. In the experiment this is not absolutely correct, because there has been a little difference in the head of

Digitized by Google

water in the two experiments; but you may take it from me, or try it for yourselves, that keeping the head or pressure constant the same quantity of water will flow through pipe No. 1 in equal times whether the other pipes are open or not.

There is just one other experiment I would like to show you. Instead of the level of water at starting in A being at D, suppose it is at D_2. Opening one pipe, and letting the water run for half a minute, we see that less water has run than when the level was higher. Further experiments might be made to show that the higher the level—that is, the greater the pressure—the greater would be the flow in a given time, and the less the pressure the less the flow.

There are other experiments which I might show you, but I think the results will be quite clear if I merely mention them. If I lessen the area of the escape-pipe, the rate of flow with a given pressure will be less than if I increased that area. In fact, by doubling the area—that is, by using the two pipes—I doubled the rate of flow. I can also decrease or increase the rate of flow by largely increasing the length or decreasing the length of pipe, for the pipe offers some resistance to the flow, and increasing the length increases the resistance offered, and so diminishes the rate of flow.

So that doubling area, with length of pipe and pressure constant, means doubling the current flow. We thus say current flow under these conditions is *directly* proportional to area of channel, path, or pipe; while it is *inversely* proportional to length of pipe, which, to repeat, means that the current flow increases or decreases as the area increases or decreases, other things remaining the same, and that that current flow decreases as length increases, and increases as length decreases, other things remaining the same.

It will not hurt to recapitulate what has been shown:

Then, first, to keep up the pressure, if we want a continuous flow we must somehow or other have a piece of apparatus to keep the water at the original level.

Second, we must somehow have an all-round channel, or path, or pipe, to enable us to retain the pressure.

Thirdly, keeping the pressure constant, increasing the number of channels, paths, or pipes, does not interfere with the current flow in any one channel.

Fourthly, the rate of current flow per channel or pipe depends upon the pressure. The total quantity depends also upon the number of channels or pipes.

Unfortunately, I cannot show you a current flow of electricity like I can a current flow of water. In the matter of current flow of electricity we must judge by its effects.

Here is a battery, some binding screws, some coils of wire, and a galvanometer. The battery is a piece of apparatus which serves to produce and, under proper conditions, maintain a difference of electrical level, and thereby we obtain electrical pressure. The galvanometer is an instrument the needle of which is moved under the influence of an electric current flow in the wire wound around it. This other wire is to make a continuous path for the electric current flow (hereafter to be briefly called "current") from one side of the battery to the other. I will throw a shadow of the galvanometer needle upon the screen, so that you can more easily trace its movements. In the diagram (Fig. 5) S_1, S_2, S_3, and S_4 indicate binding screws.

1. I have made all the connections, and you see the

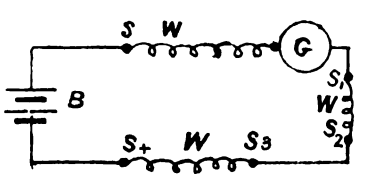

Fig. 5.

needle at once moves as I make the last connection to complete the continuous path. I sever the connection and the needle goes back; I make it again and it moves forward. Thus you will see that as soon as the path is made continuous we have indications of a current, and we cannot get these indications unless the path is continuous. The path of an electric current we call the *circuit*. I have here a coil of wire of the same length as that between S and the galvanometer, but of much larger sectional area. Notice well where the needle stands now.

2. I replace the original wire at S by this of larger area, and note the galvanometer needle swings further than it did before.

3. Putting back the original wire at S, and replacing that at S_1 S_2 by the thick wire, the needle swings to the same position as in the previous experiment—viz., No. 2.

4. Replacing original at S_1 S_2, and putting the thick wire between S_3 S_4, the needle swings to the same point as in 2 and 3.

You see, it does not matter where I alter the circuit. The same effect is obtained so long as the alteration is the same.

5. I now change the original coils for three coils the same length, but of greater sectional area, and you see the needle swings further than ever.

We have said that the needle acts under the influence of the current. The larger the current the further the needle swings, so that experiments 2, 3, and 4 indicate a larger current than experiment 1, and experiment 5 a larger current still. We may assume all through that the pressure has been the same, and that the larger current was obtained by diminishing the resistance of the circuit.

When the circuit consists of one continuous path it is said to be a *simple* circuit.

Let us return once more to experiment No. 1. Note the swing of the needle and the point where it comes to rest, or its deflection.

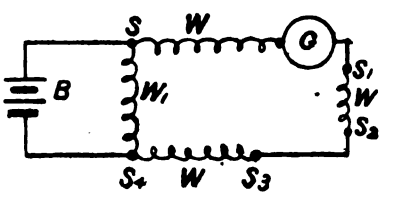

Fig. 6.

6. I have a fourth coil of wire exactly similar to the others, and I insert this between S S_4, Fig. 6. You see there is very little change in the position of the needle.

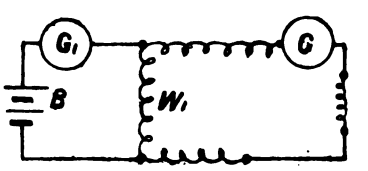

Fig. 7.

7. To find out a little more of what goes on I put a second galvanometer in the circuit, as shown in Fig. 7, and though this galvanometer is similar in all respects to that used all along, we see that the needles of the two galvanometers do not come to rest in the same direction. The galvanometer, G_1, shows a larger deflection than that at G, because the current that goes through both branches acts on G_1, while only the current that goes through one branch acts on G.

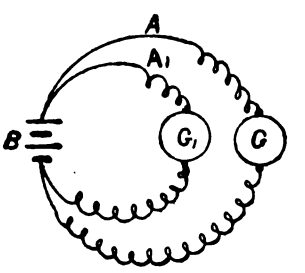

Fig. 8.

8. I now put a galvanometer in each branch circuit, and have made the resistances of the branches, A A_1 (Fig. 8) as nearly similar as possible. You see the needles of each galvanometer swing to the same point, showing that they are influenced by equal currents. The *total* current is double that in either branch.

9. If I alter the resistance of either branch—say, A_1—by putting in a thicker or a thinner piece of wire of equal

Digitized by Google

length I increase or decrease the current through that branch, as shown by the swing of the needle, while the current in the other branch, A, remains practically steady.

When the *circuit* consists of two or more branches, it is said to be a *divided* circuit.

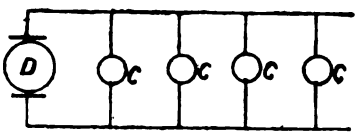

FIG. 9.

Usually incandescent electric lighting is by means of divided circuits, as shown in Diagram 9, where D is the dynamo and C C C the incandescent lamps. Such lamps are said to be in parallel.

CITY AND GUILDS EXAMINATION.

The following were the questions given at the examination last May. The syllabus of these examinations was given in our issue of August 31.

ELECTRIC LIGHTING AND POWER TRANSMISSION.

PRELIMINARY EXAMINATION.

The number of the question must be placed before the answer in the worked paper. Not more than eight questions to be answered. Three hours allowed.

1. Define the terms "in parallel," "in series," "on open circuit," and give sketches in illustration.
2. Describe the Leclanché cell, and add some hints as to how to maintain it in working order.
3. Sketch the connections needful for bells between two places, A and B, so that a person at B can ring the bell at A, and that a person at A can ring the bell at B. One battery (of two or three cells) only to be used, and only one bell to ring at a time.
4. A lamp circuit is supplied at a pressure of 100 volts. There are 42 lamps all in parallel, and the resistance of each lamp is (when hot) 150 ohms. How much current will the circuit take when all the lamps are on?
5. How can you convert a bar of iron into a magnet? If you have a small electromotive force, and no appreciable resistance in the rest of the circuit, would you use thin wires or thick for winding an electromagnet?
6. If electric bells are to be made to ring (by a magneto-ringer) through a line many miles in length, why must fine wire be used both in the coils of the ringer and in the coils of the electromagnet in the bell?
7. Why is there a permanent steel magnet in the bells that are to be used with magneto-ringers?
8. Describe shortly the construction of a glow lamp. Why does the filament become hotter than the platinum leading-in wires? Why does the globe of a bad lamp get very hot?
9. How many horse-power is required to drive a current of 100 amperes through a resistance of 7½ ohms?
10. State the principles on which the Cardew voltmeter is based.
11. Name the principal parts of an arc lamp, and say what is the use of each part.
12. Define "work" and "power." How many foot-pounds of work will be done in 20 minutes by a motor working at 4 h.p.?

ELECTRIC LIGHTING AND POWER DISTRIBUTION.

In the honours grade the student may, during the examination, use an electrical engineering pocket-book, but if he avails himself of this, he must state the title of the book on his answer paper, and in his answers give references to the pages of the book he has consulted. The number of marks obtainable is the same for each question.

ORDINARY GRADE.

(Not more than six of the following questions to be answered.)

1. Describe and sketch some form of ampere-meter of a type which does not depend on the magnetisation of iron.
2. A straight wire carrying a continuous current of 500 amperes lies at right angles to the magnetic flux in a field the intensity of which is 10,000 lines per square centimetre. State the force, in pounds, per foot of the wire tending to produce lateral displacement.
3. Give sketch to one-fourth full size of a switch for breaking an alternate current of 20 amperes at 2,000 volts.
4. State relative advantages and disadvantages of the two following systems of distributing alternate currents: (*a*) transformers in consumers' houses; (*b*) transformers in sub-stations.
5. Give full-size hand sketch of a commutator 6in. diameter, 4in. face, showing in section how the plates are supported and insulated.
6. Current is required along a street 2,000ft. long at the rate of one ampere per 10ft. of frontage. Give sectional area of conductor so that the difference of pressure between any two lamps shall not exceed two volts in the following two cases: (*a*) the current being supplied at one end; (*b*) the current being supplied midway. [N.B.—The resistance of a copper bar 1,000ft. long and one square inch in cross-section may be taken at ·008 ohm.]
7. Explain numerically the relations between the dyne, the erg, the joule, the kilogramme, the British horse-power, and the metric (French) horse-power.
8. Sketch the connections of a Wheatstone's bridge, showing how it is connected to the resistance to be measured.
9. A Gramme armature, intended for a two-pole field, has 120 turns of conductor wound upon it. Give the total flux required through armature core if an electromotive force of 100 volts is to be induced at a speed of 1,000 revolutions per minute.
10. Calculate the number of ampere-turns of excitation required to magnetise, up to 14,000 lines per square centimetre, a soft ring, 20in. in mean diameter, made of round iron 1in. thick. [Assume permeability = 800.]
11. State the circumstances under which it is economical to work glow lamps above their normal voltage.
12. What rules govern the design of motor-generators? Upon what does the speed of them depend?
13. Describe and sketch some form of automatic cut-out for series arc lamps, and explain its working.
14. Give the number of storage cells required for a 100-volt private house installation. Also state maximum charging voltage, and say how many cells must be connected with the regulating switch.

HONOURS GRADE.

Candidates for honours must have passed in the ordinary grade. They may select their questions from one only of the following sections.

SECTION I.—ELECTRICAL INSTRUMENTS, ETC.

Answer questions No. 1 and 3 of ordinary grade, and not more than four of the following questions:

15. Two bars, each five square centimetres in cross-section, have their faced ends touching within a solenoid excited so as to produce a magnetic induction of 15,000 lines per square centimetre through the joint. Give, in pounds, the force requisite to pull them apart.
16. Give a diagram showing connections of a switchboard for three alternators intended to work in parallel four feeders and one exciting dynamo.
17. Why is a closed magnetic circuit not the best form for choking coils?
18. Sketch and describe an instrument for the commercial testing of the permeability of bars of iron of different brands.
19. Describe a method for testing transformer plates for iron losses.
20. What method would you adopt to ascertain very precisely the ratio between the capacities of a very large condenser and a very small one?
21. What do you know of the temperature coefficient of the magnetism of permanent magnets? In what way is it affected by the temper, the mode of magnetisation, the shape, or the prior treatment of the magnet?
22. Describe a modern form of supply meter for continuous currents?

Digitized by Google

23. What is meant by the coefficient of damping of a galvanometer? What is the ratio, in an undamped galvanometer, between the angle of the first swing and the angle of the deflection when it has become steady?

24. Describe the arrangements for shunting a galvanometer so that when it is shunted down the total resistance of the circuit in which it is shall not be thereby changed.

25. Describe some form of electrostatic voltmeter suitable for measuring voltages from 50 to 150 volts.

26. Describe a photometer for measuring the illumination given on the pavement by street lamps.

(To be continued.)

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

E.M.F.—WANTED, CORRECT DEFINITION.

SIR,—I read with much interest the article on the City Guilds of London Institute's preliminary examination on "Electric Lighting and Power Transmission," which appeared in your issue of the 7th inst. I am a little uncertain as to the true definition of the term "electromotive force," mentioned as follows: "The difference of electrical potential is the cause of electrical pressure, and, again, this pressure is proportional to the difference of potential, and by increasing or decreasing the latter you increase or decrease the former. Using the electrical terms, what I have called electrical pressure due to difference of electrical potential is technically called electromotive force. I prefer to use the term 'pressure.'"

In "Houston's Electrical Dictionary" I find that the following explanations are given: "Force, Electromotive.—The force starting electricity in motion, or tending to start electricity in motion. The force which moves, or tends to move, electricity. The term is an unfortunate one. Strictly speaking, electromotive force is not a force at all: at least, it is not a force in the Newtonian sense, where force is only that which acts on matter. The term 'electromotive force' is generally written thus: E.M.F. The unit of electromotive force is the volt. When electric induction takes place there results a change in the distribution of the thing called electricity, whereby a movement occurs that results in a positive and a negative charge. The cause which produces this movement is called the 'electromotive force.' There is an unfortunate want of uniformity at present in the use of the term 'electromotive force.' By some, the electromotive force is regarded as something which causes the difference of potential; by others, the electromotive force is regarded as being produced by the difference of potential; and by still others, electromotive force is regarded as the entire electric moving cause produced by any source, while anything less than this is called by them potential difference. Those who regard the electromotive force as the cause which produces the potential difference look on the electromotive force as acting within the source and maintaining a potential difference at its terminals."

Silvanus P. Thompson uses the term electromotive force in his "Elementary Lessons in Electricity and Magnetism" as follows: "The term 'electromotive force' is employed to denote that which moves or tends to move electricity from one place to another. For brevity we sometimes write it E.M.F. In this particular case it is obviously the result of difference of potential and proportional to it; just as in water-pipes a difference in level produces a pressure, and the pressure produces a flow as soon as the tap is turned on, so difference of potential produces electromotive force, and electromotive force sets up a current as soon as a circuit is completed for the electricity to flow through."

Mascart and Joubert, in their work on "Electricity and Magnetism," Vol. I., say: "In all cases, the difference of potential, $V_1 - V_2$, may be considered as producing the motion of electrical masses; it is often called the electromotive force."

Maxwell, in his "Elementary Treatise on Electricity," speaking of the potential differences which may be shown to exist at the terminal of a Daniell voltaic cell when on open circuit, says: "This difference of potential is called the electromotive force of a Daniell cell."

Balfour Stewart, in his "Electricity and Magnetism, says: "This difference of electric level we shall call E, and, indeed, it is merely a manner of expressing the cause of electromotive force."

Prof. Fleming, in his "Short Lectures to Electrical Artisans," says: "The difference of electrical level or potential must be caused by some electromotive force acting in the conductor."

Prof. Anthony, in "A Review of Modern Electrical Theories," regards the potential difference as due to electromotive force. He says: "Difference of potential results from a changed electrical distribution, an electrical strain, and represents the tendency to return to the state of equilibrium. Electromotive force is the something from without that produced the electric strain."

Hering, in his "Principles of Dynamo-Electric Machines," says: "Difference of potential is, as the name implies, the difference of electrical potential between any two points of a circuit, and may, therefore, be applied to that at the poles of a machine, battery, or lamp, or at the ends of leads, or, in general, to any two points in a circuit. The term 'electromotive force,' however, applies only to the maximum difference of potential which exists in the circuit, or, in other words, the total generated difference of potential."

This last paragraph expresses the distinction between the two terms as ordinarily used in connection with dynamos and batteries.

As writers on the subject appear to be so extremely divergent in their opinions as to the definition of the term "electromotive force," I should be glad if any of your readers would give me the definition of the term as recognised by the "examiners," as I am thinking of entering for the above examination, and do not want to fall foul of my examiners.

STUDENT.

PRACTICAL APPLICATIONS OF PORTATIVE ELECTRICITY.

SIR,—I should like to relate an incident that happened to me, and it may be that one of your numerous readers will be duped in the same manner. The other day I visited a friend of mine near Manchester. I arrived by train, and was preparing to leave the station when suddenly I was heartily embraced by a pretty-looking young woman, who exclaimed: "My dear Charlie, you are here!" As my name is not Charles, and as the voice was quite strange to me, I was naturally very surprised. Well, profound apologies followed. She explained that she had mistaken me for her brother, whom she alleged I closely resembled, but later the same evening I missed my scarf pin, which was at least worth £4, and of special value to me as the gift of a friend since dead. A few weeks later I read in the papers of the same trick having been played upon another gentleman. Thus I was bamboozled in an original and daring but ingenious way. To prevent any further "mistake" by these charming thieves, I rigged up a small contact for my scarf pin, bought a tiny and neat electric bell (patented November 9, 1886, and November 27, 1888), made a double pocket accumulator, and now I am ready for any similar emergency. If the fair lady "mistakes" me again for her "brother" I shall at once hear the tell-tale of my pocket bell, and if it tinkles I will embrace (heartily) the "lady" (?) till a policeman releases me of the fair thief. I may add that I since carry about with me occasionally a whole "electric museum." The source of electricity is stored up in the said accumulators. I have made a contact for my watch; thus, if Bill Sykes, Esq. (!), tries to pull it out quietly the tell-tale indicates the fact at once. The third item of my practical equipment is a small incandescent lamp concealed in a well-finished artificial waterproof flower pinned to my coat. The lamp is useful during a performance at a theatre, when the light in the house is usually lowered, and when I may desire to look at the programme, etc. Another piece of apparatus invaluable for the inveterate smoker consists of a very fine platinum coil placed in a

Digitized by Google

cavity made of asbestos. By inclining the little tube the mercury in the same closes the circuit of my pocket battery, and I can thus light my cigar regardless of the weather. The entire museum weighs about 22oz., and the only bother is the recharging of the battery. The latest addition to my store is a hollow bamboo cane fitted with a tiny lamp provided with a small silvered reflector concealed in the knob. The hollow cane is sealed at the bottom by a rubber stopper, and the exciting fluid is $CrO_3 + HCl$. The cell consists of an amalgamated zinc rod and a strip of platinum sheet. This type of battery was used for Tissandier's "navigable" balloon. By inclining the cane the lamp is, of course, fed by an electric current, and gives a good light. Any intelligent person can rig up my "portative museum" in a few hours.—Yours, etc.,

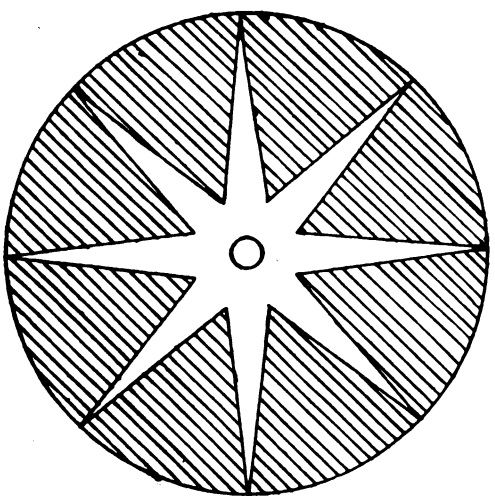
R. W. HILL.

Manchester.

TURNING DOWN ELECTRIC LIGHTS.

SIR,—I send you by this post a copy of the *Birmingham Daily Gazette* with an article in it on the subject of reducing the light emitted by incandescent lamps without resorting to the use of resistance, and trust the subject may be of some slight interest to you.

1. As to the cutting-off principle. I send you a tracing of the revolving disc, the shaded part of which represents the non-conducting part. Of course, the further away from the centre the brush is placed, so the light gets lower and lower.



2. As to the varied series principle. I never have any lights out—that is, not of necessity—and I may here remark that though the designing of the switches in the first instance gave me a great deal of trouble, when once made the copying of them is simple enough.

Of course, any plan which reduces the temperature of the filament reduces the candle-power at a greater rate than it reduces the amperage; but, apart from this inherent principle which is necessarily involved, the arrangements work very nicely, and the convenience and pleasure of being able to lower all the lights uniformly instead of turning some quite out and leaving a few bright points, will, I beg to submit, more than outweigh the unavoidable loss of candle-power in proportion to the power used.

Anyhow, the power consumed for the light given is infinitely less than when the usual resistances are resorted to.—Yours, etc.,

THOMAS BUDWORTH SHARP.

Birmingham, September 11, 1894.

[The enclosure in question is of very considerable length, and the following is an abstract thereof: The value of an easily applied method for lowering incandescent lamps was first brought under the notice of the inventor in a London hotel. On going to his bedroom he found a stocking (whether dirty or clean is not stated) had been carefully tied round the bulb of the electric light, and an investigation of the matter elicited the fact that many visitors, who were loth to sleep in utter darkness and did not want to have the full light, thus shaded it. Mr. Sharp's first idea was to place a make and break arrangement in the circuit. He constructed a small disc of metal conductors isolated by vulcanite, so that when the brush touched the metal a full current would be obtained, and when it came into contact with the vulcanite it would cease. The theory was that if a rapid revolution be made the filament will never get up to its full heat, on the one hand, nor be cooled down very materially, on the other. The disc could be operated by clockwork or otherwise, but as householders would not care to have to set a revolving wheel in motion, the inventor turned to another method. He determined to act on the principle that if the length of a filament of a lamp was increased or reduced, so would the intensity of the light become greater or less. He constructed two clusters of lamps, one of a pair of 16 c.p., and another of six lamps. The lamps are connected both in series and parallel, and switches are arranged so that the current can be run either way or shut off altogether. When the full light is required the current is switched on in parallel, and when a reduced light is required it is switched on in series. It is stated that the invention appears likely to revolutionise electric lighting.]

ALTERNATING-CURRENT DISTRIBUTION.

SIR,—Until Mr. Lowrie publishes the theory of the natural laws which he obeys in his transformer design, he must excuse me taking the same views as most other transformer designers. I must therefore stick to the opinion that the secondary current in his unique switch-transformer is due to an alternating field which will make the pole-pieces attract each other, and that, due to the presence of iron which makes the leakage path on opposite sides of the coils about equal, the repulsion and attraction between current and leakage field will very nearly counterbalance each other. The case is quite different for two solenoids without iron; then there are no pole-pieces to attract each other, and the leakage field on one side of the coil will be stronger than on the other, resulting in a repulsion.

As it is part of my daily work to design transformers and superintend their manufacture and testing, Mr. Lowrie need not inform me what happens when a transformer is short-circuited, but I am glad to see that we hold the same view. He says that "when the conditions require it, the short-circuit can be made through a resistance." I said that the result would be a burn-out "if the resistance of the coils were not high enough to keep the current within safe limits."

As to my letters having a disastrous effect on industrial development, it is my opinion that very much harm has been done, and is still being done, to the electrical trade by patentees receiving support for inventions which afterwards show themselves to be failures. I am, therefore, only too pleased to do my best to reduce the evil when an opportunity is offered, thereby supporting true progress.—Yours, etc.,

S. A. FABER.

September 11, 1894.

RE LARGE ELECTRIC CRANES.

SIR,—The following particulars of a large electric traveller may be of interest to your numerous readers. The crane was constructed for a load of 100 tons, and has three motors—one for each motion, lifting, travelling, and traversing. The girders are 7ft. deep and 74ft. span, and carry two crabs, so that when a finished locomotive, weighing 65 tons, is being lifted, one crab can be used at each end of the crane. A locomotive can be picked up and carried the whole length of the shop and deposited on the track in five minutes. The motors run at 500 revolutions per minute at a voltage of 220.

This crane, which I believe is *the* largest anywhere driven by electricity, is in the Baldwin locomotive works in America.—Yours, etc.,

GILBERT MILLINGTON.

St. Mungo, Belvedere, September 8, 1894.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIII. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

TURNING DOWN ELECTRIC LIGHTS.

On Sept. 6 the *Birmingham Daily Gazette* devoted over a column of its space to the discussion of this subject, and the description of apparatus devised by Mr. T. Budworth Sharp for attaining this object. Mr. Sharp has also written to us on the subject, and we have given his letter a place in our columns. Not for one moment do we wish to damp the ardour of inventors. They are necessary in these days and serve a good purpose, but too often their energies are ill-directed. It seems to us that Mr. Sharp has so misdirected his energies, and that though his apparatus may do all that he claims for it, he will find that its commercial value is a vanishing quantity. The energies of inventors may well be directed, broadly, into two directions—to devise something that is really wanted, or to devise something for which a demand may be created. In the matter of turning down electric lights, few even in the largest hotel, and fewer still in ordinary houses, require it. To accommodate these few every lamp in the hotel would have to be furnished with the means for turning down. Assume that half-a-dozen people in the hotel desire a light all night, will it appeal to the proprietors as so important that they will go to the expense of fitting a thousand lamps, say, with the necessary apparatus? We think not. The case is somewhat different in a large house with a nursery. Here a modified light is frequently burnt all night, and as this room is constantly used for one purpose the expense of fitting it up would not be great. By far the larger number of people do not care about lights always burning in bedrooms, and when they do want a light one of the great advantages of the electric light is that it can be turned on in a moment. Usually a switch by the bedside gives command of a lamp. For all ordinary purposes that is enough; the exceptions are more often than not caused by illness. But it is unnecessary to dilate further upon this part of the subject. Every reader can think it out for himself, and we shall be much surprised if the result of such cogitation is not towards our view — that the demand will not be commercially valuable. Nor do we think any demand can be created in this direction while an extra cost over and above the ordinary cost of installation is incurred for the necessary apparatus. Mr. Sharp describes two ways of attaining his object, one of which, the rotating commutator, may be put aside at once. It would involve clockwork, or an electric motor arrangement. In the former, someone would have to look after the clock, and this means wages, not to speak of initial cost. In the latter the current used to drive the motor would probably be more than was saved by the turning down the lamp, so there would be a constant loss, in addition to the initial cost. The other case would increase the initial wiring expenses, as both series and parallel wiring would be required. Therefore, taking into consideration, first, the lack of general demand existing or that can be created, and, secondly, the initial and continuous expenses, we are justified in thinking Mr. Sharp's energies to have been misdirected. We

Digitized by Google

must insist upon the fact that only in one bedroom out of fifty or a hundred would the modified light be required; but which room that would be no one could know. It is hardly to be expected that the manager of an hotel will have one wing with rooms where the modified light can be had, and ask his clients when they present themselves if they require a modified lamp at night or not, and give rooms according to their answers. We have made Mr. Sharp's design the text of this article not from any desire to speak well or ill of this particular invention, but to once more point out that inventors multiply inventions to no good purpose. So far as our experience goes, it is only for theatrical purposes that raising and lowering lights is generally required. We have always insisted that one of the greatest advantages of the electric light was that it could be put out and turned on as wanted. It is here where economy comes in, and assists in extending the use of electricity for lighting where, if it was necessary to run continuously at full load or modified candle-power, it would not find favour.

E.M.F.

What is the definition of E.M.F., is the question of a "Student"—that is, the definition to satisfy an examiner. It really does seem peculiar that at this stage of electrical knowledge such a question could be possible; yet the divergent views of authorities are put forward to show that it is not an unwarranted question. In order to see the latest definition, we turn to Vol. I. of a "Laboratory Manual of Physics and Applied Electricity," by Prof. E. L. Nicholls, just received from the publishers, Messrs. Macmillan and Co. On pages 181-2 Prof. Nicholls says: "Any generator of electricity, whether it be a battery, dynamo, or electrical machine, is capable, when energy is supplied to it, of *maintaining* a difference of potential between its terminals, even though they are connected by a conductor. It is to this capability of maintaining a difference of potential that we apply the name *electromotive force*." The italics are the author's. Had we italicised any words, they would have been others, and especially the word *capability*. We asked advice and information from an authority as to what would please examiners and gain full marks. His reply was pertinent and to the point: "First find out if the examiner has written a book. If he has, he wants to sell it; and the examinee should learn up that book, no matter what his private opinions are." The advice is good for the student, but we want to know for other reasons what is the accepted definition of E.M.F.

THE LATE PROF. HELMHOLTZ.

Hermann Ludwig Ferdinand Helmholtz was born August 31, 1821, at Potsdam, where his father was a professor in the gymnasium, his mother, Caroline Penn, being an Englishwoman. The family was not wealthy, and the future man of science was obliged to prosecute his studies as best he might while discharging the duties of an army surgeon. When 27 years old he was appointed assistant in the Anatomical Museum of Berlin, and in the following year he became professor of physiology at Königsberg. In 1856 he went to Bonn as professor of anatomy and physiology, and in 1859 he removed to a similar position in the University of Heidelberg, where he did a large part of his physiological work. Twelve years later he was made professor of natural philosophy in the University of Berlin, a post which he held until his death.

Helmholtz was accustomed to refer to his medical education as having given him valuable insight into natural laws and having laid the foundation for all that he subsequently did. Yet for the possession of a rude and imperfect microscope he was indebted during his career as an army surgeon to an attack of fever, his stay in the hospital permitting the accumulation of his salary. It was while performing the routine duties of this post that he produced his classic work on the "Conservation of Energy," a short essay which has done more than any but scientific workers can fully appreciate to stimulate the researches which have transformed modern science; for it is not only a statement of scientific fact, but a critique of all work in physics. The principle so luminously and forcibly set forth by Helmholtz has made itself felt as a co-ordinating and harmonising force over the entire field of scientific research. That as a matter of strict chronology he was to some extent anticipated by Joule and Mayer hardly detracts from the greatness of his achievement.

Helmholtz brought to his physiological work an unrivalled grasp of physical laws. Indeed, the special note of this great master was that he was an accomplished specialist in many different fields, and possessed the power of combining sciences for the attainment of results not attainable by any other means. His two great works on "Physiological Optics" and the "Sensations of Tones" exhibit him in the character at once of physicist, physiologist, and mathematician. When he turned his attention to optics the knowledge at the disposal of the oculist was extremely limited, at all events on the physical side, nor was its practical application to the complex structure of the eye by any means well understood. By the invention of the ophthalmoscope, Helmholtz substituted direct observation for conjecture, and by his analysis of the physical principles involved he raised observation to the higher level of science. At the same time he threw a new light upon the whole conditions of sensation and of voluntary motion in general. The same comprehensive yet penetrating analysis was brought to bear upon the sensations of tone, while the foundations were laid for the researches into the minute mechanism of the ear, which are among the most intricate and beautiful physiological works of the day. In acoustics as in optics, the work of Helmholtz ranges from mechanics on one side to psychology on the other. In dealing with the vibrations which form the physical basis of sound and light he wielded all the resources of the physical investigator; in working out the operation of these waves upon the sensitive structures of eye and ear the most refined physiological methods were brought into play; while in finally dealing with the translation of these physical and physiological facts into consciousness he showed himself an acute and accomplished metaphysician.

In every department of work at all closely related to his central studies Helmholtz has given evidence of his extraordinary fertility and strenuous energy. His scientific papers upon a wide range of physiological, chemical, physical, mechanical, and mathematical questions are invariably marked by the greatest breadth of view and the most direct insight into what is essential. In the catalogue of the Royal Society he is credited with more than a hundred papers of the highest importance, while of minor work in the form of popular lectures he was also prolific. His more recent researches upon vortices and the mechanical conditions governing the movements and distribution of the atmosphere show his intellectual vigour unimpaired by advancing years. He has long occupied an unquestioned position and enjoyed a European reputation. Recognition of his eminence has been freely accorded from all quarters,

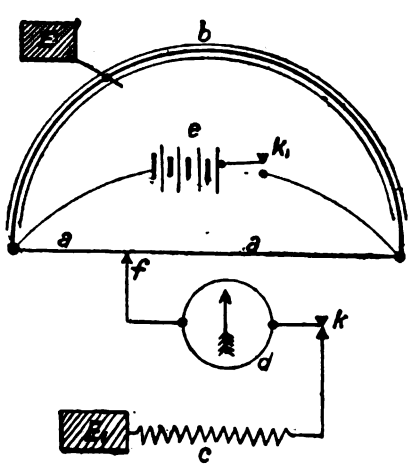
Digitized by Google

but of the numerous distinctions showered upon him we need mention only the Copley medal of the Royal Society, bestowed in 1873, and the fact that 10 years later the German Emperor raised him to the ranks of the hereditary nobility. Apart from his scientific work the life of Helmholtz has been calm and uneventful. After his marriage he dispensed a gracious hospitality in his official residence at Berlin, and he was all his life a genuine lover of the arts whose physical basis it was his great work to establish. One may without impropriety figure him as occupying in science a position not unlike that of his great countryman, Goethe, in literature. Breadth, universality of comprehension and sympathy, and a certain unmistakable intellectual serenity are characteristic of both.—*The Times.*

A METHOD OF FAULT-CURRENT ELIMINATION.

BY H. D. NORMAN.

The difficulties in the way of an accurate loop test caused by fault or cable currents are well known to everyone who has had much experience in cable work. The method most usually employed is that of neutralising the core under test with a moderately powerful current applied in opposition to that coming from the fault and making the final adjustment on the bridge as quickly as possible—*i.e.*, when the core is in a neutral condition. But it frequently happens, especially in the case of armoured cables,



that there is practically no neutral period, the cable simply passing from + to −, or *vice versâ*, and not stopping at zero at all; and it is with the object of doing away with this objection that the writer has devised the following modification of the loop test: in the diagram, *a* is the stretcher wire of a metre bridge or potentiometer; *b* is the faulty core; *c* is a high resistance, say, one megohm, in series with the galvanometer, *d*; *e* is a battery of well-insulated cells; *k*, the galvanometer key; k_1, the battery key. It will be seen on looking at the figure that the only difference between this and the ordinary loop test connections lies in the 1 Ω between the galvanometer and earth, E_1. The method of taking the test is as follows:

1. Depress *k* and obtain deflection due to fault current, and note: this will be the false zero to which to balance in future.

2. Keeping *k* down, depress key, k_1, and move contact, *f*, of galvanometer until balance is obtained at the false zero, then this point represents by a simple proportion the position of the fault on *b*.

In one experiment an artificial fault was made by means of a No. 2 Leclanché cell zinc rod, which fault gave an E.M.F. of ·67 volt, but the test was made with absolute accuracy.

The chief advantages of the modification are that any length of time can be allowed for accurate adjustment, and that the only path through which the current due to the fault E.M.F. can flow has such a high resistance that no variation takes place.

PRACTICAL NOTES ON DYNAMO CALCULATION.*

XI.

BY ALFRED E. WIENER.

(Continued from page 276.)

25.† *Types of Armature Winding—(a) Closed-Coil Winding and Open-Coil Winding.*—If, in a continuous-current dynamo, the reversal of the current would take place in all the conductors at once, considerable fluctuation of the E.M.F. would be the result. In order to obtain a steady current the armature conductors are therefore to be so arranged, relative to the poles, that a portion of them is in the strongest part of the field, while others are exposed to a weaker field, and some even are in the neutral position.

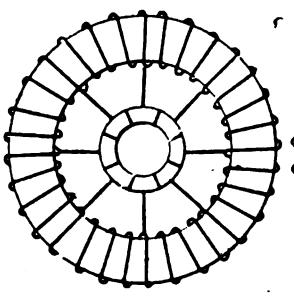


Fig. 32.

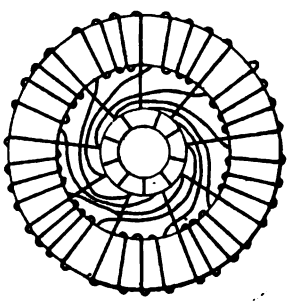

Fig. 33.

After having thus arranged the conductors, their connecting can be effected by one of the following two methods:

(1) All conductors are connected among each other so as to form an endless winding, closed in itself, and consisting of two or more parallel branches, in each of which all the single E.M.F.'s induced have the same direction, and in which the reversal of the current occurs in such conductors only that at the time are in the neutral position. An armature with such connections is called a "closed-coil armature."

(2) The conductors are joined into groups, each group containing all such conductors in series which, relative to the field, have exactly the same position; and the current is taken off from such groups only which at the time have the maximum, or nearly the maximum, E.M.F., all other groups being at that time cut out altogether. An armature wound in this manner is styled an "open-coil armature."

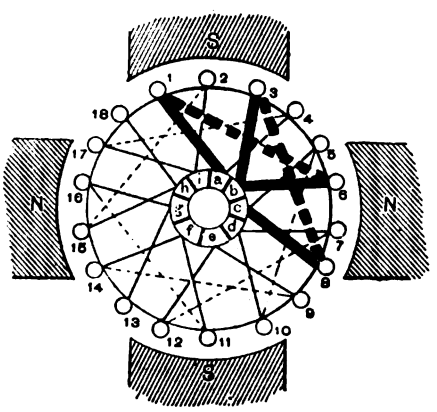

Fig. 34.

(*b*) *Spiral Winding, Lap Winding, and Wave Winding.*—According to the manner in which the connecting of the conductors by the above two methods is performed, the following types of armature windings can be distinguished:

* From the *Electrical World* (New York).

† *Errata.*—In section 24, page 276, of the last issue, the simplified form of the attraction formula in C.G.S. units should read $= G' \times \frac{\mathfrak{N}_1'^2}{16\pi}$; in formula (60) same page, the term $\left(\frac{\mathfrak{N}_1'}{6{\cdot}45}\right)^2$ should be replaced by $\left(\frac{\mathfrak{N}_1}{6{\cdot}45}\right)^2$; Figs. 22 and 24, same page, should be exchanged; Fig. 22 is intended for a horizontal machine and should be in a horizontal position, in place of Fig. 24, and *vice versâ*.

Digitized by Google

(1) spiral winding, or ring winding, Figs. 32 and 33; (2) lap winding, or loop winding, Figs. 34 and 45; (3) wave winding, or zigzag winding, Figs. 36 and 37.

In the spiral winding, Figs. 32 and 33, which can be applied in the case of ring armatures only, the connecting conductors are carried through the interior of the ring core, and the winding thus constitutes either one continuous spiral, Fig. 32, from which, at equal intervals, branch connections are led to the commutator, or a set of independent spirals, Fig. 33, which are separately connected to the commutator.

The lap winding, as well as the wave winding, is executed entirely exterior to the core, and can be applied to both drum and ring armatures.

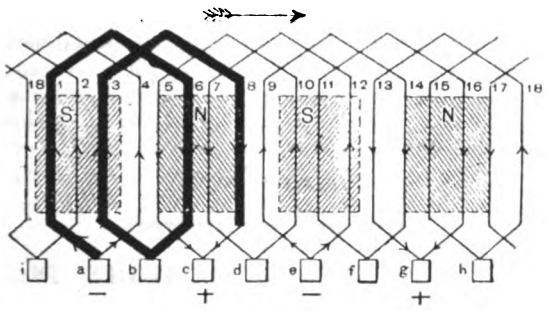

FIG. 35.

In the lap winding, Figs. 34 and 35, the end of each coil, consisting of two or more conductors situated in fields of opposite polarity, is connected through a commutator segment to the beginning of a coil lying within the arc embraced by the former. With reference to the direction of connecting, therefore, the beginning of every following coil lies back of the end of the foregoing, and the winding consequently form a series of loops, which overlap each other. Fig. 34 represents such a lap winding for a four-pole drum armature, the development of which, Fig. 35, more clearly shows the forming of the loops and the manner of their overlapping.

In the wave windings, Figs. 36 and 37, the connecting continually advances in one direction, the end of each coil being connected to the beginning of the one having a corresponding position under the next magnet pole, and the winding, in consequence, represents itself in a zigzag or wave shape. The wave winding is illustrated in Fig. 36, and for better comparison the same four-pole drum armature is chosen—that in Fig. 34 is shown with a lap winding. The development given in Fig. 37 distinctly shows the zigzag form of the wave winding.

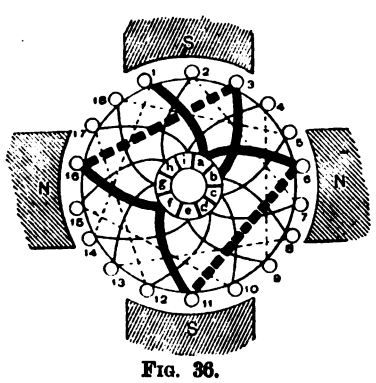

FIG. 36.

In multipolar machines, the wave winding can be used for series as well as for parallel connection; the lap winding, however, for parallel grouping only.

While the lap winding necessitates as many sets of brushes as there are magnet poles, the wave winding for any number of poles invariably needs but two sets of brushes.

For series-parallel connection, either wave winding may be used or lap and wave windings may be combined. Figs. 38 represents the development of such a "mixed winding," the coils partly being connected in the lap and partly in the wave fashion. This winding, like the wave winding, has the peculiarity of requiring but two sets of brushes, independently of the number of magnet poles.

26. *Grouping of Armature Coils.—Formula for Connecting.* A general formula for connecting the conductors of a closed-coil armature has been given by Arnold* as follows:

If K = number of conductors arranged around armature core;
a = number of conductors per commutator segment;
b = number of bifurcations of current in armature;
$b = 1$, single bifurcation, or 2 parallel circuits;
$b = 2$, double „ „ 4 „ „ etc.
P = number of pairs of magnet poles;
y = "pitch," or "spacing" of armature winding—*i.e.*, the numerical step by which is to be advanced in connecting the armature conductors;

then the number of armature conductors can be expressed by

$$K = a \times (P \times y \mp b),$$

from which follows the connecting formula for any armature:

$$y = \frac{1}{P} \times \left(\frac{K}{a} \mp b\right). \quad . \quad . \quad . \quad . \quad (63)$$

The general rule, then, for connecting any armature is:

"Connect the end (beginning) of any coil, x, of the armature to the beginning (end) of the $(x+y)$th coil."

For the various methods of grouping the armature coils the above formula is applied as follows:

(*a*) *Parallel Grouping.*—In this method of connecting there are as many parallel armature branches as there are poles—viz., 2 P circuits, or P bifurcations. Spiral winding, lap winding, and wave winding may be applied.

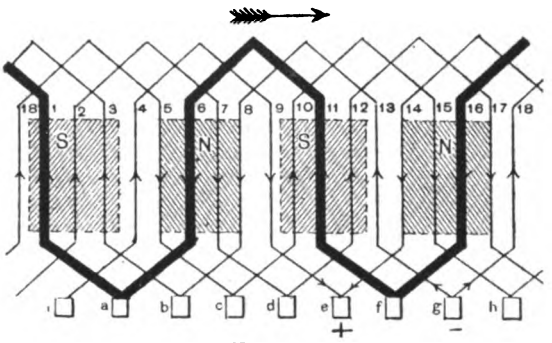

FIG. 37.

(1) *Spiral Winding and Lap Winding.*—In this case the multipolar armature is considered as consisting of P bipolar ones, and independently of the number of poles, P = 1 and $b = 1$ is to be inserted in (63), and the formula applied to a set of conductors lying between two poles of the same polarity.

(2) *Wave Winding.*—Here the actual number of pairs of poles, P, and the actual number of bifurcations, $b = P$, is to be introduced in (63), and the formula applied to the entire number of conductors.

(*b*) *Series Grouping.*—This is characterised by having but two parallel armature circuits, or one bifurcation, no matter what the number of poles may be; for series connecting, therefore, we have $b = 1$.

In the special case of P = 1, bipolar dynamos, the series connecting is identical with the parallel grouping, and the winding may be either a lap winding (spiral winding) or a wave winding; the latter holds good also for P = 2—*i.e.*, for four-pole machines. For dynamos with more than four poles, P > 2, however, series grouping is only possible by means of wave winding.

(*c*) *Series Parallel Grouping.*—In the mixed grouping the number of bifurcations is greater than 1, and must be different from P, hence in the connecting formula we have $b > 1$ and $b \gtrless P$.

In this case there are either several circuits closed in itself, with separate neutral points on the commutator, or one single closed winding with b parallel branches. The latter is the case if y and $\frac{K}{a}$ are prime to each other; the

* E. Arnold, "Die Ankerwicklungen der Gleichstrom Dynamomaschinen," Berlin, 1891.

Digitized by Google

former if they have a common factor. This factor, then, indicates the number of independent circuits.

27. *Application of Connecting Formula to Special Cases.*—(*a*) *Bipolar Armatures.*—(1) For any bipolar armature the number of pairs of poles, as well as the number of bifurcations, is = 1. Furthermore, the number of coils per commutator bar is usually = 1. Consequently $a = 1$, if in the connecting formula the number of conductors, K, is replaced by the number of coils, n. For ordinary bipolar armatures, therefore :

$$P = 1, a = 1, b = 1 ; \ldots\ldots y = n \mp 1 \quad . \quad . \quad (64)$$

(2) If the number of commutator segments is half the number of armature coils—*i.e.*, two coils per commutator bar—then

$$P = 1, a = 2, b = 1 ; \ldots\ldots y = \frac{n}{2} \mp 1 \quad . \quad . \quad (65)$$

(*b*) *Multipolar Armatures with Parallel Grouping.*—(1) By multiplying the bipolar method of connecting, we have :

$$P = 1, a = 1, b = 1 ; \ldots\ldots y = n \mp 1 \quad . \quad . \quad (66)$$

This is a spiral winding; beginning and end of neighbouring coils are connected with each other, and a commutator connection made between each two coils. The number of sets of brushes is 2 P.

For multipolar parallel connection and spiral winding with but two sets of brushes, either n divisions may be used in the commutator, and the bars, symmetrically situated with reference to the field, cross-connected into groups of P bars each, or only $\frac{n}{P}$ segments may be employed, and P coils of same relative position to the poles connected to each bar by means of P separate connection wires.

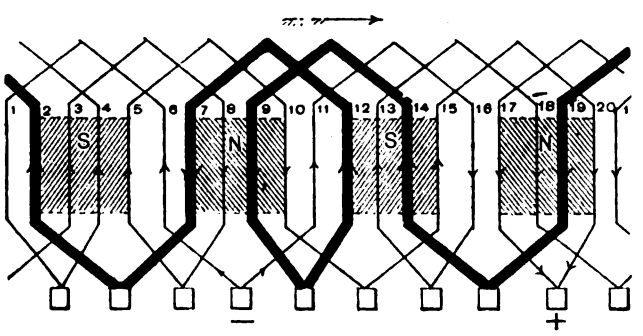

FIG. 38.

(2) In connecting after the wave fashion by joining coils of similar positions in different fields to the same commutator segment, the following formula is obtained :

$$P = P, a = 1, b = P ; \ldots\ldots y = \frac{1}{P}(\mp P) = \frac{n}{P} \mp 1 \quad (67)$$

If y and n have a common factor, this method of connecting furnishes several distinct circuits closed in itself, the common factor indicating their number.

(3) If P similarly situated coils are connected in series between each two consecutive commutator bars, only $\frac{n}{P}$ segments, but 2 P sets of brushes are needed; the winding is of the wave type, and the connecting formula becomes :

$$P = P, a = P, b = P ; \ldots\ldots y = \frac{1}{P}\left(\frac{n}{P} \mp P\right) = \frac{n}{P^2} \mp 1 \quad (68)$$

(*c*) *Multipolar Armatures with Series Grouping.*—(1) If all symmetrically situated coils exposed to the same polarity, by joining the commutator segments into groups of P bars each, are connected to each other, they can be considered as one single coil, and we obtain

$$P = P, a = 1, b = 1 ; \ldots\ldots y = \frac{1}{P}(n \mp 1) \quad (69)$$

Each brush in this case short-circuits P coils simultaneously.

The same formula holds good if beginning and end of every coil are connected to a commutator bar each. The latter can always be done if P is an uneven number; but if P is even, the number of coils, n, must be odd. In the case of P uneven, if n is even, the brushes embrace an angle of 180deg.; but if n is odd, an angle of only $\frac{180\text{deg.}}{P}$ is enclosed by the brushes.

2. Instead of cross connecting the commutator, the winding itself can be so arranged that only $\frac{n}{P}$ bars are required. In this case the connections have to be made by the formula :

$$P = P, a = P, b = 1 ; \ldots\ldots y = \frac{1}{P}\left(\frac{n}{P} \mp 1\right) \quad . \quad (70)$$

Note.—In drum armatures the beginning and end of a coil being situated in different portions of the circumference, they should be numbered alike, and yet marked differently, in order to facilitate the application of the above connecting formulæ. By designating the beginnings of the coils by 1, 2, 3, ..., and the ends by 1', 2', 3', ..., this distinction is attained.

(To be continued.)

THE USE OF STORAGE BATTERIES IN THE TROLLEY RAILWAY PLANT AT ZURICH, SWITZERLAND.*

The total length of this line is 4·6 kilometres (2·36 miles). The grades are quite severe, the maximum of 6·48 per cent. extending a distance of 378ft. The average grade is 1·1 per cent. The line is a single-track road, with the exception of eight turn-outs about 30 metres in length, as well as a short section of the track upon which the cars of the Central Zurich Berg road run. The gauge is less than that of the Zurich Street Railway Company, which operates with horses—namely, one metre (39·4in.) instead of 4ft. 8½in. The gauge of one metre is that generally adopted for new tramways, on account of its advantages over the other in narrow streets and on curves of short radius.

The type of rail used is the Phœnix 7 A, which has a weight of 77 kilogrammes per running metre of complete track (78lb. per yard). It is laid on a stone foundation without using the usual ties.

The cars are from the works of the Swiss Industrial Company, of Neuhausen. They have a capacity for seating 12 passengers and standing place for from 12 to 14 others without overcrowding. Each car is equipped with one four-pole Oerlikon electric motor of 18 h.p., which is mounted on the truck in the usual way well known in America. The gears run in grease. The speed and direction of the car are controlled by a controller on each platform operated by means of a lever and gears. The two controllers have a common resistance-box. The great disadvantage of the usual controlling apparatus consists in the fact that the arc, which in electric railways is usually caused upon the breaking of the current, acts very disastrously on the contact-pieces, and in a short time occasions their destruction. This is remedied by making the apparatus in such way that the sparking occurs only at one place, where it is "blown out" by a small electro-magnet specially provided and arranged for the purpose. The equipment includes the usual fuses and cut-out switches.

The total weight of the car, empty, with electrical equipment is about 4·10 (short) tons, or, including passengers, about 6·19 tons (of 2,000lb.).

With nine cars it is possible to operate on a headway of six minutes. This requires an average speed of 10·6 kilometres (6·57 miles) per hour, including stops. The trolley wire is of copper of seven millimetres (0·276in., about No. 1½ B. & S.) diameter, and is supported at a height of about 5½ metres (18ft.) above the street, so that it does not interfere with even the highest vehicles. Span wire (steel) or bracket construction is employed, the use of each depending upon local conditions.

The trolley wire serves for the outgoing circuit, the

* Abstracted from the *Street Railway Journal.*

Digitized by Google

rails being used for the return. The joints are bonded with copper bonds. A copper supplementary return of seven millimetres is laid between the rails and connected from time to time with the rail bonds, making a continuous return circuit. The outgoing circuit is divided into four insulated sections of about the same length, each supplied from the central station through a feeder of 60 square millimetres (about No. 00 B. & S.) cross-section. Guard wires are also employed to protect the trolley wires from falling telephone or telegraph wires. Most of the telephone wires are run underground.

The current is supplied by a generator and a battery of accumulators working in parallel, the batteries being placed between the engine and boiler rooms.

To understand the arrangement of the storage batteries it must be noted that the current load in stations of such small capacity undergoes uncommonly severe and quick fluctuations. It might happen that for a moment—namely, when perchance all the nine cars stop at one time—the current may fall down to zero, and possibly in the next moment it may jump to the maximum of 200 amperes. On the average, the current required is around 80 to 90 amperes. It is evident that such a variable load, without the help of storage batteries, must have the most deleterious influence on the efficiency of the dynamo and engine. On the other hand, by using storage batteries one can obtain the great advantage that the engine and dynamo load remain almost uniform. If the power consumption on the line rises above the capacity of the generating plant, then the storage battery assists the plant; if, on the contrary, the consumption falls below the capacity of the latter, the surplus of the current produced by the dynamo flows into the storage battery and charges it. The plant, therefore, runs at its normal capacity—that is to say, under the most favourable conditions possible.

In regard to the advantages of using storage batteries in parallel with the generator, the Oerlikon Works Company submits the following computation: "The average grade on the Zurich electric railway amounts to 1·1 per cent. The load of the car, including electrical equipment, amounts to about 3·8 (metric) tons. If we consider that the cars carry, besides the conductor and motor-man, on an average one-third of their total carrying capacity, which is not estimating it too high, the average total weight per car reaches 4·4 (metric) tons. Assuming the traction coefficient to be 12 kilogrammes per (metric) ton (24lb. per ton of 2,000lb.), the total round trip therefore requires $2 \times 4{,}600 \times 4{\cdot}4\ (11+12) = 931{,}000$ kilogrammetres. No account is taken of the reduced consumption on down grades.

"The complete trip, with all stops on the way and at the end, requires 52 minutes; therefore, with the allowance of 25 per cent. increase for starts and curves, this corresponds to an average output of $1{\cdot}25 \times \frac{931{,}000}{54 \times 60 \times 75} = 4{\cdot}75$ effective horse-power per car measured at the car axle.

"The average loss from the steam-engine to the car wheel can be taken at 35 per cent., and therefore the efficiency comes out 65 per cent.

"For a 12-minute run (five cars) we have therefore $\frac{5 \times 4{\cdot}79}{0{\cdot}65} = 36{\cdot}8$ h.p.; and for a six-minute run (nine cars) $\frac{9 \times 4{\cdot}79}{0{\cdot}65} = 66{\cdot}3$ h.p., which is the power required at the engine flywheel; or, per day, $36{\cdot}8 \times 1{\cdot}9 + 66{\cdot}3 \times 12{\cdot}9 = 925$ horse-power hours, for which a daily consumption of 1,350 kilogrammes (2,975lb.) of coal, or 1·46 kilos (3·22lb.), per horse-power hour is required.

"Power stations for electric railways without storage batteries consume for this output, as demonstrated by experience, 2·5 kilos (5·51lb.) of coal and more (per horse-power hour). In fact, there will be not less than 440 tons of coal saved per annum, while the cost for the maintenance of the battery scarcely exceeds one-seventh part of this amount saved."

The power station is equipped with the following apparatus: two vertical compound steam-engines, each of 90 h.p., operating at 240 revolutions per minute; two Oerlikon shunt generators of 66 kilowatts capacity (550 volts), operating at 450 revolutions per minute, belted to the engines. Of these two pairs, one only is usually in service, the other being held as a reserve. The idle pair can be put in service to relieve the other without interrupting the service of the station. It is, however, apparent that in case repairs to the storage batteries should be necessary the battery must be disconnected for a given time; in which case the reserve plant takes the place of the battery, and both machines, by switching in the compound coil, work as compound-wound dynamos. The storage battery is located in a special room, and consists of 300 Tudor elements No. 110, of 245 ampere-hours, and having a maximum current rate of 81 amperes. It is, however, possible, without shortening the life of the batteries, to double this current for a shorter time. The regulation of the charge or discharge of the batteries is effected by switching cells in and out of circuit by an automatic arrangement. In order to recharge these regulating cells and bring them up to the proper condition and make them uniform with the rest, a small direct-coupled generating unit is used, having a capacity of about three kilowatts, or 20 amperes at 150 and 30 amperes at 100 volts. It is found by experience that this small unit need not be operated continuously, but is only required to operate for an hour or two each day.

THE EQUIPMENT FOR ELECTRICAL ENGINEERING LABORATORIES.*

BY D. C. JACKSON.

When this subject was assigned to me by your secretary it was suggested that a discussion of the ideal equipment for the electrical engineering laboratories of engineering schools was not wanted. The discussion should be limited to the special electrical equipment that is necessary for use in engineering schools having a course in electrical engineering, in order that proper instruction may be given in their specialty to the undergraduate electrical engineering students. This seems to be a reasonable limitation, and, in fact, an essential one, if the discussion is to be of value. I doubt if anyone is able, with our present knowledge of the requirements, to outline the true ideal equipment for electrical engineering laboratories. We can all tell what we now consider an ideal equipment, but in a few years it may be far from ideal. We are, however, faced by a positive condition which demands a first class working equipment in the electrical engineering laboratories. How can the electrical laboratory equipment be made most effective, is a question for solution; how much and what equipment is required to fulfil the demand in the instruction, is another question which confronts us.

As we are are dealing with electrical engineering laboratories, we will presume that they are attached to the engineering department over which a professor of electrical engineering presides. The electrical engineering department is therefore separated entirely from the physics department, and is co-ordinate with the other departments of engineering. The practice at present common in many colleges of placing the electrical engineering course with its classroom and laboratory instruction under the direction of the professor of physics, is just as absurd as it would be to devolve upon that professor the instruction in advanced thermo-dynamics and the design and construction of steam-engines. It is equally absurd for the professor of electrical engineering to attempt to teach physics. Proper instruction in physics is essential to the student who is pursuing a course in electrical engineering, and the physics department must be well controlled and supplied with an excellent independent laboratory equipment. In addition to the ordinary general course in physics, the electrical engineering student should gain, during his course in physics, a common-sense grasp of the elementary notions of electricity and magnetism, and of the "all-pervading law of Ohm." The latter can be properly enforced in the laboratory by placing in the student's hands ordinary electrical instruments—such as galvanometers, bridges, voltmeters, ampere-meters, etc.

* Paper read before the Society for the Promotion of Engineering Education, at Brooklyn, N.Y., August, 1894.

Before beginning his work in electrical engineering, the student's knowledge of Ohm's law and its common results should have become almost instinctive. The student should also become acquainted with the theory and practice of photometry. This should all be done in the physics department, and the equipment required for the instruction should be controlled by that department. Much of this equipment is quite different from that required by the electrical engineering department, but some of it is useful to both departments, and where students are not too numerous may be used to some degree in common.

With due regard for his preparation, it seems best to arrange the professional electrical studies for the average electrical engineering student in four divisions, in three of which laboratory work must be made an integral part of the instruction in a satisfactory course. The divisions are: (1) electromagnetism and its applications to special uses, with special reference to dynamos and motors; (2) electrochemistry, including primary and secondary batteries, and electro-metallurgy; (3) alternating currents and alternating-current machinery, including alternators, transformers, motors, condensers, etc.; (4) the special application of the preceding divisions in electric light, power, railway, mining, telegraph, telephone, and other types of plants. These divisions are of about equal real moment, but the last must be allotted more time in the lecture-room than either of the others, but little or no laboratory time or equipment need be directly allotted to it. The laboratory equipment for the first three divisions only need therefore be discussed. The equipment that can be made useful in the fourth division is usually of an illustrative nature, and must be a matter of slow growth and collection as the electrical industries progress rather than immediate selection.

While higher mathematics is a useful aid in each of the divisions, its limitations as an agent must be carefully shown in the classroom and laboratory. For the purpose of educating the judgment of a student, and fully defining the limitations of theories and mathematical deductions, the laboratory is indispensable, and the equipment should be selected with this object in continual view. The equipment should be so selected and be of sufficient amount that as much as one-half of the total time spent by the student under the direct instruction of the professors of electrical engineering may be profitably devoted to the laboratory. The equipment, moreover, should be such that the work may as far as possible deal with fixed commercial instruments and machinery, and actually follow the methods of testing and research used in practice. The first three divisions should each be properly represented by a commercial laboratory equipment, in which every principle and operation is illustrated and made useful in every-day instruction under the direction of a man who has had experience in similar commercial work after having had a thorough theoretical training in preparation for his work. The laboratory work must always go hand in hand with the classroom work, illustrating and strengthening the latter. In this way the equipment may be made most effective in the work for which it is designed.

We will call the laboratory equipments for the three divisions, the dynamo equipment, the electrolysis equipment, the alternating-current equipment, and consider the essential equipment of each separately in the consecutive order given, since that is probably the best order for the student to take them up. It is well to remember at this point that engineering measurements are almost invariably quantitative, and that the results from an engineering investigation which bear fruit are also nearly always quantitative. It is seldom that purely qualitative results may be accepted as satisfactory in engineering work. Therefore the laboratory equipment must be capable of doing quantitative work which is, in general, of satisfactory commercial accuracy, and which may be made rigorously exact for purposes of exact investigation.

The first work that a student should take up upon entering the dynamo laboratory is a study of the methods of testing the magnetic qualities of iron. In this work, testing by magnetometer, ballistic galvanometer, and traction should be used. The apparatus for the magnetometric method is very simple and is generally at hand, as almost any reflecting galvanometer may be used for the magnetometer. For the ballistic method, a magnetising yoke and proper test-pieces should be supplied as well as a satisfactory galvanometer. Arrangements for determining the constant of the galvanometer and proper current-measuring instruments must be supplied. For the latter, Weston ampere-meters with proper scales and in good condition are entirely satisfactory. To determine the constant of the galvanometer, several methods requiring their own special but simple apparatus should be used. The special apparatus for the traction method of testing iron consists simply of a magnetising yoke with its test-pieces. Here, again, an ampere-meter is required. Indeed, a good supply of first-class ampere-meters and voltmeters is of the utmost importance in the electrical laboratory. These should be selected so that various types are represented, but for general use with continuous currents the Weston instruments are most satisfactory, and should therefore be in a majority. Ampere-meters, with scales from 0 to 1, 0 to 5, 0 to 15, and 0 to 50; voltmeters, with scales from 0 to 5, 0 to 60, 0 to 150, 0 to 600; and milliampere-meters and millivoltmeters are indispensable. The actual number of instruments required for use must depend, of course, upon the number of students who work in the laboratory.

In addition to the standard methods of testing iron which have been mentioned, there are several special devices constructed by different instrument makers which are of some advantage in instruction, but which should not be purchased until the essential equipment is supplied. Such are the iron tester using a bismuth spiral made by Hartmann and Braun, the Siemens and Halske device, and magnetic bridge arrangements.

It is not a bad plan to have various test-pieces for use with the ballistic method made from cast and wrought iron and cast steel of known chemical composition and degrees of annealing. These may be most conveniently in the form of bars to be used with the magnetising yoke, or may be rings. By using various specimens for the class testing a very good idea of the differences to be found in different bars is given to the students. In this work the students should always be required to plot both the curve of magnetisation and the permeability curve of his specimen, as well as to fully report his process.

After the testing for simple magnetic quality comes the measurement of the hysteresis loss and its companion—coercive force. For this purpose apparatus for the magnetometric method, with slowly varied continuous currents, should be provided. This may be similar to the apparatus for the magnetometric method of testing the magnetic quality of iron. If a sufficiently small number of students work in the laboratory, the same apparatus may be used. In addition to the magnetometric apparatus a couple of devices for testing hysteresis loss by alternating currents should be supplied. These methods are being improved so rapidly that it is almost impossible to say which are the best for fixed use in laboratory instruction, and much must be left to individual choice. Here, again there are various excellent illustrative but unessential pieces of apparatus, such as the Ewing curve tracer, which should only be purchased after the essential apparatus is fully supplied, or which really belong in the field of the department of physics.

The writer makes all his laboratory work follow quite closely to his classroom instruction, and therefore makes the work in the dynamo laboratory follow the plan of his text-book on "Electromagnetism and Continuous-Current Dynamos." Consequently, after the students have completed their work in magnetic testing, they begin a study of the dynamo. The dynamo-room must fulfil two objects: (1) to furnish current for experimental work which cannot be conveniently furnished from the laboratory lighting circuits; (2) to supply machines for laboratory testing. For the first purpose dynamos of various pressures driven by a steady power must be arranged so that they may be operated upon laboratory circuits as desired. This requires that a good automatic engine, which is used for no other purpose, be used to drive the dynamos, and that the machines be systematically wired to suitable distributing switchboards. A good storage battery of 60 or 70 cells is a most useful adjunct in this connection. For the second purpose it is

Digitized by Google

desirable to have continuous-current machines of comparatively small size—from 2 to 10 kilowatts capacity. Such machines are readily handled, are not readily injured, when injured are inexpensive to repair, and laboratory testing with the machines under load is always possible, when it would frequently not be so with larger machines. A dynamo laboratory in which a fair number of students work needs a number of such machines, which should be carefully chosen to represent the widest range of types and styles of construction. All these machines should be so arranged that they may be operated either as dynamos driven from a constant-speed prime mover, or as an electric motor.

Upon entering the dynamo-room for work the student receives systematic instruction in handling the dynamos so that his work may proceed without danger to himself or to the machines. Determinations of the strength of the fields of dynamos when the armature windings are known are then made from measured speeds and pressures. This requires no instruments except voltmeters and ordinary speed counters. Following this comes the measurement of leakage by ballistic methods, and a comparison of the measured results with results calculated from the dimensions of the machines. This gives the student an idea of the large percentage of guess which must enter into such calculations. Tests of the magnetic circuits of dynamos, the regulation of dynamos and motors with different forms of field windings, effect of load on lead, characteristic curves, etc., all require the all-useful ampere-meters, voltmeters, and speed counters, which, as already said, must be on hand in sufficient number and with a sufficient variety of range.

Efficiency testing requires a more varied equipment, yet in this the ampere-meter and voltmeter hold prominent places. In stray-power tests and determinations of the losses by hysteresis and Foucault currents in armature cores, ampere-meters, voltmeters, and speed counters supply all the information that is needed. Efficiency tests should always be made by stray power, live-load and dead-load methods. For the latter, convenient variable liquid, wire, and lamp loads should be liberally supplied. One or more first class bridges must be at hand for measuring resistances and standard instruments, such as Kelvin balances or Weston laboratory instruments, should be conveniently arranged for the calibration of the portable instruments. Stationary devices for the measurements of currents, such as a good calorimeter and a galvanometer arranged for use in the so-called Vienna method, should be properly mounted.

Recapitulating, the essential apparatus for the dynamo laboratory is: Appliances for testing the magnetic and hysteretic qualities of irons, together with the necessary test-pieces, galvanometers (plain and ballistic), standard solenoids, earth coil, condenser, etc. Set of small continuous-current dynamos and motors representing various types for laboratory testing. Goodly supply of first-class ampere-meters and voltmeters, of various types, with standards for use in calibration. Instruments for measuring currents by different methods, bridges, and special instruments for measuring resistances. Various arrangements for loading dynamos and motors, and testing their speed. A number of portable storage cells to furnish steady currents which cannot be conveniently supplied from the lighting circuits and the dynamo-room.

The electrolysis and alternating-current equipments will not be taken up in so great detail. The former requires for the fundamental work a number of standard cells, silver and copper voltameters, fine galvanometers, balances for weighing, accurate resistance boxes, devices for measuring the resistance and specific inductive capacity of electrolytes. For the advanced work is required a goodly supply of primary and secondary cells of various types which may be used in examination and testing, and a well-equipped set of two or three good sized electro-deposition vats and arrangements for heating by the arc, with low-pressure dynamos, and the ampere-meters, voltmeters, and hydrometers which are necessary to carry out work on a considerable scale in electro-deposition and electro-metallurgy. The electrolysis laboratory has received comparatively little attention in American engineering schools, but its importance makes it deserve an allotment of its full share of equipment and instructional force. There seems to be a time coming when the electrolysis equipment will be made equal in importance to the dynamo equipment in all first-class engineering schools.

The alternating current is receiving a preponderating amount of attention in many colleges, sometimes on account of the numerous striking and beautiful experiments which may be performed by the alternating current, and sometimes because of the attractive field of speculation which is opened by the use of polyphase currents in power transmission. It is not belittling the enormous power value of the alternating current to say that the equipment of each of the divisions should be given equal consideration, and no one should be given undue prominence to the injury of the others.

The effects of self-inductance, mutual inductance, and capacity are at the root of a large proportion of alternating-current phenomena, and the fundamental alternating-current equipment should be arranged for the study and measurement of inductances. It would be a long step in advance if electrical engineering graduates were given as lively and practical a working conception of inductance and reactance as that usually given them of Ohm's law and its results. For studying inductances in the laboratory, various coreless solenoids are needed, which may be used for experimental and mathematical determinations of the coefficients. The methods of measuring the inductances of solenoids should include the direct measurement of self-inductances by ampere-meter and voltmeter using an alternating current of known frequency, the comparison of self-inductances with each other and with mutual inductances, the direct measurement of mutual inductances by ampere-meter and ballistic galvanometer, the comparison of self and mutual inductances with capacities, etc. After these measurements have been carried out by the student, using the simplest known methods, the measurements should be extended to include circuits with iron cores. These measurements require comparatively simple apparatus, but it should be on hand in sufficient amount. Carefully-wound long and short solenoids of known constants, condensers of known capacity, bridges, alternating-current ampere-meters and voltmeters, a sensitive ballistic galvanometer, and a secohm-meter are essential for the work. A very convenient instrument for use in this branch of the work is a variable standard inductance, but its place may be filled by solenoids of known constants.

After inductances, the alternator and single-phase currents are in logical line. One or more small alternators are needed for this work, which may be carried out in much the same way as that relating to continuous current dynamos. The work, however, requires the introduction of two new instruments, the wattmeter and a device for taking alternating-current curves. Wattmeters are difficult instruments to get in satisfactory form, but probably the Weston form is the best for general laboratory use, though a split dynamometer is a good instrument to have at hand. There is a considerable number of schemes for the tracing of alternating current and pressure curves, and more than one should be put into use. The relations of the current and pressure waves in circuits should be studied from the curves, as well as from measurements of the true and apparent energy in the circuits. This study is finally applied to transformers, a number of which, representing various types of construction, should be in the equipment.

The laboratory equipment to be supplied for the study of polyphase current effects is as yet an open question. It seems desirable to have at hand polyphase currents of variable frequency and induction motors representing the different types of construction. The variable frequency polyphase currents may be most readily gained by means of a rotary converter.

The equipment which has been enumerated, or is necessary to carry out the experiments that have been mentioned, covers the essential requirements of any first-class undergraduate course in electrical engineering. There is much more work which must be carried out in the laboratory, such as testing the insulation resistance of wires, measuring the earth's magnetic force, accurately comparing standard resistances by divided wire bridge, etc., but the equipment for this is found in that already enumerated, or has its

Digitized by Google

place among the apparatus of a well-equipped physics department. There is much apparatus which is entirely unnecessary for both the physics and electrical engineering departments to possess. In fact, the work just mentioned, with the exception of insulation testing, really belongs in the instruction given by the professor of physics, and, as intimated earlier, it is well for the laboratories to be quite independent of each other. There is a vast amount of work carried on by undergraduates in the preparation of theses which is often in the nature of excellent investigation. Some of this requires special apparatus, and the extent to which it should be supplied from laboratory funds is an open question. Where the investigation does not require special apparatus, or where the work is in the nature of a test of commercial apparatus or an operating plant, the equipment that is required will nearly always be found among that supplied for the regular course, if the latter has been properly designed.

In determining the course of study to be pursued by the electrical engineering undergraduate, upon which the course of laboratory work must depend, it must, unfortunately, be remembered that he cannot confine his attention to electrical engineering during the whole time given to professional work in his course. He must gain an elementary but practical knowledge of thermodynamics and hydraulics, with an efficient knowledge of their application in steam and water power plants. He must also get a common-sense knowledge of the principles underlying the design, manufacture, and selection of machinery. In fact, he must receive a good working knowledge of the problems of the mechanical engineer. Laboratory courses are likely to fail when not properly balanced on account of a failure to educate the common-sense or judgment of students, and the students leave the college without having gained an all-round capacity for practical work and research which is necessary to put them in a fair way to become useful engineers. The knowledge of the electrical engineer must be based on the honest, well-tried mechanical laws, and he must go into a study of all that will aid most in putting him in a way to make a thorough electrical engineer.

THE "UNIQUE" SWITCHES.

We illustrate herewith some of the latest improvements in the "Unique" switches manufactured by Mr. A. P. Lundberg, Bradbury-street, Kingsland, N. The switch shown in Fig. 1 is now made in four sizes up to 20-ampere capacity. In the smallest size of switch the key is of

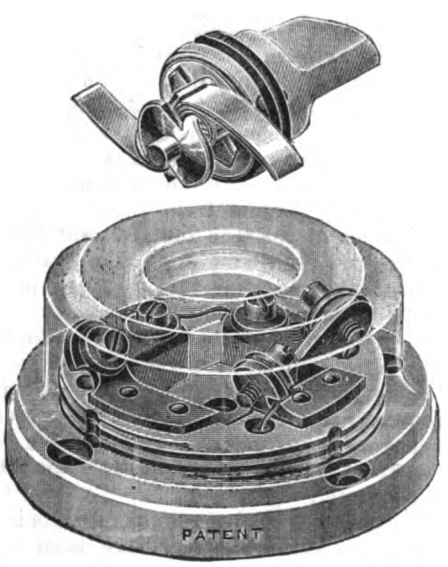

FIG. 1.

special construction, and persons, whether wilfully or ignorantly, turning the key against the springs can do no mischief through buckling them, the key undoing, but not detaching, a rubber ring taking all strain against the roof of the cover. The brasswork of the key is fixed to it by an improved patented method which has superseded the use of tapped porcelain. The brass cradle-piece to which the springs are attached is now made out of stampings only, the start of the spring being clamped between lugs attached to the two parts forming the complete cradle. In

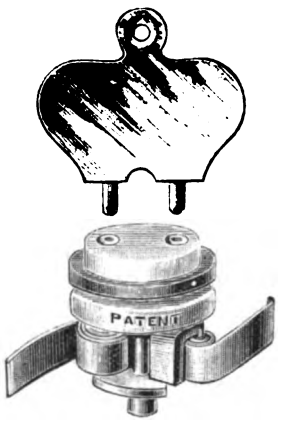

FIG. 2.

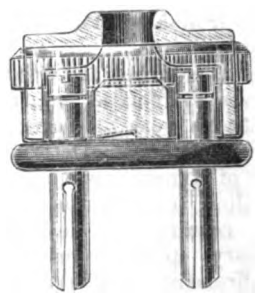

FIG. 3.

this manner the split pins previously used for this purpose are done away with. Improved terminals are also used in all sizes, the method adopted in the smallest size being shown in Fig. 1, the leading wires being drawn into the slot of the lug on the contact plate and clamped under the screw, the slot preventing it slipping out and allowing the wire practically a full turn under the screw. In the

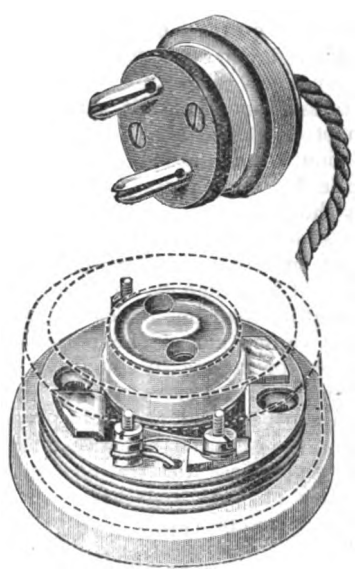

FIG. 4.

larger sizes, use is made of a screw-eye terminal, the leading wires passing through the screw-eye and being clamped against the upright lug of the contact plate, through which the screw-eye passes, by means of a hollow nut. The three-ampere and six-ampere sizes can be fitted, if desired, with porcelain centres for use with removable

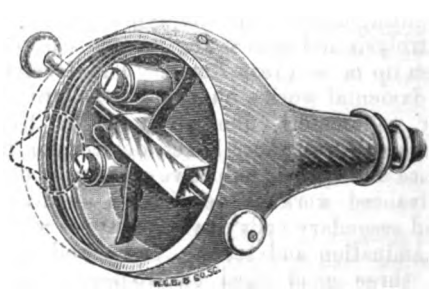

FIG. 5.

keys, which are shown in Fig. 2. A three-ampere damp and dust proof pattern, with brass cover, is now on the market, and is intended for use in exposed positions.

Fig. 3 shows an improved two-pin ratchet plug for use in the Unique combination switch and wall socket (which

Digitized by Google

is represented in Fig. 4), which prevents the springs being damaged if turned backwards, the spring tongue of the ratchet only engaging when turning to the right. The construction and operation of the plug can be readily understood from the illustration.

Fig. 5 shows an improved form of bowspring pear switch.

COMPANIES' MEETINGS.

ELECTRIC CONSTRUCTION COMPANY, LIMITED.

The first annual general meeting of this Company was held at Cannon-street Hotel yesterday afternoon to receive the report of the directors and the accounts, which we printed in our last issue. Sir Daniel Cooper, Bart., G.C.M.G., occupied the chair.

The Chairman, in moving the adoption of the accounts and report, stated that before the shareholders could form a sound opinion on the accounts it was necessary that he should briefly give some idea of the troubles and difficulties the directors had had to deal with and overcome in the past year. They were aware that the old company was successfully reconstructed last year, but besides the work of reconstruction the Board and the managing director had to deal with several entanglements that had to be taken over as a legacy from the old corporation. These matters had been dealt with and, if not completely straightened out, were now in a comparatively narrow compass. At the end of December the heads of three important departments at Bushbury resigned on one month's notice, without any intelligible cause, and would not be induced to stay a short time longer till their places could be conveniently filled by others. At the same time, Mr. Parker, the works director, intimated to the Board that he would not renew his engagement, which was to expire in the coming May. The Board had no desire to retain him as works director, but they were willing to keep up his connection with the Company, and offered him a very liberal retaining fee as consulting engineer. This Mr. Parker declined to accept. About this time rumours became very prevalent that rival works were about to be built at Wolverhampton, but Mr. Parker strenuously denied that he had anything to do with them. Under these circumstances immediate steps had to be taken to reorganise the establishment, and in April it was found expedient to anticipate the termination of Mr. Parker's engagement by dispensing with his services. Now that the staff had been reorganised the Board were not sorry that the changes had been made, because they had secured a chief engineer and a technical staff at Bushbury in whose ability and loyalty they had full confidence; but it would be understood that such extensive changes could not be made without seriously interrupting the work in hand and the continuous flow of new orders, and that these explanations were necessary before a just conclusion could be come to respecting the accounts. He was happy to think that the accounts did not seem to require much explanation. And first, as respects the profit and loss account, he could not say that he was satisfied, although it was quite as good as could be expected under the circumstances already explained. A good deal owing to depression in business, but perhaps more to the reasons to which he had referred, the profits at Bushbury were too small and the general expenses too large. He hoped the directors would be able to show next year an improvement in both respects. The item of profit—£15,764. 10s.—on sales of shares and debentures of other companies, required some explanation. If the shareholders would refer to the balance-sheet they would observe an asset under the head of shares and debentures of other companies—£147,872. 6s. 7d. These interests in other companies were valued by the directors, when taken over from the old company, according to the best of their judgment. They had great difficulty in arriving at what they considered a fair valuation, because none of the securities had market quotations. After much deliberation the prices fixed were such as were considered safe, but at the same time they could not then have been realised in the market. The values depended on the development of the undertakings. As it happened, the interests in certain of these properties matured more quickly than was anticipated, and the directors found an opportunity of realising them before the end of the financial year, with a profit of £15,764. 10s.; this profit, less a proportion for general expenses, it was proposed to apply in reducing the amount at debit of this account, which would thus be strengthened by £12,500 to meet any unfavourable realisations, should such arise. Beyond the account—shares and debentures of other companies—he did not think there was any other item in the balance-sheet requiring explanation. During the past year there had been extreme depression in business generally, and very keen competition in electric manufactures, but, as would be seen from the report and accounts, the Company could fairly say that they had held their own. As to the future, he believed they had at Bushbury the finest electric works in the kingdom, and they were situated in a locality where work could be executed quite as economically as anywhere. Mr. Blackburn, the recently appointed chief engineer at Bushbury, had had wide experience in all kinds of electrical engineering, and was supported by a technical staff and a body of artisans at least equal to any other in the United Kingdom. All were determined to maintain the high character of the work hitherto turned out by the establishment, and the directors believed this could be done with greater economy that heretofore. The future, of course, depended to a large extent on the business activity, not only in this, but in other countries which they supplied with their manufactures. All he could say was that they expected to obtain a fair share of what work was going and to carry it out with reasonable profit to the shareholders. The business was never in so stable a position as it was to-day, and he not think there was any cause to be apprehensive of the future. Before moving the formal resolution, he would add that a moderate increase of capital would be of advantage to the Company. There remained of the £100,000 preference capital £74,010 unissued. The rate of dividend—7 per cent.—they thought too high, considering the improved position in which the Company now stood, but there were various difficulties in the way of reducing the rate. A quotation on the Stock Exchange for the preference shares had been obtained, and, as they could not redeem the portion issued, it would probably be impracticable to obtain another quotation for a new issue at a lower figure. The directors had come to no conclusion on the subject, but it was probable that they might resolve to offer the balance of the present preferred shares to the shareholders, giving ample time to pay up the calls, and thus the existing shareholders would receive, as they were well entitled to, the benefit of the high dividend payable on these preference shares.

Mr. Emile Garcke, in seconding the motion, said he would only add an expression of confidence in the staff. The success of such a company depended largely on the loyalty and capacity of the staff and of the body of artisans, and the directors had every desire to enlist the confidence of their workmen.

Mr. Williams considered that the expenses were unduly heavy, and wanted to know how Mr. Parker's secession would affect the Company.

Mr. Cook said that there was plenty of capital in the concern, but it was mainly lost. They had only £8,753 cash in hand, and about £32,000 due from debtors.

Mr. Hancock stated that affairs were very dispiriting. Patents were running out, and yet only £3,000 were allowed for depreciation, or only 1 per cent. That should be increased, or else someday there would be a dead loss. When the shareholders came in they were induced to do so by the stress which had been laid on the talents and connection of Mr. Parker, and his departure was a great loss to the Company. During the last four years about £500,000 had virtually been lost. Much of that loss had been due to the two sources from which the directors had been drawn—the Balfour set and the Irving Courtenay set. Some directors should be drawn from outside sources.

Sir D. Cooper stated that the present directorate were not responsible for the doings of their predecessors.

Mr. E. Garcke, on behalf of the directors, explained that the meeting must remember that the Board had only had one year's trial. With respect to Mr. Parker, he was building works at Wolverhampton. As regarded depreciation, the directors thought that if they kept the works in their present condition, and put in new tools, the sum provided was sufficient. He thought that as regarded Mr. Parker they had made a satisfactory change. He hoped that they would be able to show better results, and as good as any going.

The motion having been carried, Sir D. Cooper was re-elected a director, and Messrs. James Meston and Co. were reappointed auditors.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Portsmouth.—The Corporation want tenders by the 22nd inst. for the purchase of second-hand electrical plant.

Edinburgh.—The last date for the delivery of tenders for the arc lamp-posts required by the Corporation is the 17th inst.

Cheltenham.—The Town Council want a seven-ton hand-power overhead crane for their electric lighting station. Particulars are obtainable from the borough surveyor. Tenders are to be sent in by the 18th inst.

Bristol.—Tenders are invited for the construction of transformer chambers in certain streets in Clifton, for the Electrical Committee. Specification and plan of the arrangements required may be inspected on application to Mr. H. Faraday Proctor, M.I.E.E., city electrical engineer, Temple-back. Tenders must be delivered by noon on 18th inst., addressed to the Electrical Committee, Temple-back, Bristol, and endorsed "Tender for Transformer Chambers."

South Shields.—The following tenders are invited for the supply and erection of the following plant, for the Corporation: Section A—boiler-house plant, including boilers (marine type), fittings, pipes, chimneys, etc. Section B—pump-house plant, including double-acting, slow-speed, circulating and feed pumps, cast-iron tank, pipes, and fittings in connection therewith. Section C—engine-house and sub-station plant, including 100 and 25 kilowatt steam alternators, with double or triple compound engines, steam exciter, circulating pipes, switchboard and instruments, sub-stations, and transformers. Section D—underground work, including rubber-covered cables, cast-iron pipes, boxes, switches, and trenching. Section E—arc lamps, lamp-posts, switches, and transformers. Section F—meters. Firms tendering are at liberty to tender for any section or sections, or for the whole of the sections, but not for part of a section. Copies of specification, including plans, conditions of tender, and contract, can be obtained at the Borough Electrical Engineer's Office, South Shields, on and after 17th inst., on payment of £3. 3s., which sum will be returned on receipt of a *bond*

Digitized by Google

fide tender. Tenders, sealed and marked "Tender for Electric Lighting," to be delivered to Mr. J. Moore Hayton, town clerk, Court Buildings, South Shields, by October 31.

RESULTS OF TENDERS.

Wolverhampton.—The School Board have accepted the tender of Messrs. T. W. Scott and Co., electrical engineers, etc., of Birmingham, amounting to £233. 10s., for an installation of the electric light at the Walsall-street new school, in accordance with the plans and specifications prepared by the architect of the Board.

BUSINESS NOTES.

Bacup.—The Liberal Club is to be lighted electrically.

Eastbourne—The electric light company are extending their mains.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,887.

Blackburn.—Provisional arrangements have been made for lighting the free library by electricity.

Commercial Cable Company.—A quarterly dividend of 1¾ per cent. has been declared, payable on October 1.

The Temple.—Preparations are being made for the installation of the electric light in the Middle Temple Library and Hall.

Direct Spanish Telegraph Company.—The Board recommends a dividend of 1s. 8d per share for the half-year ended June 30.

Ayr.—The Secretary for Scotland approves of the Ayr Town Council borrowing £15,000 for the installation of the electric light.

Southampton.—The Town Council are to hold a special meeting to consider the suggested purchase of the electric light undertaking.

Hove.—The new baths and laundry were opened on Wednesday. The buildings are lighted throughout by electricity, generated on the premises.

National and International Exhibitions, Limited.—This Company has been registered to promote, or assist in promoting, exhibitions, etc.

Llandudno.—The grounds of Rivière's concert hall have been lighted by Mr. Kingsland with arc lamps. Motor power is supplied by a gas-engine.

Liverpool.—The Duke of York on Monday laid a foundation-stone of new post office buildings at Liverpool. They are to be lighted by electricity.

Dover.—Notice of intention to lay electric light mains in Stroud-street and Wood-street has been received by the Town Council from the Dover Company.

Fareham.—Major Cardew, R.E., has held an enquiry in connection with the proposed transfer to the Local Board of the electric light undertaking.

Bristol.—A case of nuisance at the electric lighting works, owing to a smoky chimney, has been reported to the Sanitary Committee of the Town Council.

Manchester.—The lighting of Mudie's Library, Manchester, has been placed with Messrs. Drake and Gorham, of London, and the number of lights will equal about 100 of 8 c.p.

Queensbury.—Plans have been passed by the Local Board for a channel on the road to carry the electric supply conductor for Prospect House, for Messrs. J. Foster and Son.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending 9th inst. amounted to £1,054, as compared with £724 in the corresponding week of last year.

Reading.—An arcade of 20 shops has been opened in Friar-street, Reading. Sixteen of them are furnished with the electric light. The central part of the arcade is lighted by six electroliers, which give a brilliant illumination.

Hampstead General Electric Fitting Company, Limited.—This Company has been registered, with a capital of £1,000 in £1 shares, to carry on business as electrical and general engineers, iron and brass founders, wire-drawers, etc.

Streatham.—The Greyhound Inn has been lighted electrically, the work having been carried out by Mr. George Stegman, Clapham Junction. The installation comprises 80 16-c.p. lamps, and power is obtained from a Stockport gas-engine.

Taunton.—The Electric Light Committee of the Town Council have presented an estimate for further extension, amounting to £5,000, and they recommend that application be made to the Local Government Board for their sanction to borrow that sum.

Southport.—The Electricity Works and Plant Sub-Committee of the Town Council have recommended that a low-tension main be laid down on the Promenade, from Bold-street to Seabank-road, along Seabank-road, and in Lord-street from Seabank-road to Bold-street.

London.—Messrs. Drake and Gorham have obtained the contract for the lighting of the Royal Geographical Society's building by means of about 120 lights. The current is to be supplied from the central station, and it has been decided to do away with the gas altogether and to rely on the electric light alone.

City and South London Railway.—The receipts of the Company for the week ended September 9 were £840, against £754 for the corresponding week of 1893, or an increase of £86. The total receipts for the current period of the present half-year amount to £8,576, as against £8,148 in the corresponding period of 1893.

Northampton.—The annual report of the Northampton borough surveyor has been printed. It is incidentally stated that a considerable amount of work has been caused by the electric light company disturbing the footways in laying their mains, and a large amount of supervision has been necessary in consequence.

Stafford.—The work at the central station of the Town Council is going on satisfactorily, and the foundations are now put in. Six tenders have been received for the supply of cables, and have been submitted to the consulting engineer, Dr. Hopkinson, for him to report upon. It is intended to lay the memorial stone on October 17.

Middlesbrough.—The deputation appointed by the Middlesbrough Electric Lighting Committee to make enquiries relative to electric lighting in towns, have arrived at the conclusion that it would be in the interests of the borough to proceed forthwith with the laying down of an electric installation at a cost not exceeding £25,000.

Nelson.—The minutes of the Gas Committee of the Town Council state that the charges for electric light supply and the rent of meters had been reduced, and that the committee had resolved that all electric power for motor purposes be supplied to consumers at 4d. per unit, and the ordinary discount, and that the borough accountant arrange accordingly.

Gateshead.—The Town Improvement Committee have reported to the Town Council that their sub-committee to whom they had delegated the question of the advisability or otherwise of introducing a system of electric lighting into the borough, had before them a report from the town surveyor on the subject, and that they would report thereon at a future meeting.

Wells.—The Town Council is about to seriously consider the subject of adopting electricity for the public lighting of the city. The majority are decidedly favourable to it if it can be done at a reasonable cost. In the meantime Mr. Councillor Sheldon is laying down machinery and dynamos with a view to lighting his engineering works and his residence with electricity.

Halifax—The laying of the street cable has been completed, and the work of connecting with the business and other premises to be supplied is now in progress. At the works the stone beds for the engines, which Messrs. Pollit and Wigzell, of Sowerby Bridge, have now got ready for removal, are being prepared with every despatch. Fresh applications for the electric light continue to be received.

Devonport.—Intimations received by the Town Council from the County of London and Brush Provincial Electric Lighting Company, Limited, and the Great Western Electric Light and Power Company, Limited, of their intention to apply to the Board of Trade for provisional orders to supply electricity within the district of the Urban Sanitary Authority of Devonport, have been referred to the Streets Committee.

Luton.—Mr. Wilkinson, a member of the Town Council, has given notice that he will move the following resolution: "That the Highways and Lighting or a specially appointed committee do consider and bring up a report upon the question of applying for and ultimately obtaining a provisional order for the supply of electricity for public and private purposes within the borough of Luton, and that the Highways Committee do consider and report upon the probable cost of obtaining such order."

Sunderland.—Another official report has been prepared on the proposal to light the Town Hall by electricity. It is estimated that 312 lamps and sockets will be required inside the building, the cost of which is put at £450. An extra £70 would be required to adapt the Fawcett-street front, the plant and necessary alterations costing altogether about £600. The average cost of lighting by gas and maintenance, for three years past, has been £88 per annum, whereas electricity would cost £136 per annum.

Folkestone.—The following appear on the agenda of the Town Council: "To consider the question of the scheme for lighting the borough by electricity, proposed by Mr. Daniel Baker, at a cost of £12,000, and matters incidental thereto, and to make orders and to pass resolutions with reference thereto," and "to reconsider the subject of the report of the Special Committee as to electric lighting, which has been received by the Corporation, and the scheme and matters connected with that report and incident thereto, and to make orders and to pass resolutions with reference thereto."

Cheltenham.—The Town Council have received a certificate from the borough surveyor to the effect that Messrs. Malvern and Sons, the contractors, were entitled to £400 on account of the work done at the electric lighting station, and the same was passed. The town clerk read a correspondence between the Brush Electrical Engineering Company and himself upon the subject of the contract for transformers, and the town clerk's letters were approved and he was directed to forward them the draft contract for approval. The regulations relating to the supply of electric energy were approved.

Hastings.—The Public Lighting Committee of the Town Council have had their attention called to the dark state of that part of East-parade, etc., in the vicinity of the lifeboat-house after one-half of the electric lamps had been turned out at midnight, and in order to obviate this defect they had caused instructions to be given to the electric lighting company, by virtue of the terms of the contract with the company, to keep the lamp to the west of the Cutter Hotel (which was one of those turned out at midnight) alight all night in future, which would make the number of lamps to be lighted all night one in excess of half the total number of the lamps, and they recommended that their action in the matter be confirmed. This was carried.

Digitized by Google

Hertford.—A public meeting of the ratepayers has been held for the purpose of considering the electric lighting scheme now before the Town Council. The chair was occupied by Mr. A. Hawks, and Mr. G. A. Munnings, a gas shareholder moved, "That this meeting having considered the proposed electric lighting scheme of the Town Council is of opinion that it is not desirable for the Council to proceed with it." This motion having been seconded, Mr. G. R. Durrant moved as an amendment, "That this meeting of burgesses desires to express its confidence in its elected representatives in the Town Council, and leaves the question of the introduction of electric light into Hertford to their discretion," which was seconded. On a show of hands the resolution was carried.

Bath.—The Bath Electric Light Company are using at their works in Dorchester-street a mixture of tar and creosote for firing the boilers. It is ejected by steam pressure in two small jets from a reservoir, itself heated also by steam, on to the furnace fire. The amount of coal or coke required is reduced to a minimum. It is stated that the experiments, which have resulted in the present application of the system, have been several months in progress under the supervision of Mr. G. F. Metzger, the engineer and manager, and involved much trouble to overcome. At the station powerful new engines and dynamos, making with those already in use 11 in number (the former being of some 900 h p. in the aggregate) are being erected, as well as a new switchboard.

Bradford.—The gas and electricity accounts were presented to the Bradford Town Council on Tuesday. Alderman W. Moulson, chairman of the Gas and Electricity Supply Committee, moved the adoption of the minutes of that body, and said that with regard to the electricity supply he had a favourable report to make. The laying of the three-wire system had involved an extra expenditure of about £700 on account of salaries and wages, but notwithstanding this there was a net profit on the past half-year of £336, as compared with £625 in the corresponding half of 1893. The £700 comes out of revenue. The total expenses of the electricity department were £3,221. 7s. 5d., and the gross income £5,418. 7s. 10d., as compared with £4,543. 8s. 3d. for the corresponding period of last year. The gross profit was £2,293. 15s. 1d., as against £2,189.

Yarmouth.—The borough surveyor has asked for instructions as to the gas lamps to be turned out when the permanent plant should be ready for work. He stated that along the line of the electric lamps there were about 120 gas lamps which would not be required, and he recommended that a joint committee of the Electric Light Committee and of the Lamp Committee should consider this question, as also that of the number of hours during which the arc lamps should be kept lighted. The committee recommended the Council to instruct the town clerk to give the gas company notice that about 120 lamps would not be required after November 1 next, the borough surveyor to prepare a list of the lamps which would not be required, and that the joint committee inspect the districts affected as soon as the borough surveyor had effected the alteration. The report was adopted.

Yeadon.—The Local Board on Monday night discussed the electric lighting question. The Board have obtained a provisional order giving them power to manufacture and supply electricity for public and private lighting purposes, and have obtained from several firms tenders as to the sum at which the plant could be put down; but the lowest of these is somewhat higher than the estimate which was submitted to the ratepayers' meeting that sanctioned the Board going on with the scheme. Some of the members of the Board are now in favour of deferring the question until after the election in November next, whilst others argue that as a mandate was received from the ratepayers to go on with the scheme, the Board are in duty bound to do so. Ultimately, after considerable discussion, the meeting decided to call in an electrical expert to advise the Board on the tenders and samples of materials sent in.

Dundee.—Messrs. William Ramsay and Co., electrical engineers, 254, Argyle-street, Glasgow, have secured an important contract from ex-Bailie Taylor for the illumination by electricity of his business premises in Yeaman's Shore and his steamer "Alice Taylor." By means of a private dynamo, and utilising the power of a steam-engine at present embraced in his stock, Mr. Taylor is to light all his offices, stores, stables, and workshops. Four powerful arc lamps, each of 2,000 c.p., are to be provided for the yards, two of these being placed in the railway yard and the other two in his English coal yard. An interesting fact is that the electric light will be introduced into Mr. Taylor's foreman's house, this being probably the first workman's house in the city thus treated. In resolving to have the "Alice Taylor" electrically lighted a new departure will be made in the coal trade, this being the first local steamer thus exclusively employed to be lighted in this manner.

Grange.—The following letter has been read at a meeting of the Local Board from Mr. C. W. Dean, clerk to the Rural Sanitary Authority: "The R.S.A. have received formal notice of the intention of the Windermere and District Electricity Supply Company, Limited, to make application to the Board of Trade for an order authorising the company to supply electrical energy within the area of the jurisdiction of the Authority, and the matter has been referred to a committee for consideration and report. I am instructed by the committee to enquire if your Authority has had the matter under their consideration, and what action (if any) has been determined upon. I am also directed to enquire if your Authority would be willing to appoint a small committee to join with this and other local authorities in the district in conference, with the view to combined opposition to the application in question." It was agreed that the clerk and Messrs. Midgley, Booth, and Westwood be appointed to confer with the committee of the Rural Sanitary Authority.

Private Telephony.—The new building in Salisbury-square, E.C., recently erected for Messrs. Lloyd, Limited, has been fitted throughout with telephones, on the intercommunication system, by the Private Wire and Telephone Installation Company, of 110, Cannon-street. The instruments, which are all of the magneto pattern, have been specially made in light oak to match the wainscoting and furniture of the rooms, and are eight in number—five of them desk sets and three wall sets. By this system all parts are enabled to have instant and direct communication with each other, which is not only more expeditious, but saves the services of an attendant, which would be necessary on the central exchange system. It is claimed that one of the advantages of the system as installed here is that when conversation is ended it is only necessary to withdraw the plug, it not being necessary to insert it in a "home" socket. All the instruments are fitted with Hunnings's transmitters, and the whole installation is worked by dry batteries, as also are the electric bells which have been fitted throughout the building by the same company.

Sheffield.—The proprietors of the *Sheffield Telegraph* are at present putting in the foundations of a new electric light plant, consisting of an engine and dynamo, which will form a duplicate to the existing plant now in use at the office for lighting and electric motive power. At present the electric lighting plant consists of a small dynamo by Messrs. Scott, Mountain, and Co., of Newcastle, capable of supplying 100 16-c.p. lights. This is used during the daytime. When the light is needed in quantity the larger plant is switched on, consisting of one of Messrs. Marshall's 45-i.h.p. high-speed engines, coupled by belt to a Wilson Hartnell 500-light dynamo. The new installation, which will be a duplicate of the above large plant, will consist of a Willans compound high-speed engine running at 500 revolutions per minute, and coupled direct to a Wilson Hartnell dynamo capable of supplying 500 16-c.p. lamps The Free Libraries and Museum Committee think it desirable to postpone the proposed cleaning, painting, and decoration of the Weston Museum until next spring, in view of the introduction of the electric light into the building in the meantime. Information and detailed particulars of electric lighting are to be obtained.

Newport (Mon.).—The Electric Lighting Sub-Committee of the Town Council have reported that the Corporation would be in a position to supply electricity in the month of October. The engine plant, which was being made by the Uskside Company, had been inspected by the engineer, and was progressing satisfactorily. The committee had also themselves inspected the electric lighting station and the progress of the buildings. The Uskside Company wrote asking for a payment on account, but the committee recommended that the terms of the contract be adhered to as to payment on delivery. None of the engine plant had as yet been delivered. Mr. Clifford Phillips asked whether the attention of the Traffic and Lighting Committee had been drawn to the bad lighting of Church-road Alderman Bear enquired whether, in view of the electric lighting of the borough, it was intended to continue to erect lamps. Mr. Brown (chairman of the Lighting and Traffic Committee) said that the spots where the electric lights were to be erected had been already fixed. No complaint had been made about the lighting of Church-road, and therefore the matter had not been taken into consideration. The Works Committee have reported in favour of erecting a refuge with an arc lamp at the cross-roads at the head of Newport Bridge.

Burton.—George-street Chapel has been renovated, and the electric light installed throughout. At a meeting of the Town Council, Councillor Rugg asked the chairman of the committee (Alderman Lowe) whether it was a fact that there was an enormous waste of electricity going on at the works when the electric lighting engines were running of an evening, and whether it was necessary to buy accumulators to enable them to store such wasted electricity so that it might be used in some of the public streets, and for electrical fans for ventilating public buildings. Alderman Lowe said perhaps Mr. Ramsden would be better able to reply to the electric light question than he (Alderman Lowe) was. But as he understood it, the system of electric lighting adopted in Burton was not one in which the storage arrangements could be adopted. The storage system could be carried out if there was only a small area to be dealt with, but over a scattered area like that at Burton it was not only unnecessary, but would be very expensive That, at least, was Mr. Ramsden's opinion. Councillor Rugg: You don't answer the question with regard to the waste of electricity. Mr. Ramsden (gas and electrical engineer): There is no waste. Alderman Lowe: That is a complete answer. Are you satisfied? Councillor Rugg: I will bring the matter forward again.

Cardiff.—The preparations connected with the lighting of Cardiff by electricity are now nearly completed. All the machinery and boilers are in position, the steam and exhaust pipes are being fixed, and final tests will shortly be run on the lamps, etc., to ascertain that everything is in a proper condition for starting. Fires have also been for some time in the boilers to make sure that everything is dry, and to prevent any possibility of cracking. Everything in the town is complete. The gas lamps are to be replaced by electric lamps. The Corporation insist that the new light shall immediately follow upon the old, so that the streets may not for a single night be improperly lighted. This will necessitate certain extra work and occasion some delay, though very little according to present arrangements. The prices for consumers have been fixed by the Cardiff Corporation at 6d. per Board of Trade unit for the

Digitized by Google

current for lighting purposes, and 4d. per unit for supplying motive power for machinery. At Monday's meeting of the Town Council an intimation was made by Alderman Carey that the electric light would be started by the end of this month, or at the beginning of October. This he made, he said, on the authority of Mr. Massey, consulting electrical engineer to the Corporation. Tradesmen who intended taking advantage of the light were asked to take immediate steps for getting it laid on, inasmuch as the wiring would occupy some time. There would be a preliminary trial of the light, after which the new illuminant would be formally inaugurated.

Brighton.—The Theatre Royal has been reopened after renovation, and has been lighted electrically. The installation has been carried out by Messrs. F. Geere Howard and E S. Dashwood, of 10, Berners-street, London, W., under the personal superintendence of Mr. Dashwood. The installation comprises about 600 16-c.p. incandescent lamps, and extends from the stage to the colonnade in the front, which is illuminated by a series of incandescent lamps. It includes the entrance halls, the lobbies, corridors, staircases, and every part of the auditorium from the gallery to the stalls; and it is manifest that this has an exceedingly beneficial effect upon the ventilation of the building. About 400 of the lamps are on the stage. The battens, bearing variously-coloured lamps, are patent fireproof split steel tubes, and these, with the footlights and other portions of the installation, are controlled by a switchboard on the prompt side of the stage, the switches being so arranged as to permit of the lighting being dealt with in sections or as a whole. There are also separate switches in the front of the house which may be used independently of the main switches; and, as a precaution against any failure in the lighting arrangements, gas is laid on all over the house in such a manner that the whole may be controlled from two or three taps The electric lighting installation is on the three-wire system, and the current is obtained from the Corporation mains. The Town Council have decided to raise the salary of Mr. W. H. Everett, meter superintendent at the electric generating station.

Londonderry.—At a quarterly meeting of the Corporation a report has been submitted from the resident electrical engineer (Mr. Christie) to the effect that between August 22 and September 4 seven failures took place, placing about one-fourth of the portion of the city lighted by electricity in darkness for a night on each occasion. Six of the failures were due to bursts in the cable at different parts of the circuits. In the seventh case the failure, which extinguished 22 lamps, was caused by a faulty contact in one of the lamps. The failures, Mr. Christie added were not at all attributable to any action of himself or his staff. Councillor Hastings, chairman of the Lighting Committee, said he had asked for a full statement of the facts from Mr. Christie. They had been kept in the dark too long. A letter was read from Messrs. Siemens Bros. declining to admit that the repeated failures in the cables were due to defective manufacture or to careless handling on the part of their men. As, however, they were greatly interested in the success of the installation, they would consider the question of defraying the expense to which the Corporation had been put in reopening and closing the streets to reach the defective parts of the cables. A question was asked regarding any suggestions for preventing these failures in the future, but Councillor Hastings said such questions could not be answered. Messrs. Siemens Bros. were responsible for the working until May 29, 1895, when their period of maintenance would terminate. It transpired that Mr. Blake, the electrical engineer, under whom the installation was introduced, had gone to London to consult Dr. John Hopkinson, the consulting electrical engineer, who had already passed the specifications. The consultation took place with reference to the failures in the cable. Dr. Hopkinson's opinion had not yet arrived. A letter had come from him which, however, the chairman declined to make public at present.

Portsmouth.—The Electric Light Committee of the Town Council have reported that it would be necessary to enlarge the generating plant at a further cost of £6,000, and recommended that the Local Government Board should be requested to sanction the borrowing of £20,000 to cover any further extension that might be required, so as to obviate the necessity of making repeated applications. Alderman Ellis, in moving the adoption of the report, said that at the present time they were supplying 4,140 16-c.p. lamps and 725 were waiting to be wired, making a total of 4,865, which meant an income of nearly £5,000 a year. To that they must add the increase for Corporation street-lighting. Assuming that the inhabitants went on applying for the light to the same extent as heretofore, the Corporation would have an income from that source of from £12,000 to £14,000. Mr. Kimber seconded. Alderman Sir W. Pink said that he feared they were going too fast. He should like to know what the real income up to the present time had been, and what the real prospects of the light were. Mr. Evans also opposed the recommendation of the committee, saying that he thought £6,000 enough for one time. They had no right to invest so large a sum unless they could see a fair return for it. He moved that the £6,000 only be granted. Sir W. Pink seconded the amendment. Alderman Scott Foster said that it seemed to him to be a great mistake to refuse the money necessary for the extensions which were rendered necessary by the demands of the public. After further discussion the resolution was passed by a large majority. The President of the Chamber of Commerce has pointed out at a meeting of that body that after the electric light had been turned on there was such a buzzing in the telephone instruments that it was impossible to communicate a message. The Secretary said he had written to the company and had received a reply that they were dealing with the matter.

Ulverston.—The clerk to the Local Board has read the minutes of a committee meeting at which the following resolution was passed: "That the clerk write to the Board of Trade stating that having considered the report of the deputation which waited upon the Board of Trade, and fully considered the question of electric lighting of the town, and ascertained that at the present time the inhabitants within the restricted area of supply would not take the light in the place of gas, this Board are of opinion that looking to the great expense they have had to incur in making provision for an efficient supply of gas, they should not be called upon to lay down an electric light plant until the owners and ratepayers within the Board's district signify their desire that such should be afforded, but as soon as such desire is expressed the Board will be prepared to meet the same, and the Board trust that this decision may be satisfactory to the Board of Trade, and that the Board of Trade will not entertain any application by outside parties to supply electricity within the Board's district." The Gas and Water Committee received a letter from the clerk to the Ulverston Rural Sanitary Authority, asking if the Local Board would appoint a committee to meet a committee appointed by the Authority to consider the question of opposing the provisional order of which the Windermere District Electricity Supply Company have given notice to the Board and other authorities within North Lonsdale. It was recommended that the Board should appoint a committee. Mr. Tosh moved, and Mr. Case seconded, the adoption of the report. Mr. Birkett asked whether the appointment of the committee proposed would involve any expense, and whether it was not in contradiction of the letter sent to the Board of Trade. The Clerk said it was really intended to strengthen the opposition, and the committee would have to report to the Board before any expense was incurred. Mr. Tosh said the object was that the various authorities should co-operate to oppose the proposed invasion of this district by an outside company. The report was approved, and it was resolved that the committee consist of the chairman of the Board and the chairman of each standing committee.

Bury.—A long discussion has taken place at a meeting of the Town Council as to the letting of the contract for the installation of electric lighting. The tender of Messrs. Storrs and Sons, Stalybridge, had been accepted after revised tenders had been sent by that firm and Messrs. Thompson and Brierley, of Bury. Mr. Spencer said that the tender accepted was only about £70 to £80 less than that of a local firm, amounting to only about 1 per cent. more, and he contended that Messrs. Thompson and Brierley ought to have the contract, as the money would be spent in the town, and would thus circulate to the benefit of all. Dr. Greenhalgh seconded an amendment to this effect. The Mayor said everything had been done that could be done to give a local firm the preference, and the real difference in the tenders was about £160. Messrs. Storrs would have to pay the same wages, and perhaps employ a number of local men. Besides, if the local tender was accepted the difference would not go to the ratepayers, but to the local firm. Mr. W. Sykes said he looked upon the question as one of principle. If Mr. Spencer wanted an article, and a Heywood firm would supply it for £99 and a Bury firm would not supply it at less than £101, he would employ the Heywood firm. And what he would do privately he ought to do on the Council—spend the ratepayers' money to the best advantage. Members of that Council such as Mr. Bryon did work in other towns; and if Bury set up to be a close Corporation, and employed only local firms, they would want a wall built round. He found that every shop in Bury sold foreign goods such as he manufactured, but he did not go whining about and saying that they should buy of his firm. Mr. Collinge said that Messrs. Thompson and Brierley were heavy ratepayers, and the difference was so small that it would pay to give them the contract. Mr. Bryon said he had been employed by the Manchester Corporation for four or five years, and had at present a heavy contract with them. If only local tenders were to be accepted outside firms would cease to tender, and the work now done from outside districts would not be given to him and others. Alderman Brierley had a large contract on at Prestwich, and Prestwich and Manchester might object if such a rule as that suggested were to obtain. The amendment was defeated by 15 to 10.

Birmingham.—The installation of the electric light at the Market Hall is nearly complete, and the new illuminating appliances will be brought into use in about a fortnight. At present the hall is lighted by a central ring of gas-jets and by standards and naked burners connected with the various stalls. Altogether there are 550 burners to illuminate a building 350ft. long and 100ft. wide. Enquiries and experiments were made by the Markets Committee as to an improved method of gas lighting, and it was found that electric arc lights would be more economical. The new installation consists of 33 arc lights, some of which are outside the building. The electric energy will be taken from the electric supply company's mains in Bell-street. The light from the arc lamps will be between three and four times that derived from the present gas lighting, even after allowing for the loss of half the total light on account of the use of opaline globes. The cost of running the electric lamps will be £507 for energy and £25 for carbons, as compared with £522 for gas. It is proposed, however, to pay off the capital outlay of £900 in 10 years, making an addition for interest and sinking fund of £100 per annum for the period named. The Markets Committee considered the desirability of establishing their own generating plant This would have still further reduced the annual cost, but it was thought the difference was not worth the inconvenience of introducing new machinery. The new installation has been designed by Messrs. Henry Lea and Thornbery, civil engineers, of Birmingham, under

Digitized by Google

whom it is being carried out by the Walsall Electrical Company as contractors. Messrs. Lea and Thornbery also have in hand the introduction of electric lighting for the new meat market, the municipal school, and the botanical gardens. The arc lamps are of the Brockie-Pell pattern, and the ornamental ironwork is by Messrs. Hart, Son, and Peard.

Whitehaven.—The chairman of the trustees for the town and harbour of Whitehaven, Mr. J. G. Dees, in proposing the confirmation of the minutes of the Electric Lighting Committee, stated that they had a deputation from the Eccles Corporation, who are considering the advisability of adopting electricity as a means of public and private lighting. They expressed themselves highly gratified with the light and with the manner in which they had been entertained. Applications for the electric light at Whitehaven continued to come in in almost too satisfactory a manner. They had now applications nearly up to their present requirements, and there were several more applications coming in. With regard to the application to the Local Government Board for power to borrow £5,000 more on electric lighting account, they had expected that the result of the former enquiry and the evidence then given would have been sufficient for the Local Government Board's purposes, but a letter had been received pointing out that it would be necessary to hold another enquiry, also that it would be necessary to apply to borrow £6,304. He moved that application be made to the Local Government Board to borrow this amount, and the motion was agreed to. Mr. Cant asked that some statement should be prepared showing the financial aspect of electricity in connection with the town before they spent a large sum of money upon it. When the subject was first brought up, Mr. Brodie, then engineer, submitted a creeping scheme, then they had a walking scheme, and now it appeared to him they were going in for a flying scheme. The chairman pointed out that he had recently shown that up to March 25 there had been a saving to the ratepayers on the electric lighting as against gas. They had only had the electric light from September 2 to March 25 on which to base their calculations, but even in that period, when the expenditure was extraordinarily heavy, the result of the working was a saving as against the price of gas in the previous year, and the estimate of the surveyor and the Electric Lighting Committee was that there should be a very considerable saving this year. There would be no difficulty in furnishing a statement showing the result of the working of the electric light up to the present time, and he promised that such a statement would be supplied.

Salisbury.—At a meeting of the New Sarum Town Council a letter has been received from Mr. Hammond to the Council stating that he had sent a copy of the following letter to the Board of Trade: "To the Assistant-Secretary, Board of Trade, Whitehall, S.W. Sir,—In reference to the license applied for under the Electric Lighting Acts, 1882 and 1888, by the Salisbury Electric Light and Supply Company, Limited, in respect of the city of Salisbury, in the county of Wilts, I beg to hand you, on behalf of the Corporation of Salisbury, acting as the local authority, a draft of the said license, with some slight alterations and additions thereto, and beg to express the desire of the Corporation that the amendments indicated shall be made by the Board of Trade in granting the license. I beg to make the following observations thereon: Section 3—The date filled in is deemed to be the most suitable one from which the license shall date. Section 4—The additional clause becomes necessary in the event of the possibility of the local authority becoming the purchasers of the undertaking. New Section 8—The local authority consider that the audit of the accounts which is usually provided for in the provisional orders shall not apply in the case of this license. Section 23—It is felt that the local authority should have power to make representations and objections. Section 31—The addition is rendered necessary by the possibility of the local authority becoming the purchasers. Section 65—The local authority feel that in the event of revocation, the power of purchase, which usually is inserted in provisional orders, should also apply in the case of a license. Sections 66, 67, 68—The same remarks apply. Section 70—As this section replaces the ordinary penalty sections, it is desired to make it as full as possible, and not to limit the duties by the words 'in relation to the supply of energy.' Fourth schedule—The local authority desire that 8d. should be the maximum price permitted." In the second letter from Mr. Hammond he said, "I believe I am right in saying that Sir Thomas Blomefield has explained to the company the disinclination of the Board of Trade to issue any licenses, and that in view of the application of a provisional order the period would be limited to two years, and that they were contented to accept the license on this basis." Mr. Watson: Then we get for our £50 absolutely nothing. Mr. Nodder: That is just what I anticipated. Mr. Watson: So did I. Mr. Nodder: We have the reputation of being a rich Corporation. Mr. Waters: We came to a wise decision.

Colliery Plant.—In the course of a recent visit of the Federated Association of Colliery Managers to the Forest of Dean, a visit was paid to the Trafalgar Colliery, the directors of which have for some time felt that it was necessary, on account of the increasing distance from the shaft at which the workings were being carried on, to place a good system of haulage in operation, and guided by the previous successful applications of electric power, and on the advice of Mr. F. Brain, it was decided to instal a "main and tail rope" system, operated from the bank at top by electricity. Specifications having been prepared by the consulting engineer to the company, Mr. Le Neve Foster, of London, tenders were invited, and eventually a contract signed with Messrs. Easton, Anderson, and Goolden, Limited, for the supply of the whole plant, comprising a double-cylinder horizontal engine, driving the generating dynamos by means of rope gearing. The engine (which has been built by the firm of Messrs. T. and R. Lees, Hollingwood, Manchester), as at present arranged, is intended to develop 150 h.p. at 85 revolutions when driven by steam at 50lb. pressure, but is specified to develop 264 h.p. at the same speed when driven at 80lb. pressure, which it is intended eventually to adopt. For this reason only one dynamo (if the exciter is omitted from consideration) is at present installed, but the driving ropes are sufficient, and couplings are provided for a second dynamo of equal power to be eventually added. In addition to this a smaller dynamo is in operation, used for exciting the magnets of the generating dynamo and driving some lamps, and capable also of supplying current for the electric pumps already installed. The large generating dynamo has an output of 600 volts and 150 amperes, at 500 revolutions. From the dynamo the current is led to the switchboard, of which all parts carrying the high-tension currents are so enclosed as to be inaccessible while the current is "on," so that accidental shocks are impossible, and then down the shaft by cable insulated with vulcanised indiarubber, being carried in iron pipes, with junction or test boxes at intervals. At the bottom of the shaft the cables are carried on insulators till the haulage engine is reached. This consists of a pair of 5ft. drums, each 3ft. wide, carried loose on the main shaft, to which are keyed friction clutches, enabling either drum alternatively to be driven, the other running free. The present arrangement of the plant has been laid out by Mr. Ll. B. Atkinson, of Messrs. Easton, Anderson, and Goolden, Limited, under the superintendence of Mr. F. Brain and Mr. Le Neve Foster.

Southport.—The Electricity Works and Plant Sub-Committee have recommended the Town Council that a low-tension main be laid down on the promenade from Bold-street to Seabank-road, along Seabank-road, and in Lord-street from Seabank-road to Bold-street. Alderman Hacking, in moving the adoption of the minutes on Wednesday last, said no doubt the members would want to know what they were going to do with respect to the electricity arrangements. They would see from the minutes the committee had decided to lay down a low-tension main on the promenade from Bold-street to Seabank-road, along Seabank-road, and in Lord-street from Seabank-road to Bold-street. They had had an application for electrical energy from the Queen's Hotel, and they thought it possible that they might also have a similar application from the Convalescent Hospital. The reason they decided to do this work at the present time was that they had some hundreds of yards cable over and above what they required for the streets which had been scheduled; they thought that was the proper time to do the work, and that the cables would be more likely to do good when laid than lying in coils in the yard. The building at Crowlands was roofed in, and the stone beds for five of the engines and dynamos were fixed, and they were assured that the others would be completed that week. Councillor Hesford seconded the motion. Councillor Boocock said he had been asked several times when they were to have the electric light. They were told they were within measurable distance of the completion of the work, but he should like to have an official statement on the point. Alderman Hacking said last month it was said the installation would be complete by the end of September, but he would rather they would allow the committee a little more latitude, for they could never be certain what the chapter of accidents might bring about. He would say this year, and he hoped long before the year was out. Councillor Hatch asked if the work of laying the main referred to by Alderman Hacking had been let by tender, and if it had been approved by the Council. Alderman Hacking said the cable had been contracted for, and the tender had been accepted by the Council. They required no tender for what they had in stock. The cable would be laid by their own men. Councillor Holland asked if it was the intention of the committee to introduce the electric light on the promenade. Blackpool had the electric light on the promenade; other towns were ahead of them in that respect, and with a beautiful promenade like theirs its lighting by electricity ought to have consideration before the lighting of the shops. Alderman Hacking said he did not think that was the business of the committee, but rather of the Council. They had not reached that stage yet, and the Council might do whatever it pleased. The Mayor: At present it is not included in the work contemplated. Alderman Hacking: No street-lighting is contemplated yet. The minutes were adopted.

Monmouth.—In our issue of the 31st ult. we gave some particulars of the report presented to the Town Council by Messrs. Bramwell and Harris on the electric lighting of the town. The subject has since been before the Town Council, when the Mayor observed that at their last Council meeting authority was given to himself to form a special committee to attend to the details of the electric lighting and sewage scheme. He would suggest that this committee remain in power until the work was completed. Afterwards it could be naturally divided and the drainage portion would go, as a matter of course, over to the Sanitary Committee, and then no doubt they would form a permanent committee to attend to the lighting portion of the scheme. That committee they could form when the scheme was completed. It was important to his mind that the engineers should be selected without further delay. There had been a great deal of preliminary work done, and the engineers would not proceed further without the Corporation signing the usual agreement with them. Their agreement with Messrs. Bramwell and Harris, as consulting engineers, whom he had recently seen, as well as Mr. Lailey, was

Digitized by Google

practically at an end. He had not known whether Messrs. Bramwell and Harris extended their work beyond that of consultation, and he had accordingly enquired on the subject, eliciting the reply that they were prepared to superintend the carrying out of the work at a commission of 5 per cent., plus out-of-pocket expenses. Mr. Wilson asked how they stood with regard to the Brush Company. The Mayor said they owed them 10 guineas for work they had already done. There was nothing more. He pointed out that the appointment of the Brush Company would prevent Messrs. Bramwell and Harris arranging and being associated with their own water power. Mr. Wilson said the Brush Company were prepared to look after the water power when the proposal applied to the water in the Wye. The Mayor: Personally I don't object to your suggestion, though I give the preference to Bramwell and Harris under the circumstances. Mr. Wilson: It is just possible the Brush Company may do it cheaper. Alderman Hyam: We shall not throw the Brush Company over. Mr. Morgan: Then we shall have three of them on the job. The Mayor: No, the Brush Company will come in as contractors The Mayor pointed out that Mr. Lailey had not the option of selecting his own site, and it was to the pumping station only that exception was taken by the Local Government Board. Mr. Wilson persisted that there was no idea before of having engineers to superintend the Brush Company. Before they were to have been engineers, contractors, and everything. The Mayor: We should have to put somebody on our behalf to look over them—an independent consulting engineer to superintend the fixing of the work. Now it is proposed that Messrs. Bramwell and Harris shall take that position. That is all. Mr. Wilson: I see. Messrs. Bramwell and Harris will occupy the position of architects, so to speak, and the Brush Company that of working contractors. The Mayor: Precisely. On Tuesday a special meeting of the Town Council was held to appoint an engineer to prepare plans and specifications for the combined scheme for drainage and electric light in the borough. After a protracted discussion it was decided, by seven votes to six, that Mr. Lailey, C.E., Westminster, be employed. The whole of the work connected with the electric installation, as well as the conveyance of the sewage from the pumping station to the purifying-tanks, is to be entrusted to Messrs. Bramwell and Harris. The minority wished to employ Messrs. Bramwell and Harris alone.

PROVISIONAL PATENTS, 1894.

SEPTEMBER 3.

16774. **Improvements in the construction and working of voltaic batteries.** Desmond Gerald FitzGerald, 53, Chancery-lane, London.

16775. **Improvements in voltaic batteries and electrolytic cells or tanks.** Desmond Gerald FitzGerald, 53, Chancery-lane, London.

SEPTEMBER 4.

16825. **Electromagnetic car brake and traction device.** Robert Thomas Murray and Charles Milton Allen, 60, Queen Victoria-street, London. (Complete specification.)

16851. **Improvements in or relating to underground electric railways.** William Phillips Thompson, 6, Lord-street, Liverpool. (Oscar Axel Enholm, United States.) (Complete specification.)

16854. **Improvements in continuous-current dynamo-electric machines without commutators.** Sydney Hopwood Blake, 70, Chancery-lane, London.

16857. **Improvements in telegraphy and in the means employed for perforating tapes used for this purpose.** Patrick Bernard Delaney, 24, Southampton-buildings, Chancery-lane, London.

16859. **Improvements in systems of electrical distribution.** Thomas Cornell Coykendall, 53, Chancery-lane, London. (Complete specification.)

SEPTEMBER 5.

16887. **Improvements in or connected with ships' telegraphic apparatus.** Hedley Oliver, 15, Water-street, Liverpool.

16912. **Improvements in electrical insulating compounds.** George Edward Heyl, 37, Chancery-lane, London.

16916. **An improved apparatus for manipulating lime and electric lights, and the boxes used therewith.** Henry Taylor, 106, Priory-park-road, Kilburn, London.

16918. **Improvements in access and junction boxes for electric conductors.** Alfred Fox, 46, Lincoln's-inn-fields, London

16939. **Improvements in apparatus for recording electric currents.** Hermann Aron, 6, Lord-street, Liverpool.

16943. **A new or improved portable ladder platform for the use of telephone or telegraph linesmen or the like.** Thomas Langlois, jun., 22, Glasshouse-street, Regent-street, London.

SEPTEMBER 6.

17000. **Improvements in electric arc lamps.** James William Rogers, 24, Southampton-buildings, Chancery-lane, London.

SEPTEMBER 7.

17047. **An improvement in electrical lock and block apparatus for railway points and signals.** Edward Tyer, 28, Southampton-buildings, Chancery-lane, London.

17065. **Improvements in or relating to electric cables, wires, or conductors for conveying electricity to vehicles or travelling motors.** Sebastian Ziani de Ferranti, 6, Lord-street, Liverpool.

17066. **Improvements in electric cables.** Sebastian Ziani de Ferranti, 6, Lord-street, Liverpool.

17077. **Improvements in lenses and electric lamps, more especially intended for use for theatrical stage purposes** Walter Pfeffer Dando and James Eglinton Anderson Gwynne, 47, Lincoln's inn-fields, London.

SEPTEMBER 8.

17129. **Improvements in electrically-heated soldering irons.** Paul Stotz and Friedrich Wilhelm Schindler-Jenny, 89, Chancery-lane, London.

17130. **An improved apparatus for electrically heating liquids.** Paul Stotz and Friedrich Wilhelm Schindler-Jenny, 89, Chancery-lane, London.

NOTES.

Electricity in India.—Rs. 18,000 has been sanctioned for lighting the Arkonam railway station with electricity.

Telegraphy in India.—The project for a telegraph line from Tavoy to Mergui has been abandoned for the present.

Institution of Civil Engineers.—The premises of this body in Great George-street, Westminster, are being reconstructed. The theatre is, however, to be left intact.

Telephony in Austria.—It is stated in Belgian newspapers that when the Austrian Government buys up the telephone lines it will issue a loan to provide the money.

International Exhibition at Bordeaux.—An international exhibition of arts and industry is to be held next year at Bordeaux. There are 10 classes, of which the ninth deals with electricity.

Telephony in Germany.—The Pforzheim Chamber of Commerce is in communication with the postal authorities for the establishment of direct telephonic communication between Pforzheim and Mayence.

A New Cape Steamer.—The "Guelph" is the latest addition to the fleet of the Union Steamship Company. She has been built by Messrs. Harland and Wolff, of Belfast, and is lighted electrically.

Electric Fans.—At the new Birmingham hospital there are two large revolving fans which propel the cleansed air and which are driven by electromotors. The premises are also lighted by electricity.

The Electro-Harmonic Society.—The next smoking concert of this society will be held on Friday evening next at the Banquet-room, St. James's Hall, Regent-street, W. We printed the programme in our last issue.

Exhibition at Stuttgart.—A proposal has been made that in connection with next year's opening of the Stuttgart central electric supply station there should be held an industrial exhibition, with electricity as a special feature.

Franklin Institute.—We have received the September issue of the *Journal* of the Franklin Institute of Philadelphia, which, among other matters, contains a paper by Mr. Thomas Commerford Martin on "Electricity in the Modern City."

The Heilmann Company.—The "Société Anonyme Traction Electrique, Système J. J. Heilmann," have held an extraordinary meeting of shareholders, at which it was decided to double the capital, which now stands at 1,000,000f. (£40,000).

The Houses of Parliament.—It is stated that during the present recess further progress is to be made with the scheme of electric lighting at the Houses of Parliament. There are many members who are much in need of enlightenment.

Electricity in South Australia.—The cost of lighting Parliament House, in South Australia, with electricity, formed the subject of a return laid before members by the Minister for Education. The total cost since its installation, including all costs of lighting during the 1891 session, amounted to £2,153. 18s. 10d.

An Electric Dairy.—At Blythwood, Stanstead, on Wednesday, Mr. and Mrs. James Blyth entertained upwards of 700 guests on the occasion of the visit of the British Dairy Farmers' Association to their electric dairy. The buildings are lighted electrically, and the cream separators and churns are worked by electromotors.

The Economy of the Electric Light.—Mr. William Whiteley, the "universal provider," of Westbourne-grove, states that he is saving £500 per annum in whitewashing alone by having adopted the electric light in his establishment. He adds that "there are many other advantages attaching to this system of lighting." Quite so.

Long-Distance Telephones.—A petition is being signed at Cardiff with a view of inducing the National Telephone Company to place that town in direct telephonic communication with the Metropolis. A similar movement in connection with the Post Office telephone system has been initiated by the Cardiff Chamber of Commerce.

Gas and Electricity Profits.—The Bradford Corporation in the last half-year made a profit of nearly £6,000 on their gasworks, and £336 on their electricity works. In the corresponding half-year the gasworks had a loss of £1,100. This indicates that the supply of the electric light is inducing gas consumers to burn more gas.

Electric Power in Germany.—The sugar refinery at Itzehoe, which is partly lighted electrically, is to receive a power transmission plant, comprising a 250-i.h.p. steam-engine, and 200 effective horse-power primary dynamo, and six electromotors of a total of 190 h.p. The work will be carried out by Messrs. W. Lahmeyer and Co., of Frankfort-on-the-Maine.

The British Museum.—The annual report relating to the British Museum states that the artificial lighting of the reading-room has been greatly improved by the installation of incandescent electric lights fitted to the reading desks. The old system of arc lamps is, however, still retained for the general lighting of the room, but at a lower power.

Cable-Laying in Scotland.—H.M.'s telegraph steamer "Monarch" arrived in Kirkwall Bay on Saturday. The vessel has been engaged laying cables on the west coast, and is engaged lifting the old cable in Ring Sound, replacing it with a new one. This cable crosses from the mainland to Shapinshay, and has been a private one, but is now expected to be made public and taken on to the Post Office.

Technical School at Bury.—Lord Derby has opened the technical schools at Bury. A fan driven electrically is used for taking off the fumes from the chemical laboratory combustion chambers. The closets are lighted by an automatic switch light, which switches the electric light on and off as the door opens or closes. The lighting throughout is by electricity, there being 211 lights in all, including two arc lights outside.

Heriot-Watt College. — We have received the calendar for the session 1894-95 of the Heriot-Watt College, Edinburgh. Although Edinburgh cannot be called an engineering centre, the classes connected with engineering subjects are very largely attended. In electrical engineering and applied physics the professor is Mr. R. Mullineux Walmsley, D.Sc., London, and the assistant professor is Mr. James A. Wilson, M.A., B.Sc.

Personal.—Mr. F. F. Bennett, M.I.E.E., of the firm of Bennett and Druce, Preston, has been appointed by the Radcliffe Local Board as their consulting and electrical engineer. He is also retained to prepare plans, specifications, etc., for the lighting of the town and district of Radcliffe, and to superintend the carrying out of the same. Mr. Hubert P. Marsh has been appointed teacher of electricity by the Rochester Town Council in connection with the local technical education scheme.

New Publications.—Messrs. Whittaker will issue shortly a new and mostly rewritten edition of Mr. Gisbert Kapp's "Electric Transmission of Energy" (as we have

Digitized by Google

already announced); "Model Engine Construction," by Mr. J. Alexander, with working drawings; "Steelworks Analysis," by Prof. J. O. Arnold, of the Sheffield Technical School; "Steam Power and Mill Work," by Mr. G. W. Sutcliffe, M.I.C.E.; and "The Manufacture of Modern Explosives," by Mr. Oscar Guthmann, A.M.I.C.E., F.I.C., etc.

Change of Address.—Messrs. Jeffery, Taylor, and Co. inform us that they have changed their address from Tidal Basin, E., to 11, Queen Victoria-street, E.C., where they will continue to carry on the business of electrical engineers, their speciality being house and ship lighting. They have recently completed installations at the Royal Albert Music Hall, Canning Town, E., where there are outside Jeffery arc lamps; at 159, Fleet-street, 303, Holborn, 151, Bishopsgate-street, and 160, Fleet-street, and have rewired several Royal Mail steamers.

Electric Lighting at Warsaw.—Offers have been received for lighting Warsaw electrically from Mr. Podobiedow, Mr. Paszkowski, and Mr. Timaszäjew, all of St. Petersburg; Mr. Ratner, of Warsaw; Messrs. Siemens and Halske, and the Allgemeine Elektricitäts-Gesellschaft, of Berlin; Messrs. Ganz and Co., of Budapest; the Oerlikon Works, of Switzerland; Mr. Waldeck, of Antwerp; and Mr. Berthol, of Paris. Further tenders are expected from other firms. The electric light is to be introduced in 1896, when the contract with the Continental Gas Company of Warsaw expires.

Telescopic Scaffolds.—As time passes on it is well we should find improvements effected in means for fixing and attending to arc lamps with greater facility and convenience, and Mr. Heathman, of Endell-street, is always striving to meet the requirements of electric lighting in the way of ladders. He is now constructing portable telescopic scaffolds, with his recent improvements, for the Norwich Castle Museum; the London and North-Western Railway Company, Crewe Station; the Great Northern Railway Company, King's Cross Station; the Bedson Wire Company, at Middlesbrough; Spitalfields Market; and Aberdeen railway station.

Electrical Accidents.—Somebody or other once referred to alliteration's artful aid, but it can be reduced to absurdity. The "dangerous dynamo" is the expression used by a juvenile sub. on a Tudor-street evening paper in connection with an accident which occurred at Leicester, on Monday, at the electric light station at the Midland Railway Company's station. If you want alliteration it sounds very well to refer to the "silly *Sun*," for it was not a shock from a dynamo, which killed the youth. He fell on to a flywheel and was knocked about, with the result of death. But such a death is not to be put down to electricity. You can get it in any works.

Union of Continental Incandescent Lamp Manufacturers.—Mr. G. Straus announces that the members of the union held their quarterly meeting from September 10 to 13 at Frankfort-on-the-Maine. Every member was present, and unanimously confirmed the resolution carried at the previous meeting. It was officially announced by the president of the meeting that communications had been received from several makers who had hitherto kept aloof from the association that they would like to join, and instructions were given for the management to make arrangements to meet these gentlemen and to arrange for them to join the union forthwith.

Yet Another Electric Launch.—The new electric launch "Maggie" ran her trial trip on Monday from the Barry Graving Dock and Engineering Company's works at Barry Docks, where she was wholly built, the run proving in every respect a successful one. There was a good company on board at the time, and the working of the new craft by means of electricity was much admired. This is the first electric launch built and fully equipped in South Wales. The electrical machinery was constructed under the supervision of Mr. D. Lowdon, M.I.C.E., A.I.E.E., for the Barry Graving Dock Company, the general manager of which, Mr. J. Lowdon, J.P., accompanied the boat on her trial trip on Monday.

What Are They About?—The Local Board of Sutton-in-Ashfield have extended the gasworks. They almost do not seem to know that the electric light is knocking about, although it is mentioned that the development of the electric light, and its application to several of the large factories in the town, has reduced the quantity of gas made, and for some considerable time the output from the gasworks has shown a falling off. The difficulty of supplying these factories previous to their adoption of the electric light was not so great as might at first sight appear, because the consumption by these works was mainly at night, when the shops in the town were closed, and when there was not such a strain upon the supply.

A Funny Notion.—The *Yarmouth Independent* says: "The Trinity Brethren can surely not be in earnest in their suggestion that the electric lights on the parade should be screened seawards. How can they possibly be any danger to ships at sea? We should think they would be a safeguard rather than a delusion, and would intimate to them their position. One single bright light might perhaps cause a little confusion until masters became acquainted with its position, but a line of lights along a parade can surely have no element of danger to the shipping. One of the advantages of the electric light on the Drive is that it lights up the beach, and if it were shaded on the sea side much of its utility and value would be gone. The electric light is used under similar circumstances in other places, and we hope no obstacle will be put in the way of its continuance here."

City of London School for Girls.—This school, which is situated in Carmelite-street, Thames-embankment, was opened on Thursday night last week. It owes its origin to Mr. William Ward, of Brixton, who left £20,000 to the Corporation for the purpose. The school is lighted electrically. On the occasion of the opening ceremony there was a display of electrical appliances illustrating the progress of telegraphy. The instruments, which were under the charge of Mr. J. W. Curra, included some curious old apparatus designed by Messrs. Cooke and Wheatstone, one of them having been in use in Buckingham Palace so far back as 1850. Another singular relic was a piece of wood containing fine laid wires which, in 1837, formed a portion of the telegraphic communication between Euston Station and Camden Town. Telegrams were dispatched from room to room by Wheatstone's A B C machine transmitting over 300 words a minute.

Electric Production of Sulphuric Acid.—Mr. R. W. Hill, of Manchester, writes that he has invented an electric apparatus for the production of sulphuric acid. The apparatus works quite automatically, and requires no manual assistance. If a leakage of acid somewhere takes place, an electric bell rings. The replacement of carboys (filled with ready-made concentric sulphuric acid, H_2SO_4, 66deg. Beaumé) takes place only once a week or fortnight, depending on the number of carboys, which vary from six to forty-eight or more as required. An electrical automatic hydrometer regulates the density of acid, thus any density of acid can be obtained. Sulphuric anhydride is produced direct

Digitized by Google

from sulphur dioxide (oxygen) by means of an electric current of low pressure. No platinised asbestos "chambers" or chimney are required for this new electro-chemical process. As soon as the empty carboys are full with ready-made acid an electric bell rings at the offices, thus signalling the fact that the filled carboys should be replaced by empty ones.

Electric Lighting in France.—It appears that the use of gas-engines for electric lighting purposes is making headway in France, and that this fact may lead to an understanding between the owners of gasworks and electric lighting concerns in cases where the former are unwilling to themselves undertake the supply of current. The *Génie Civil* draws attention to the installation at Rheims, which has been carried out under the direction of Mr. Théodore Vautier, of the group of gasworks which have their head-quarters in Lyons, and who was assisted at Rheims by Mr. André Coze, the manager of the local gasworks, one of the group in question. The central electric lighting station at Rheims at first comprised two 50-h.p. gas-engines, to which there have been added this year two 80-h.p. Niel two-cylinder gas-engines and a 45 h.p. Niel gas-engine. This is the most important electric station in France depending upon gas for motive power. There are two continuous-current C. E. L. Brown dynamos made by Messrs. Weyher and Richemont, of Paulin, running at 500 revolutions, and furnishing a current of 165 amperes at a variable pressure of from 240 to 300 volts. The efficiency of the dynamos is 88 per cent.

Electrolytic Works in Sweden.—A large electrical installation has been erected at Mansbo, Dalecarlien, Sweden, in connection with a chemical works where electrolytic processes are to be employed. The power station has been erected at the side of a waterfall in the neighbourhood, and 4,000 h.p. is available. At present there are eight turbines erected, each of 220 h.p. They have horizontal shafts, and run at 280 revolutions per minute, each being coupled direct to a dynamo. The dynamos are arranged in a row against a wall, which forms a dam to the upper part of the water. On the opposite side of the chamber in which the dynamos are placed there is a switch-board opposite each dynamo. The dynamos work independently, but in order to have a kind of reserve an arrangement has been made whereby each neighbouring pair of switchboards can be connected by means of a reserve cable. The dynamos have six poles and drum armatures, and have a normal output of 115 volts and 1,200 amperes, at which they have to be able to work day and night without interruption, though for a short time they can be considerably overloaded. The installation has proved most satisfactory, and it is proposed to increase it by 10 similar sets of turbines and dynamos. The electric portion of the plant was carried out by the General Swedish Electricity Company, of Vesteras.

Electricity at the Belgian Arms Factory.—We have on previous occasions given particulars respecting the electrical arrangements at the Belgian National Arms Factory at Herstal, near Liège. Some additions have been made to the plant, and the latest information appears in the *Times*, which says: "A very striking feature in connection with the Herstal works is the fact that the whole of the machinery is driven by electricity, the same agency being employed in lighting the factory and the yards. There were originally 13 electrical motors, having a total of 260 h.p., and a combined engine and dynamo of 500 h.p. These have been recently supplemented by an additional 300-h.p. plant. From the main generating dynamo the current is distributed to the various departments. In each department it drives a motor, which in its turn drives, through belting, a given length of main shafting. One great advantage of this arrangement is that each principal transmission shaft is under the control of its own electro motor, and is independent of the others. The particular characteristic of the main dynamo is that not only is it driven direct by the steam-engine, but the armature itself forms the flywheel of the engine. The first installation was put down three years ago, and it has been running continuously ever since most successfully and with marked economy. The supplementary installation is equally successful, and combines with the other machinery to make the Herstal works one of the most perfect of its kind."

Associated Chambers of Commerce.—At last week's meeting of the Associated Chambers of Commerce at Huddersfield, Mr. Plummer (London) proposed, and Mr. Thompson seconded, and it was resolved: "That this association expresses its hearty approval of the resolutions adopted by the inter-colonial congress recently held at Ottawa in favour of inter-Imperial postal and telegraph routes between this country and the colonies, and between the colonies themselves respectively, without such routes passing through other countries; and this meeting would urge on the postal and other governmental departments the importance of aiding, as far as possible, the proposals of the congress, and that memorials be sent to the Prime Minister, the Chancellor of the Exchequer, and the Postmaster-General." Mr. Eldridge (Wakefield) moved, "That in the opinion of this association, it is unfair to the public that the telegraphic department of the Post Office should for financial purposes be treated as a separate establishment, thereby causing unwarrantable delay in carrying out urgent and much-needed reforms: that, inasmuch as the postal establishment and its various departments are in their entirety a financial success, the time has arrived when the address of not exceeding four words should be allowed free of charge in all telegrams, and that telegraphic communication should be extended to rural districts where practicable; that a deputation wait upon the Postmaster-General to urge upon him the desirability of adopting this suggestion." Mr. W. Lester-Jones (Cardiff) seconded the resolution, which was passed. Mr. Walker (Huddersfield) moved, "That this association reaffirms the desirability of the law relating to the rating of machinery being settled in accordance with the principles in the Bill which was introduced into Parliament, and that her Majesty's Government be requested to give facilities during the next session for the passing of an Act to settle the law upon the subject." Mr. Slater (Leeds) seconded the resolution, and it was passed.

Rectifiers.—We referred last week in a note to the fact that Mr. Sidney F. Walker had again been on the war-path in the Welsh papers on the subject of rectifiers, which he described as "a laboratory toy." This has raised the ire of Mr. S. Z. de Ferranti, who writes in reply: "As a sub-contractor for a portion of the arc lighting work at Cardiff, you will perhaps allow me to say a few words on this subject. I cannot for a moment regard what Mr. Walker says in a serious light, but I must point out that what he says with regard to the arc lighting is without any foundation whatever. In the first place, the arc lighting by means of rectifiers in Cardiff has not been abandoned, and his kind congratulations on the subject are, therefore, quite superfluous. Mr. Walker goes on to say that he has persistently said that the use of rectifiers in Portsmouth has spelt trouble to all concerned. In doing this he has simply written that which is untrue, as the arc lighting by means of rectifiers at Portsmouth has proved the most complete success. The fact of being able to light the con-

Digitized by Google

tinuous-current arc lamps by means of rectifiers instead of by separate plant has greatly added to the economy and satisfaction of arc lighting, and therefore the system is is being largely adopted. Rectifiers and arc lamps working off them have been ordered by the Islington Vestry for the lighting of the main thoroughfares of this most important parish. Rectifiers have also been ordered, according to the specifications of Mr. W. H. Preece, chief engineer to the Post Office, for the lighting of Tunbridge Wells. Again, they have been ordered by Prof. Kennedy for lighting the principal streets of Edinburgh with arc lamps, and rectifiers have also been ordered for the extension lighting for the streets and sea-front of Blackpool by Mr. R. Hammond. There is not now a consulting engineer of any importance who has not got rectifiers on order for the arc lighting of the streets in the different towns of this country. I think that the above will be sufficient to prove how completely satisfactory this system of arc lighting has proved to be. The delays which have occurred in getting the station to work are simply what one may expect with any new enterprise, and if the Cardiff installation had been ready as quickly as many people would have liked, it is quite certain that it would have been the first case on record where the people were satisfied in this respect. It is very evident that there is not much left to be done before before a start can be made, and Mr. Massey's wise judgment in the matter will then be fully demonstrated. I consider that it is very unfortunate that Mr. Walker, who from the address at the foot of his letter—namely, Cardiff Electrical Works—might be considered to be officially employed by the Corporation, should be allowed to make rambling and false statements. Fair criticism is always desirable in the conduct of public enterprise, but criticism which is wholly without truth or reason can be nothing but bad."

Leeds Corporation and Electric Lighting.—The question of how, and by whom, the Leeds Town Hall and Municipal Buildings shall in future be lighted, has been discussed at a meeting of a special sub-committee of the Leeds Corporation. For a long time past the electrical plant in the basement of the Municipal Buildings has been a nuisance, the noise and the vibration caused by it being a source of considerable discomfort to those engaged in clerical work in the building. The matter first came before the committee in February last, when the city engineer was instructed to prepare a report upon "the question of the removal of the electric lighting station to one of the refuse destructors," it being thought that the waste energy at one of those places could be utilised. This report has been submitted to the committee. It appears that there are at present in and around the Town Hall and Municipal Buildings 3,131 incandescent lamps of 16 c.p., and 10 arc lamps of 2,000 c.p. The total cost for the year ended March last was £3,729. 6s. This included £1,022. 14s. 2d. for lamps, renewals, and attendance; £1,506. 12s. 4d. for mechanical power, and £1,200 interest and sinking fund. It was estimated that the cost of lighting by the present plant was 6·70d. per unit. The estimated cost, if the current were supplied by the House-to-House Electricity Company, was £3,383. 9s. 6d., or 6·57d. per unit. The estimated cost of electric lighting, supposing the current to be generated at the Kidacre-street destructor and led to the Town Hall, was 7·21 pence per unit. It seems rather singular at first glance that the cost at the Kidacre-street destructor should be the greatest, notwithstanding that the steam for the generation of power at that place would cost nothing. "This arises," says the report, "from the fact that £11,300 additional capital (inclusive of £3,000 for stand-by plant, absolutely necessary, though not provided in present plant) is required for that place, and that this £11,300, added to the capital of leads, lamps, etc., in the buildings, has to be met with an annual payment of 12 per cent. The result of this speedy repayment would be that in 10 years the debt would have been cleared off, the annual cost would be reduced some £1,100, or 2·15d. per unit, making the cost at Kidacre-street thereafter 5·06d. per unit as compared with 6·57d., the cost if the supply is taken from the House-to-House Company. Another feature in favour of the Corporation generating the electricity at Kidacre-street, or, indeed, anywhere, is the fact that should the Corporation in the future buy out the electricity company, it would not have to buy out the profits on its own custom, which on the present consumption of electricity would amount to about £3,300. After a lengthy discussion, the committee resolved to recommend the Council to accept their electrical supply from the House-to-House Electricity Company for a period of two years at a price to be agreed upon. If the Council carry out this recommendation, the present plant will remain in the Municipal Buildings in case it may at any time be required.

First Aid in Electric Accidents.—Dr. W. S. Hedley, of Brighton, writes to the *Lancet* as follows: "For the information of those who are not medical men and electricians, the article on the pathology and treatment of electric accidents in the *Lancet* of August 25 may be suitably supplemented by briefly adverting to the question of first aid in such cases, and to certain risks attendant thereon. It is obvious that the first thing to do is to detach the body of the victim from the circuit with which it is contact; but it is equally obvious that, as that body is forming part of the circuit, it would be dangerous to touch the skin with bare hands, inasmuch as anyone doing so would thereby 'shunt' a portion of the current through his own body. The clothing, if dry, would afford a considerable, but not quite adequate, protection; it is therefore necessary to improvise some kind of insulation for the hands of the rescuer. Further, as is well known, the muscles of a body traversed by an alternating current of high tension remain in a state of tonic contraction. In other words, a hand grasping a cable remains tightly clenched (the condition of 'fixation'), and detachment is not always easy. Such accidents generally occur by the completion of a circuit between the cable and the earth, but sometimes contact is made simultaneously with both poles of a circuit. The time seems to have arrived for the publication of some carefully considered authoritative code of instructions for the management of such accidents as well as for their prevention; in the meantime, however, such considerations as the foregoing would appear to point to the following: Rules for guidance in electric accidents—(1) Break the circuit at once if there be an interrupter close at hand and you know how to use it; if not, lose no time, but proceed to Rule 2. (2) Do not touch the man's body with your bare hands, but if indiarubber gloves are not at hand, pull him off the cable by his coat-tail, or fold your coat or some such dry article into two or three thicknesses, and, using this as a pad to take hold of the body, pull it away from the circuit and resort to Rule 5. (3) If unable to get him off, raise with covered hands that part of the body which is touching the earth, or one of the poles of the circuit. This will break the circuit, and it will usually be thus possible to get him easily away, and, if so, proceed to Rule 5. (4) If still unsuccessful, make another pad, and, placing it between the ground and that part of the body in contact with the ground, continue your efforts to detach him. (5) Having pulled him away from the cable, free his neck from clothing, and treat the case as one of

Digitized by Google

drowning, one method being as follows. (6) Open his mouth, and, taking hold of the front part of the tongue with your fingers—covered with a handkerchief if you have one—draw the tongue forwards, and gradually let it go back 16 times a minute. Be sure that the root of the tongue is acted upon and drawn forward. If the teeth are clenched and you cannot get them apart with your fingers, gently separate them with the handle of a pocket-knife or by a small piece of wood, cork, etc. (7) Resist the efforts of the bystanders to pour stimulants down his throat until a medical man arrives and 'takes over' the case."

The Effects of Lightning.—Mr. T. W. Carmalt Jones writes as follows to the *Lancet*: "By the same post I am sending you the skin of a rabbit, which has simply been rubbed over inside with table salt. When we, a party of five, were at lunch in the keeper's cottage in Kingswood, near Woodstock, this afternoon, there was some thunder about. About a quarter past two there was a tremendous crash with a blaze of light—the light reddish, certainly not blue—and we all felt more or less shaken, and were certain that the lightning had struck somewhere very near us. We soon found that a tree 35 yards from the cottage had been struck. The bark had been ripped off the tree in two streaks between 2in. and 3in. wide, and some of it was hanging in strips from the tree, and pieces of bark in small pieces and in strips were lying for a distance of at least 10 yards all round the tree. The tree was a larch, and the tallest near us, and was estimated by an architect and a builder, who were of our party, to be at from 55ft. to 60ft. in height. At the foot of the tree, about 1ft. from its base, we found a rabbit lying dead. It is the skin of this rabbit that I am sending you. You will see where the electricity has scorched off the fur, and we all noticed that there was a distinct smell of burning about the rabbit. The latter was quite warm and limp, and lying on its side, the eyes being open and quite bright." The following is the editorial comment on this subject: "The letter of Mr. Carmalt Jones, which is printed in another column, though it does not seem to present any absolutely new feature in connection with occurrences of the kind in question, is interesting in more ways than one—chiefly, perhaps, from the point of view of the rabbit. The 'skin' sent to us shows a space of about 6in. in length and about 1in. in width denuded of fur. The bare skin is slightly desiccated, but not discoloured, vesicated, or charred. It is presumed that there was no further sign of injury or disorganisation of tissue in the rest of the body of the animal. This is consistent with the known fact that electric discharges, even when fatal, do not necessarily kill by producing any gross change in the tissue and organs, or even, so far as is known, by altering the histological elements of a structure. The damage to the tree is simply the disruptive effect of the lightning flash striking an imperfect conductor. The men 'felt more or less shaken.' In other words, they experienced a shock due to induction. Owing to the presence of a 'charged conductor' in their neighbourhood a charge of opposite sign had been induced in them. When the flash occurred—*i.e.*, when the conductor was discharged—the induced charge in their bodies was also suddenly discharged. This is known as 'return shock.' The distance recorded in this case is not too great for such effects to be experienced. It was very different in the recent balloon accident at Aldershot, where four men holding a captive balloon by a wire rope were 'struck' and seriously injured. In this case the unfortunate men had by means of their balloon simply angled for the lightning, and, having captured it, offered it a ready route to earth through their own bodies. It is a source of astonishment as well as of regret that, in the light of historic experiments with lightning and kites, such an accident as this should not have been foreseen and provided against."

The Pacific Cable.—Sir Adolphe Caron, Postmaster-General of the Dominion of Canada, is at present in this country, and has been interviewed by the *Daily Chronicle*. He was asked what progress was being made in carrying out the recommendations of the inter-colonial conference, of which he was vice-president. It was evident from his replies that material progress is being made. The Dominion Government has called for tenders for the proposed cable across the Pacific, and the Postmaster-General has, while in London, seen Mr. Alexander Siemens, who expresses himself confident that there is nothing standing in the way of the immediate construction of the Pacific line, at a cost of £2,000,000, if three years be allowed for construction, or £2,030,000 if a shorter time is given. Mr. Siemens does not even admit that a prior survey of the route is necessary. "He knows the Pacific along the line where the cable would run as well as he knows his own bedroom," said Sir Adolphe. "These are not his precise words, but they convey what he meant. Electrical science has, he says, made such progress in recent years that there is now no difficulty in laying cables even at great depths." Sir Adolphe was reminded of the tale published in American journals that the provisional Government of Hawaii had managed, upon a premature statement by Mr. Reid, the Victorian Minister, to frustrate the alleged intentions of her Majesty's Government to acquire Neckar Island as a landing-place for the cable, and had dispatched a steamer to annex the island to Honolulu territory. But Sir Adolphe was not to be drawn. He could not, he said, make any public statement. Evidently, however, he did not feel much disconcerted by the alleged action of the Honolulu authorities, and thought it most probable that now Hawaii was politically at rest, the advantages of direct cable communication with the American continent would make the Hawaiian Government sympathetic towards the proposal. It was also to be inferred that the matter is engaging the close attention of Lord Kimberley. As for the other recommendation of the conference, Canada was charged by the assembled delegates to push them forward, and Sir Adolphe declared that she would not be slow to fulfil this mission. It was, he thought, quite among the possibilities of the future that events would be rife for another inter-colonial conference perhaps next year, and the meeting-place might then very well be in one of the Australasian colonies. These matters move so fast when the initiative lies in colonial hands. The *Chronicle* yesterday stated: "The New South Wales Government has, it is announced, decided to co-operate with other Australasian Governments in protesting to the Imperial authorities against the annexation of Neckar Island by Hawaii, and combined action on the part of the Agents-General is talked of. We fancy Mr. Reid and his colleagues will find that their protest comes too late. If Neckar Island does not belong to Hawaii by natural right, to whom does it belong? It certainly does not belong to us, and, barren rock land that it is, we never thought of claiming it until a resting place was needed for the proposed trans-Pacific cable. As a matter of fact, the merchants and Government of Hawaii are themselves as eager for the Pacific cable as are the Australians, and those who should know do not think any serious difficulty will be raised when it becomes a question of seeking a neutral landing place for the cable within the Hawaiian territory. Whatever is done must, however, be the outcome of friendly communications; to talk of protests seems out of place."

MECHANICAL TRACTION FOR TRAMWAYS.

(Continued from page 300.)

In dealing with mechanical tramway traction systems, it has been stated that the author classifies these according as the operative energy is produced at a central point and distributed in various ways to motors upon the cars as they travel along the road; or, secondly, the cars themselves are made to carry sufficient raw energy material or stored energy to run continually between terminal points for some length of time.

Taking the former into consideration first, so far as they include electric working, it may be said that the general principle of action upon which they are based is the following: motive power is produced at some fixed point, and is caused to operate electric dynamo generators. The energy of the latter is transmitted along conductors fixed over the entire length of tramway to electric motors carried on the cars, to the axles of which they communicate a rotary movement. Such a plan obviously differs from a cable or wire-rope system in so far as it involves a transformation of energy, and does not use the latter in its primary form as derived from the motive-power station; but since this transformation is highly efficient and offers great advantages of distribution, it does not actually involve more waste, expense, or trouble than that which follows from using an endless wire rope for traction purposes.

There are obviously three distinct parts or characteristic features in an electric traction system of this kind:

1. The production of energy in a central station.
2. Its utilisation by electric motors upon the cars.
3. The connecting link between these two—*i.e.*, the line of conductors along the route serving to connect the fixed generators with the travelling motors.

The author then proceeds to consider the latter section, and shows that an initial difficulty presents itself at once. The electric motors are in actual motion along the line—that is, are continually moved from point to point with the cars on which they are fixed. This necessitates also a moving contact or point of communication between each car and the fixed conductor along the way, and great care must be exerted to make this contact as good as possible. This line conductor must be separated or isolated from surrounding bodies. There are conceivably three different positions for such a conductor: it may be above the ground level, at the same level as the rails, or, finally, underground. The first and third evidently form the only two methods which are practically suitable for tramways whose permanent way or road bed is not specially constructed or fenced off. Each system or arrangement of line conductor is described and discussed briefly by the author, but he states nothing in any way novel or of striking interest, beyond what is now well known to all our readers, both historically and technically.

For overhead conductors he takes as the typical arrangement that of the Thomson-Houston Company, so largely employed in the United States, and to an increasing extent at the present time upon the European Continent, but does not forget to trace the development of this system from the early electric tramways of Messrs. Siemens and Halske, dating about 13 years back, and based upon the use of two overhead channel conductors, positive and negative, or lead and return.

The Portrush and City and South London lines are cited as instances of the second method of fixing the line conductor, whilst Blackpool and Budapest provide examples of the third, involving the use of an underground conduit, along which the conductor is placed upon insulators.

Turning from the line and permanent way to the central station, where the necessary energy is produced for operating the cars, the author recognises three constituent parts or features of special importance. These are:

1. The boilers and engines, water motors, or other prime movers used to actuate the electric energy-developing machines.

2. The dynamo-electric generators which transform mechanical energy into electric energy.

3. The apparatus used for regulating and controlling the current of electric energy passing outwards to the line conductors.

On a line with considerable grades, the work absorbed by the cars varies enormously from instant to instant, the resistance on a grade of 6 per cent. being seven times that of the level with an ordinary track: and a corresponding amount of power must be provided at the central station. With a small number of cars on the line—each one pulling up, stopping, and restarting irrespective of the others—the variation in output from the central source of power is very high; for instance, with less than eight cars at work on a somewhat uneven road, the maximum output will often be twice as much as the average. The prime movers and electric generators must therefore be calculated to withstand these sudden variations in the power required on the line.

As a rule, the current is distributed along the line in such fashion that the different car motors are all connected in parallel with the line conductor at a potential as constant as possible. The amount of current therefore varies within limits corresponding to the changes in output from the station, and it rises by no means infrequently from zero to the maximum in a few seconds. This leads to the adoption of special arrangements in the electric generator in order to secure a tolerably constant E.M.F., these machines being what is called "over-compounded." The usual E.M.F. employed averages 500 volts, and with a maximum 10 per cent. loss in the line, the terminal E.M.F. is therefore 500 volts at no load and 550 volts at full load.

The speed of the dynamo must also be kept as constant as possible, whatever the load; and this implies the use of engines or prime movers with very sensitive and quick-acting governors, not allowing a variation in speed of more than 2 to 3 per cent. In cases of great differences in the output—when, *e.g.*, the maximum reaches double the average—it is often preferable to use high-speed engines or other motors, provided with heavy flywheels, either coupled direct to the dynamos or driving them by means of belting. For more regular work engines of a slow speed and more economical type may be employed.

It is usual to keep the brushes on the electric generators in a constant position: sparking at the commutators is avoided by using carbon brushes, and by varying the generator magnetic field in accordance with the output.

Each car, of a capacity equal to 50 passengers, and weighing loaded about 10 tons, may be said to absorb from 6,500 to 7,000 watts on a well-built level road at a speed of from 6¼ to 7½ miles an hour. With moderate grades, this corresponds to an output of 11 h.p. to 12 h.p. at the central station; the capacity of the latter ought, however, to be sufficient for a possible demand of double this amount at least. The Thomson-Houston Company, says the author, calculate upon using one 60-kilowatt dynamo when four cars are on the line, and one 100-kilowatt machine for seven cars at work—that is, from 13,000 to 15,000 watts per car. Boiler capacity is reckoned at about 120 square feet of total heating surface per car on line.

When the network of lines covers only a small area, the current is, as a rule, sent out from the station along the trolley wire, but as the tramway system extends, other wires are carried along also to act as "feeders," thereby keeping down the waste of energy due to line resistance, and at the same time avoiding the necessity of a larger trolley wire. The latter is thus maintained at a diameter of some eight or nine millimetres (equal to, say, No. 0 S.W.G.): the feeders are run direct from the central station to different points of the lines best calculated to maintain a uniform potential over the whole network. In cases where large currents are required, the feeders are supplemented by an underground conductor carried along parallel with the line conductor, to which it is joined at proper intervals. The generators at the station are usually connected in parallel, and any one of them may, on emergency, supply current to any isolated section of the network.

In some instances the supply of current along the line is provided by a central station, already in existence, for the purpose of lighting adjacent districts: and a combination of this kind obviously offers great advantages, because it gives a practically continuous load for the generating machinery for at least two-thirds of the day and night.

Digitized by Google

The working cost per unit of energy is thus very considerably reduced, and the expenses of operating both the lighting and traction systems are correspondingly less. The usual E.M.F. of dynamo generators for electric lighting purposes on a low-pressure system is, however, insufficient for the higher potential employed on an electric tramway, and this necessitates the use of continuous-current transformers, which raise the voltage from that of the lighting circuits (125 to 250 volts) to that of the tramway line conductor (500 to 600 volts). Such transformers need not necessarily be placed in the central station, but can be fixed at any convenient point whence distribution over the tramway network is the easiest and most economical.

Passing from the development of electric energy in the central station to its use in the motors on the cars, the author discusses the question of motor winding in its effect upon the tractive force or motive couple. The amount of the latter developed in a motor armature rotating in a magnetic field of strength H under the application of a current having an intensity equal to c is proportional to the product of these two, or $C = K \times H c$. Also, if E represents the line E.M.F., e the counter E.M.F. developed in the motor, and R the resistance of the circuit, we have the following relation between them:

$$e = E - R c.$$

Again, e is proportional to the value of the magnetic field, H, and the angular speed of rotation in the motor, ω; or

$$e = k \times H \omega.$$

Obviously it is advisable that the speed of rotation in the armature should vary as little as possible with the resistance to be overcome—that is, the car speed should be kept up whether travelling up or down, or on the level.

In the case of shunt-wound motors, the magnetic field is practically constant, especially when the magnets are near saturation, because then the armature reaction has only a very small effect. The counter E.M.F. is diminished in proportion as the current rises: but if the internal resistance of the motor is kept purposely small, the diminution in e is also less in comparison with E, the line E.M.F.

Under these conditions the speed of rotation is kept almost constant, and the car will travel at practically the same velocity whatever the grade may be. The current, on the other hand, will increase in proportion to the work to be done, and on very steep grades may attain an excessive value in regard to the safety of the motor, unless the latter is constructed of a size and weight far beyond what is required for the average output.

This system of winding is therefore seldom employed. Preferably means are used for increasing the value of magnetic field and current upon which the static effort depends, in order to develop a large power at starting for heavy loads or steep grades without necessitating dangerously large currents in the motor armature. Moreover, with the comparatively high voltages employed, a shunt winding implies field magnets of too delicate and costly a type for continuous working.

It may be remarked, incidentally, that such obstacles to the use of shunt-wound motors do not possess the same importance for lines where the resistance is more uniform; say, for instance, on ordinary railroads. In these cases the magnetic field may with advantage be kept constant either by a shunt winding or separate source of excitation. This latter method is used, it will be remembered, on the Heilmann locomotive.

With series-wound motors the couple, $C = K \times H c$, reaches its maximum value, thereby giving an easy and powerful starting effort upon steep grades. To prevent excessive variations in the car speed under normal conditions, and to reduce the amount of armature reaction, the winding upon the field magnets is designed to give a very powerful magnetic field, almost saturated, when the average current passes. The lead of the brushes may then be reduced to nothing without any sparks at the commutator. This arrangement also makes the counter E.M.F. developed in the armature much less sensitive to the current variations.

The speed of rotation depends upon the current value. When the latter increases, the counter E.M.F. is less, whilst the magnetic field is more powerful. The speed will accordingly continue to fall in proportion as the current increases—that is, in proportion as an increasing resistance in the line calls for a greater tractive effort. The variations thus noted may be effected artificially by changing the internal resistance, interposing, for instance, a rheostat in the circuit.

In going down hill the magnetic field becomes weaker, and the speed of rotation increases out of all proportion. The use of a resistance in the circuit, however, checks this increase in speed by reducing the E.M.F. at the motor terminals; but this procedure, of course, involves a considerable loss, which reduces the general efficiency to no small degree.

The efficiency of the motor depends upon the relation of e to E—that is, of $k \times H\omega$ to E. It depends principally upon the speed of rotation, ω, for the magnetic field, H, cannot increase beyond certain limits; it has, indeed, a certain maximum value, however great should be the current strength. Consequently, at starting (when the speed of rotation stands at zero) and at points on the line where the requirements of traffic cause the car speed to materially decrease, the efficiency is very small. There is accordingly a loss at every stoppage or reduction of speed, independently of the energy taken up by the brakes, and the sum of these losses will attain a considerable amount on tramway lines where frequent stops are the rule.

(To be continued.)

A GENERAL THEORY OF THE GLOW LAMP.*—I.

BY H. S. WEBER.

The phenomena of the glow lamp are perhaps the simplest in the domain of radiation. The lamp consists of a conductor in a nearly complete vacuum, traversed by an electric current, under the action of which it is heated to a stationary temperature such that the radiation from its surface consists in considerable part of visible rays. The simplicity of the conditions lead to the supposition that between the size and the temperature of the radiating surface, the wave-length and intensity of radiation, and the quantities by means of which the electrical energy developed in the filament are determined, there exist relations which are capable of expression in some simple form.

Up to the present time only purely empirical attempts have been made to determine the relation between the amount of light emitted by the glow lamp and its electrical constants. Jamieson and Preece believed the brightness of the glow lamp to be proportional to the sixth power of the strength of the current. Voit concluded from the observations of Jamieson, and from numerous measurements made at the electrical exhibition of Munich upon many varieties of lamps, that the light was approximately proportional to the third power of the energy expended. Hess has shown that whenever the range of intensities becomes considerable, a member must be added to Voit's expression which is proportional to the energy. Finally, Slotte has drawn the conclusion from simultaneous measurements of the strength of the current and the intensity, that the light of the lamp is closely related to the fourth power of the current strength.

These experimental investigations could lead to no final result, since the most important element—viz., the temperature of the glowing filament—was left altogether out of account. Finding that the means of determining this temperature were lacking, only the most unreliable estimates concerning it, running from 2,250deg. to 1,200deg., being attainable, I have spent several years in an attempt to establish an exact physical theory of the electrical incandescent lamp which should cover all the observed facts, and have for this purpose made exact measurements upon more than 30 types of lamp, in order to determine the characteristic properties and to obtain the values of such constants of radiation for carbon as are necessary to a completion of the theory. I believe that I have now reached a point in these attempts where all the phenomena

* A paper read at the Frankfort Congress for Electrotechnics. Translated for the *Physical Review*, from which this is reprinted.

Digitized by Google

of the incandescent lamp may be expressed by means of a few formulæ. Permit me to report briefly in the following pages the results of my investigations.

I.

The starting point of my work was the establishment of a general expression by means of which the intensity of homogeneous radiation of a given wave-length emitted by a solid body at a given temperature might be expressed in terms of the wave-length and temperature, and of the size and nature of the radiating surface. No such general formula existed in the realm of radiation.

In 1888 I showed that the result of a great variety of observations could be expressed in this form :

$$d^2 s = \frac{d\,\mathrm{F} \,.\, d\,\mathrm{F}_1 \,.\, \cos w \,.\, \cos w_1}{r^2} \cdot \frac{c}{\lambda^2} \cdot e^{a\,\mathrm{T}} \quad \frac{1}{b^2 \lambda^2 \mathrm{T}^2} \quad (1)$$

in which $d\,\mathrm{F}$ is an element of surface of the radiating body, $d\,\mathrm{F}_1$ an element receiving this radiation, r the distance between the two elements of surface, w and w_1 the angles between the elements of these normals and the direction of the line joining them, r. This equation expresses the amount of energy of homogeneous radiation of the wave-length which is sent out from the surfaces of the element $d\,\mathrm{F}$ at the absolute temperature, T, to the surface of the element $d\,\mathrm{F}_1$ in the unit of time. In this equation e has the usual signification; a is a constant common to all solids—viz., the value 0·0043; b^2 is a constant which should have the same, or nearly the same, value for various bodies; and, finally, c is a constant which varies from substance to substance. To distinguish them, I have named these three respectively constants of temperature, a, the illuminating power, b^2, and the constant of emissivity, c.

From equation (1) it follows, in the first place, that the amount of energy radiated from the entire surface, F, in all directions in the unit of time is

$$s = c \,.\, \pi \,.\, \mathrm{F} \,.\, e^{a\,\mathrm{T}} \quad \frac{1}{b^2 \lambda^2 \mathrm{T}^2} \quad . \quad . \quad (2)$$

This quantity is to be called the intensity of homogeneous radiation.

It follows, further, that the sum of the intensity of all the homogeneous rays which are emitted at the temperature, T (the total radiation of the body) is expressed by the equation—

$$\mathrm{S} = \int_{\lambda=0}^{\lambda=\infty} s \,.\, d\,\lambda = c \,.\, \pi \,.\, \mathrm{F} \,.\, \frac{\sqrt{\pi}}{2} \,.\, b \,.\, \mathrm{T} \,.\, e^{a\mathrm{T}} = \mathrm{C} \,.\, \mathrm{F} \,.\, \mathrm{T} \,.\, e^{a\mathrm{T}} \quad (3)$$

The quantity $\mathrm{C} = \frac{1}{2}\pi\sqrt{\pi c \,.\, b}$ is to be called the constant of total radiation.

If the radiating body, k, is placed in an enclosed space, the walls of which have the common temperature, T_0, the total loss of energy which k suffers in consequence of the radiation in the unit of time is given by the formula

$$\Delta\,\mathrm{S}_{\mathrm{T},\,\mathrm{T}_0} = \mathrm{C} \,.\, \mathrm{F}\,(\mathrm{T} \,.\, e^{a\,\mathrm{T}} - \mathrm{T} \,.\, e^{a\,\mathrm{T}_0}), \quad . \quad (4)$$

it being assumed that the surface, F, of the radiating body is very small as compared with the surfaces of the surrounding walls, an assumption which is admissible for all incandescent lamps. I have assured myself that equation (2) expresses the result of all trustworthy measurements hitherto made upon the relation between wave-length and temperature of homogeneous rays. And it can be shown also that equation (4) agrees completely with the carefully determined results of Schleiermacher upon the total radiation of platinum, and the oxide of copper for temperatures between 273deg. and 1,173deg. Measurements of my own upon the total radiation of carbon between 300deg. and 700deg. were also capable of being expressed by formula (4).

II.

Equation (4) affords a simple method for the determination of the temperature of the glow lamp. After the temperature of the filament under the action of the current has become stationary, the amount of energy developed by the current in each unit of time plus the energy which the filament receives from the surrounding walls is equal to the energy which it gives out, so that for every such time-interval the equation—

$$\Delta\,\mathrm{S}_{\mathrm{T},\,\mathrm{T}_0} = \mathrm{C} \,.\, \mathrm{F}\,(\mathrm{T} \,.\, e^{a\mathrm{T}} - \mathrm{T}_0 \,.\, e^{a\mathrm{T}_0}) = i \,.\, \Delta\,\mathrm{P}$$

holds true, where i and $\Delta\,\mathrm{P}$ are the current intensity which is regarded as constant, and the difference of potential between the terminals of the filament, respectively.

In the case here assumed, where $\Delta\,\mathrm{S}_{\mathrm{T},\,\mathrm{T}_0}$ is given in heat units, the equation takes the following form :

$$\Delta\,\mathrm{S}_{\mathrm{T},\,\mathrm{T}_0} = \mathrm{C} \,.\, \mathrm{F}\,(\mathrm{T} \,.\, e^{a\,\mathrm{T}} - \mathrm{T}_0 \,.\, e^{a\mathrm{T}_0}) = \frac{i \,.\, \Delta\,\mathrm{P}}{\mathrm{J}},$$

in which J is the mechanical equivalent of the calorie. It follows from this equation that by means of measurements of the quantities i, $\Delta\,\mathrm{P}$, T, and F, the temperature of the filament can be determined, provided the constant, C, is known. This can be found by the estimation of the stationary temperatures which the filament attains under the action of known currents and potential differences. The value of these temperatures is given from the resistance of the filament, provided the dependence of resistance upon temperature has been determined by a series of experiments for the intervals of temperatures not given. The following table gives an example of the determination of the constant, C, the total radiation of the filament of a specimen of the new Cruto lamp, the surface of which had been found by the length of the carbon and its cross-section at 11 points distributed along the filament at equal distances. This surface was found to be 0·647 square centimetre. The resisting value of C = 0·0000171 refers to gramme-calories, centimetres, and seconds.

NEW CRUTO LAMP.

F = 0·647 square centimetre.

$\mathrm{M} = 171·8 \times 10^{-7}$.

Following this plan, I have in the course of years determined the constant of total radiation for 33 varieties of glow lamp. The summary of the results obtained shows that these 33 filaments belong to two groups. Three carbons—that of the Edison lamp, the new Cruto lamp, and of the lamp of Woodhouse and Rawson—have a radiation coefficient of 0·0000169 and 0·0000174; while 30 filaments give for the radiation constant values between 0·0000127 and 0·0000132. The three carbons first named are black; the others show grey surfaces. The mean value of C for these two different varieties of filament stand in the relation of 100 to 75·5. This is almost exactly the same relation which Leslie, at the beginning of this century, found for lampblack and graphite—viz., 100 to 75. It may, therefore, be asserted that incandescent lamp filaments with grey surfaces should be classified as graphite carbons.

A knowledge of the constant, C, makes it possible to determine the temperature of the filament for every condition of incandescence when we know the size of its radiating surface. It is interesting to know what the temperature of the filament is when the incandescent lamp is in operation at normal brightness. The result is a surprising one—viz., that the normal temperature of all sorts of lamps is very nearly the same, and is included in an interval between T = 1,565deg. and T = 1,580deg. of the absolute scale. In the case of some lamps of very great brilliancy—that is to say, of lamps with thick filaments, which can be brought to higher temperatures without

Digitized by Google

serious damage, and which can consequently be operated at higher economy—we find the normal temperature to be about 40deg. higher.

It is, further, of importance to know between what temperatures the filament changes when the candle-power of the lamp is varied through considerable range—from two candles to 30 candles for a 16-c.p. lamp, for example, or from 20 to 300 candles in the case of a 200-c.p. lamp. The result of measurements shows that the temperature variations which correspond to such changes in brightness amount to about 180deg. In practice, accordingly, glow-lamp illumination covers a range extending from 1,400deg. to 1,600deg. for small lamps, and 1,450deg. to 1,650deg. for large lamps. If we confine ourselves in the study of incandescent lamps to this range of temperatures, we may write, in place of equation (5) the simple form—

$$\Delta S_{T, T_0} = C . F . T . e^{aT} = \frac{i \Delta P}{J} \quad . \quad . \quad (6)$$

since in these cases the quantity $T_0 . e^{aT}$ is very small as compared with the quantity $T . e^{aT}$. This is shown by the following small table:

T_0	$T_0 . e^{aT_0}$	T	$T . e^{aT}$
273+50°	$1\,295 \times 10^3$	1,400°	576×10^3
+75°	1·554	1,450°	740
+100°	1·854	1,600°	1,554
+125°	2·203	1,650°	1,989

In this simpler form equation (6) indicates in what degree the current must increase in order to bring about a given rise of temperature in the filament. To make this matter clearer, I have drawn up the following table:

T	$T . e^{aT}$	T	$T . e^{aT}$	T	$T . e^{aT}$
1,400°	576×10^3	1,500°	948×10^3	1,600°	$1{,}554 \times 10^3$
1,410	606	1,510	996	1,610	1,634
1,420	637	1,520	1,047	1,620	1,717
1,430	670	1,530	1,100	1,630	1,803
1,440	704	1,540	1,156	1,640	1,894
1,450	740	1,550	1,214	1,650	1,989
4,460	777	1,560	1,276	1,700	2,541
1,470	816	1,570	1,340	1,800	4,136
1,480	858	1,580	1,408	1,900	6,712
1,490	902	1,590	1,479	2,000	10,860

From these data, and from the expression

$$\frac{d(T . e^{aT})}{dT} \cdot \frac{1}{T . e^{aT}} = \frac{1}{T} \, t a,$$

it may be seen that for the entire range of temperature from 1,400deg. to 1,600deg. the following simple law holds true—viz., that every increase in the energy of the current amounting to ½ per cent. raises the stationary temperature of the incandescent lamp 1deg.

To show in greater detail the changes which the filament suffers by change of current and potential difference, and the changes which the resistance of the filament and the amount of light emitted suffer through change of temperature, I introduce the four following tables, which may also serve to indicate the manner in which the investigation of 33 types of incandescent lamps was carried out. In the eight vertical columns of the tables are given respectively 10 values: the strength of the current, i; the difference of potential, ΔP; the resistance, W; the energy, E; the candle-power, H; the quantity, $\frac{H}{E_3}$; the efficiency, $E_1 = \frac{E}{H}$; and the absolute temperature, T. As unit of brightness, the British standard candle has been selected, and H denotes the mean horizontal intensity. Of the lamps to which these four tables refer, two had black carbons and two grey carbons. The quantity R in each table refers to the radiation factor for brightness—the factor, namely, by which the mean horizontal candle-power is to be multiplied in order to get the mean spherical candle-power. These quantities were determined by measuring the lamp in 132 positions, as evenly distributed through space as possible.

PRACTICAL NOTES ON DYNAMO CALCULATION.* XIII.

BY ALFRED E. WIENER.

(Continued from page 310.)

28. *Dimensioning of Commutator—(a) Diameter and Length of Brush Surface.*—In low-potential machines with small number of divisions, the thickness of the substructure determines the diameter of the commutator; in high-potential machines, however, especially those of multipolar type, where the number of commutator segments is very

* From the *Electrical World* (New York).

Digitized by Google

great, the width at top of the commutator bars, their number, and the thickness of the insulation between them fix the outside diameter.

The bars must be large enough in cross-section to carry the whole current generated in the armature without undue heating, and shall continue so after a reasonable amount of wear. They must be of sufficient length to allow a proper number of brushes to take off the current.

The same brush contact surface may be obtained by employing either a broad thin brush on a small-diameter commutator or a narrow thick one a large diameter, the number of bars being the same in both cases, their width, consequently, larger in the latter case. With larger diameter and greater consequent peripheral velocity there will be more wear of both brushes and segments, and greater consumption of energy due to the increased frictionof the brushes.

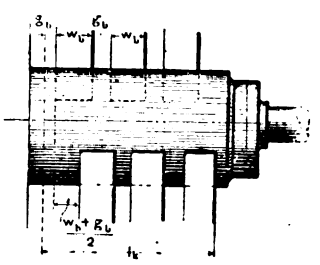

FIG. 39.

The segments are usually made of copper (cast, rolled, or forged), phosphor bronze, or gunmetal, sometimes brass, and even iron being used; the materials for the substructure are phosphor bronze, brass, or cast iron.

From all this it will be obvious that a general formula for the diameter of the commutator cannot be established, and that, on the contrary, this dimension has to be properly chosen in every case with reference to the armature diameter to the design of the commutator, to the materials employed, to the strength of the substructure, or the thickness of the bar respectively, and, finally, with reference to the wear of the segments.

The commutator diameter being decided upon, the size of the brushes can now be calculated, as shown in Section 29, and from this the length of the commutator can be found.

In order to prevent annular grooves being cut around the commutator, the brushes ought to be so adjusted that the gaps between those in one set do not come opposite the gaps in the other set. Denoting, Fig. 39, the width of each brush by w_b, their number per set by n_b, and the gap between them by g_b, we consequently obtain the total length of the commutator brush surface from:

$$l_k = (n_b + \tfrac{1}{2}) \times (w_b + g_b) \quad . \quad . \quad (71)$$

This length of brush surface should be available even after the commutator has been turned down to its final

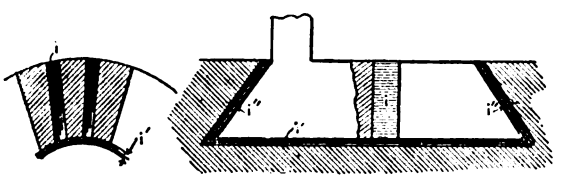

FIG. 40.

diameter. The original diameter must therefore have a somewhat larger contact length. An addition to l_k of from ¼in. to 1in., according to the depth of the bar, is thus necessitated.

(*b*) *Commutator Insulations.*—In a commutator the insulation has to form a part of the general structure, and has to take strain in common with other material used. From its natural cleavage and hardness, therefore, mica is particularly suitable for commutator insulations, and is, in fact, almost exclusively used for this purpose, only asbestos and vulcanised fibre being employed in rare cases.

The thickness of the commutator insulation ought to be proportional to the voltage of the machine, and, for the various positions with reference to the bars, see *i*, *i'*, *i''* (Fig. 40), should be selected within the following limits.

TABLE XXXIV.—Commutator Insulations for Various Voltages.

—	Up to 300 volts.	400 to 750 volts.	800 to 3,000 volts.
Side insulation (*i*) ...	·020″ to ·030″	·030″ to ·040″	·040″ to ·060″
Bottom insulation (*i'*)	3/64 ,, 1/32	1/32 ,, 1/16	1/32 ,, 1/16
End insulation (*i''*) ...	1/16 ,, 3/32	3/32 ,, 1/8	1/8 ,, 1/16

29. *Brushes and Current Leads*—(*a*) *Brushes.*—The best breadth of the brush contact surface, with reference to the prevention of excesssive sparking at the commutator, is that equal to the width of one commutator segment, Fig. 41. If, however, this would make the commutator too long, two bars may be covered by the brush, as in Fig. 42.

In the former case not more than one armature coil is short-circuited at any time, while in the latter case two coils, at times, are simultaneously short-circuited under each set of brushes.

The circumferential breadth of the brush contact may accordingly be expressed by

$$b_k = \frac{d_k \times \pi}{n} - i \quad . \quad . \quad . \quad . \quad (72)$$

or, respectively, by

$$b_k = 2\left(\frac{d_k \times \pi}{n} - i\right) \quad . \quad . \quad . \quad (73)$$

where:

b_k = circumferential breadth of brush contact, in inches;
d_k = diameter of commutator, in inches;
n = number of commutator divisions;
i = thickness of side insulation, in inches (see Table XXXIV.).

For copper brushes the result obtained by (73) should be the maximum breadth employed; for carbon brushes, however, where the coils are short-circuited through the comparatively high resistance of the carbon b_k may be chosen so as to cover three bars of the commutator.

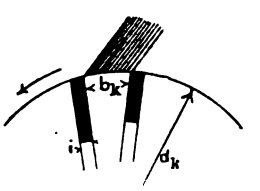

FIG. 41.

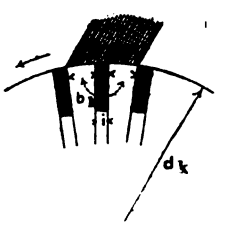

FIG. 42.

Having decided upon b_k by either one of the above formulæ (72) or (73) respectively, or having selected an intermediate value, the width of the contact area, and subsequently the width of the brushes, can be found for a given current output of the dynamo by providing contact area in proportion to the current intensity. In order to keep the brushes at a moderate temperature, and the "loss of commutation" within practical limits, the current density of the brush contact should not exceed 150 to 175 amperes per square inch in case of copper brushes (wire, plate, and gauze), and 30 to 35 amperes in case of carbon brushes.

The total axial width of the brush surface can consequently be expressed by

$$w_k = \frac{C}{150 \times b \times b_k} \quad . \quad . \quad . \quad . \quad (74)$$

for copper brushes, and

$$w_k = \frac{C}{30 \times b \times b_k} \quad . \quad . \quad . \quad . \quad (75)$$

for carbon brushes.

w_k = total axial width of brush contact surface, in inches;
C = total current output of dynamo, in amperes;
b = number of pairs of brush sets (usually either $b = 1$, or equal to the number of pairs of poles, $b = P$).

For the purpose of securing a good contact, each contact surface should be subdivided into a set of n_b individual brushes, of a width w_b each, not exceeding 1½in. to 2in. In small machines, where one such brush would suffice, it is good practice to employ two narrow brushes, even as low down as ⅜in. each, in order to facilitate their adjusting or exchanging while machine is running.

(b) Current Leads.—Care must also be exercised in the proportioning of those parts of a dynamo which serve to lead the current collected by the brushes to the external circuit. For if material is wasted in these, the cost of the machine is unnecessarily increased, and if, on the contrary, too little material is used, an appreciable drop in the voltage and undue heating will be the result.

In order to guard the design of such parts, among which may be classed brush-holders, cables, conductor rods, cable

Digitized by Google

lugs, binding posts and switches, the following Table XXXV. has been prepared, which contains practical averages of the current densities to be employed for cross section and contact surface of the various materials used:

TABLE XXXV.—Average Current Densities for Cross-Section and Contact Surface of Various Materials.

—	Material.	Current density.	
		Square mils per ampere.	Amperes per square inch.
Cross-section.	Copper wire	500 to 800	1,200 to 2,000
	Copper rod	800 to 1,200	800 to 1,200
	Copper-wire cable..	600 to 1,000	1,000 to 1,600
	Copper casting.....	1,400 to 2,000	500 to 700
	Brass casting	2,500 to 3,300	300 to 400
Brush contact	Copper brush	5,700 to 6,700	150 to 175
	Carbon brush	28,500 to 33,500	30 to 35
Sliding contact	Copper – copper ...	10,000 to 15,000	67 to 100
	Brass < copper.. brass ..	20,000 to 25,000	40 to 50
Screwed contact	Copper – copper ...	5,000 to 8,000	120 to 200
	Brass < copper.. brass ...	10,000 to 15,000	67 to 100

(To be continued.)

A NEW SAFETY CONNECTOR.

The introduction of electrical heating and cooking apparatus and the rapidly extending use of the same has shown the necessity of improved arrangements for connecting and disconnecting the conducting wires from the utensils while in use. The kettles, saucepans, etc., require frequent cleansing, and the wires would be damaged if not detached.

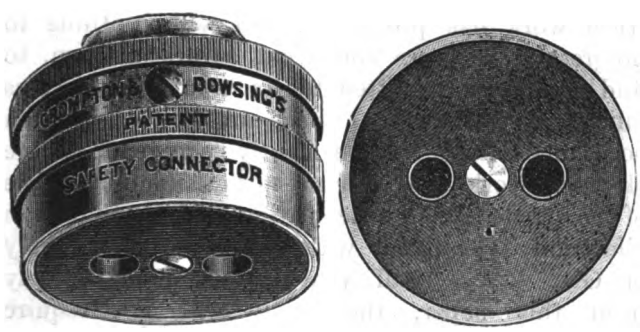

FIG. 1.

The ordinary system of using a plug attached to the wire and inserting it in a socket affixed to the apparatus is not by any means a perfect arrangement, and may prove absolutely dangerous. Protection to some extent may be afforded by a ring of metal or porcelain around the pins, acting as a shield, but, nevertheless, the fact

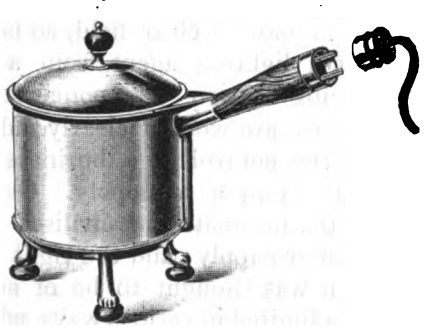

FIG. 2.

remains that there are "live" ends, and a fork or other piece of metal coming in contact with same would cause "fireworks," and possibly send the cook into hysterics. The most serious thing would be the banishing of the electrical cooking apparatus from the household on account of the imaginary danger to life. To prevent all possibility of accidental contact, Messrs. Crompton and Co., Limited, are introducing a patent safety connector in which there are no exposed contacts. The usual arrangements for the connection are entirely reversed, as the pins (or other plug forms of contact) are fixed on the utensil itself, and surrounded with a shield of metal to protect it from mechanical injury. The socket attached to the flexible wire is made with the contact tubes sunk well into the base, and connected up in the ordinary manner. In front of the socket, and covering the entrance to the tubes, is a fibre or porcelain disc, pierced with two holes for the admission of the pins, and free to move on a central screw. A spring fixed underneath tends to keep the disc in such a position that the ends of the tubes are always covered. When the pins are inserted in the holes of the disc, contact is not made until a quarter turn is given to the socket, when the pins are allowed to enter the tubes. The action is extremely simple, and is as natural as turning a key in a lock. Immediately the plug is pulled off, the shield springs round, covering the holes and automatically protecting them. The working parts of the safety connector are enclosed in a nickel-plated case, and two milled rings give plenty of grip power. Fig. 1 is a general view of the safety connector, and Fig. 2 shows the method of using. It will be noted that the connections are brought up to the handle. This prevents the contacts becoming wet and greasy when the utensils are in use, and there is less danger of damage in the cleaning.

The new safety connector can be applied to electric light standards, or, indeed, to any kind of portable fitting, and the necessity of keeping the wire attached is obviated. For floor sockets the safety connector is of considerable value, as the loose blocks or plugs necessitated by the ordinary system are dispensed with when the socket is not in use.

Messrs. Crompton and Co., Limited, are adapting the principle of the safety connector to high-tension switches, terminals, and connections, which will be automatically protected, thereby entirely preventing accidental contact, and consequent injury or loss of life.

HOWARD'S GRAPHIC WIRING TABLE.

We have received from Messrs. W. T. Glover and Co., 39, Victoria-street, Westminster, and Salford, Manchester, a graphic wiring table which has been drawn up by Mr. A. H. Howard, and which possesses some novel features. The dimensions of copper wires and cables are shown in both decimals of an inch and in metric measurements, and the equivalent sizes in solid and stranded wires, the fall of potential, the rise of temperature with given amounts of current, and other necessary information are given. The arrangement is clear and simple, and electric light engineers can at once see the best form of mains and conductors for employment on the work in hand, without resorting to laborious calculations. The various wires and cables are arranged above one another in vertical columns according to their area, ranging from ·001in. to 1 square inch. Thus, all equivalent areas are shown in the same horizontal lines, while diagonal lines give the fall of potential per 100 yards upon any sized conductor with any current from 1 to 1,000 amperes. A series of curves, printed in red, shows approximately the temperature of any conductor with any given current. These curves are based upon experiments in the Edison laboratory made for the purpose of ascertaining the rise in temperature of insulated wires enclosed in wooden casing.

A special feature of the table is the fact that the divisions are drawn at distances proportional to the logarithms of the areas, instead of being directly proportionate to the areas. The diagonal lines showing the fall of potential are thus made parallel instead of radial, with the result that all parts of the table are equally easy to decipher; and a much larger range of sizes is shown in the space than would otherwise be the case.

The resistances of the several conductors are given, in separate columns, at per 1,000 yards and per mile. The weight per mile is also shown.

Directions are given for using the table, which is drawn upon a fairly large scale, and is so arranged as to admit of additional lines being inserted to embody any data that may be useful in particular cases, such as the resistance, etc., of iron, platinum, or other metals which are used in electrical work.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIII. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

AS OTHERS SEE US.

It is a great mistake to think criticism, even when it is seen to be biassed, is valueless. We have often noticed that the very best way to see into the faults of any special apparatus is to talk with a rival inventor of such apparatus. He is profuse in his explanations, showing every faulty point in everything that has preceded his design, ignoring every good point in what has gone before, but restricting his explanation of his own work to the praising of the manner in which he has avoided all these faults. Chats with two rival inventors give an almost infinite source of amusement if the listener can manage to remain in a perfectly negative condition of mind. Human nature is almost always too strong for inventors; they can seldom see any good outside their own doings. But then they are real men, they are so enamoured of their own work that they really believe in what they say. We cannot always say the same of the advocate, and thus it was with some interest that we read a paper by Mr. N. H. Humphreys in our contemporary the *Journal of Gas Lighting*. This paper has systematically belittled electric lighting. It is hardly ever, or never, fair in the selections of work it criticises, and it looks upon everything electrical with prejudice. Well, notwithstanding all its complaints, notwithstanding its prophecies, electrical work has progressed and will continue to progress. We were somewhat surprised, then, to find an article admitted to its columns of a less bilious character than usual—an article in which occasional efforts have evidently been made to see electrical work in a tolerant spirit. The full title of the article is "The Regulations for the Supply of Electricity Compared with those for the Supply of Gas." We shall venture to quote largely from this paper, though it will not require many words to show why its conclusions are erroneous. The author puts the position of gas as regards legislative enactment very clearly as follows:

"The various enactments by which the supply of gas to the public is controlled and regulated were drafted at a time when the suppliers of gas were supposed to have a clear field, so far as the distribution of a lighting agent from a manufacturing or producing station was concerned. The terms in which they are worded clearly indicate that they aimed at the control of a business that was to a very great extent a monopoly. Gas was regarded as one of the necessities of civilised life—something like the water supply; and the right to cut off or discontinue it was thought to be of such importance that it was limited in various ways, while at the same time penalties were introduced for deficiencies either in the quantity or the quality of the supply. The value of the monopoly represented by the right to supply gas was always heavily laboured by the representatives of the public, whenever additional or extended powers were sought. It is relied upon as a valuable weapon at all meetings of the 'gas consumers' indignation' kind, and it has also been brought out as one of the reasons why the gas supply should be in the hands of the local authorities."

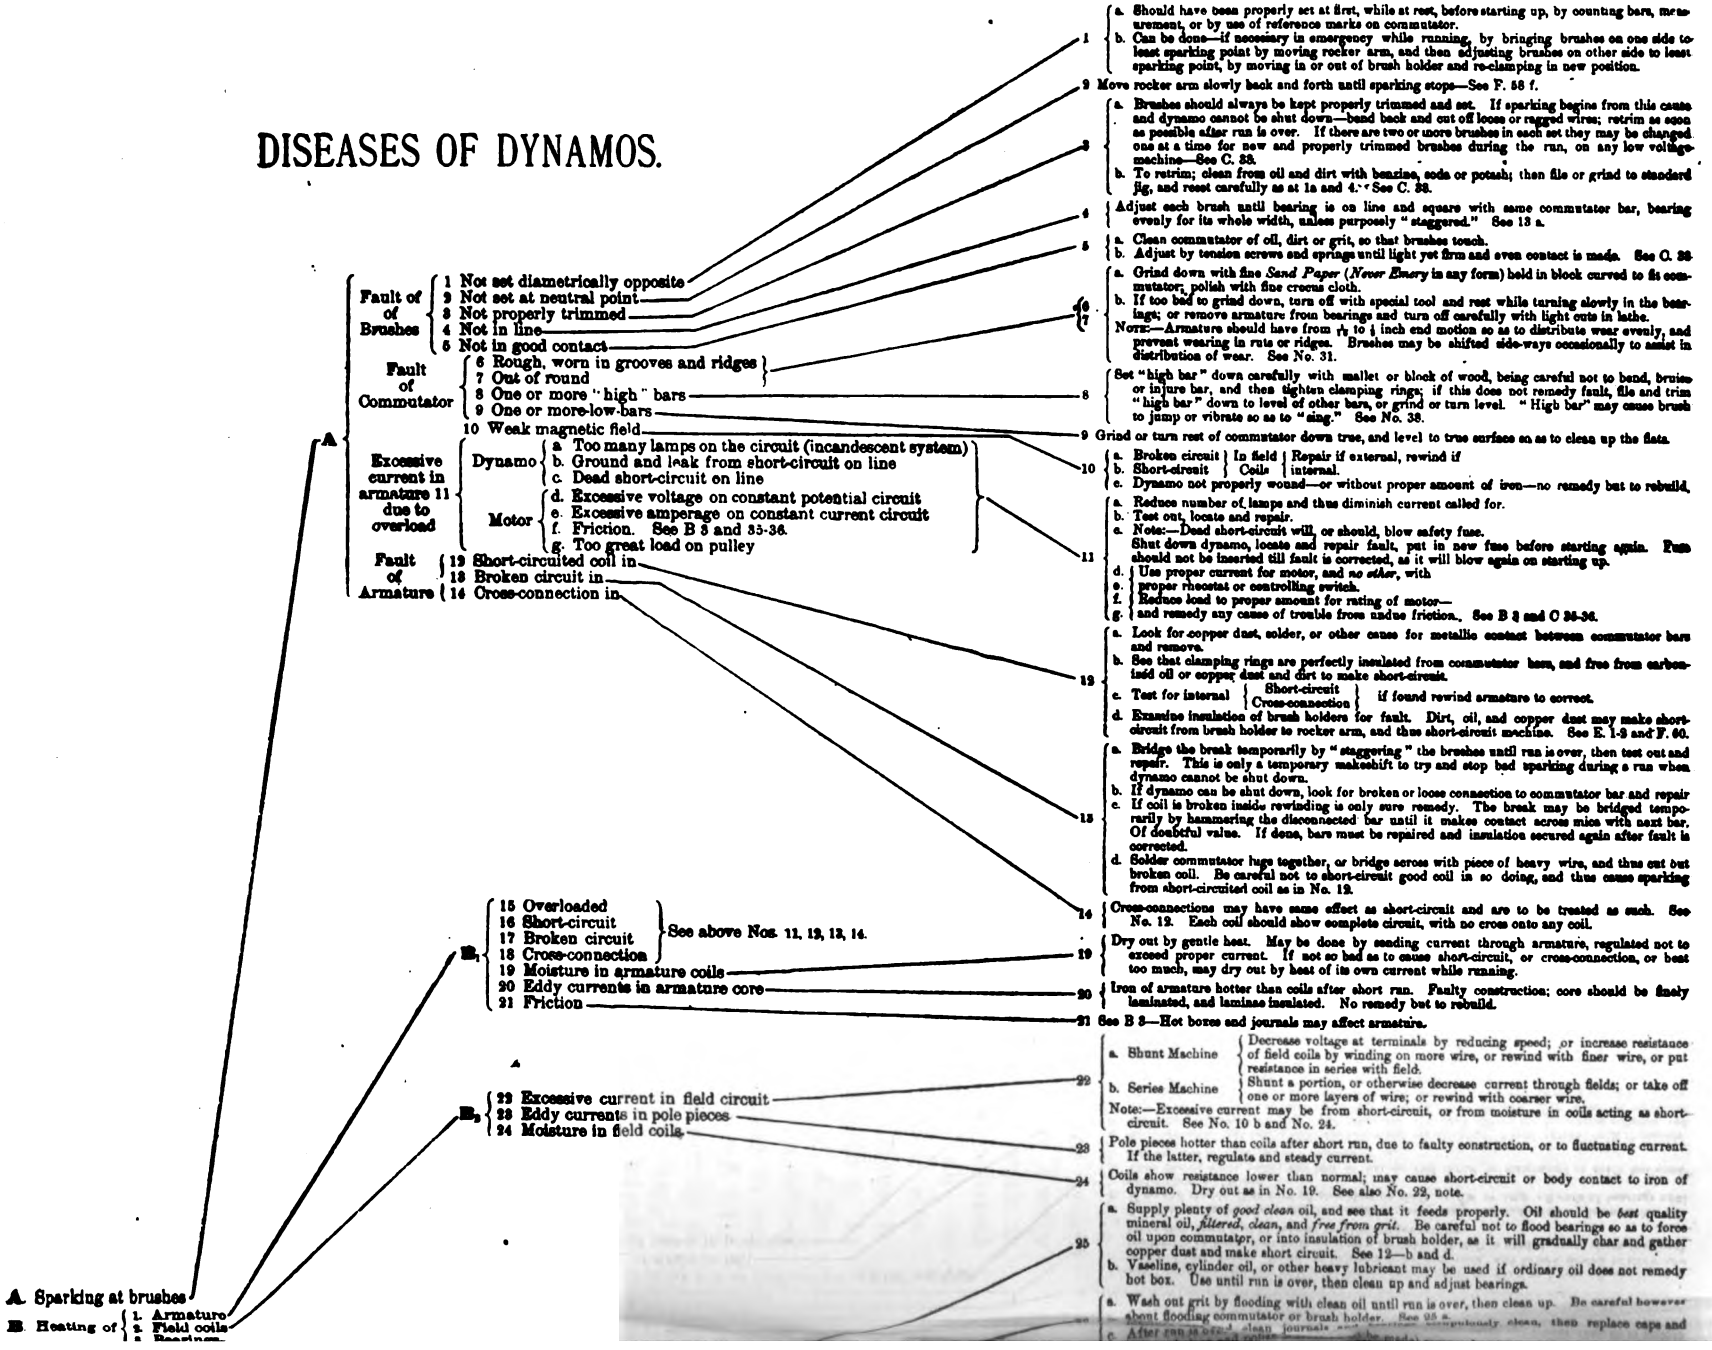
DISEASES OF DYNAMOS.



A. Sparking at brushes
B. Heating of 1. Armature 2. Field coils
Fault of Brushes
1 Not set diametrically opposite
2 Not set at neutral point
3 Not properly trimmed
4 Not in line
5 Not in good contact
Fault of Commutator
6 Rough, worn in grooves and ridges
7 Out of round
8 One or more "high" bars
9 One or more low bars
10 Weak magnetic field
Excessive current in armature due to overload 11
Dynamo
a Too many lamps on the circuit (incandescent system)
b. Ground and leak from short-circuit on line
c. Dead short-circuit on line
Motor
d. Excessive voltage on constant potential circuit
e. Excessive amperage on constant current circuit
f. Friction. See B 3 and 35-36.
g. Too great load on pulley
Fault of Armature
12 Short-circuited coil in
13 Broken circuit in
14 Cross-connection in
B1
15 Overloaded
16 Short-circuit
17 Broken circuit
18 Cross-connection
See above Nos. 11, 12, 13, 14.
19 Moisture in armature coils
20 Eddy currents in armature core
21 Friction
B2
22 Excessive current in field circuit
23 Eddy currents in pole pieces
24 Moisture in field coils
1 a. Should have been properly set at first, while at rest, before starting up, by counting bars, measurement, or by use of reference marks on commutator.
b. Can be done—if necessary in emergency while running, by bringing brushes on one side to least sparking point by moving rocker arm, and then adjusting brushes on other side to least sparking point, by moving in or out of brush holder and re-clamping in new position.
2 Move rocker arm slowly back and forth until sparking stops—See F. 58 f.
3 a. Brushes should always be kept properly trimmed and set. If sparking begins from this cause and dynamo cannot be shut down—bend back and cut off loose or ragged wires; retrim as soon as possible after run is over. If there are two or more brushes in each set they may be changed one at a time for new and properly trimmed brushes during the run, on any low voltage machine—See C. 33.
b. To retrim; clean from oil and dirt with benzine, soda or potash; then file or grind to standard jig, and reset carefully as at 1a and 4. See C. 33.
4 Adjust each brush until bearing is on line and square with same commutator bar, bearing evenly for its whole width, unless purposely "staggered." See 13 a.
5 a. Clean commutator of oil, dirt or grit, so that brushes touch.
b. Adjust by tension screws and springs until light yet firm and even contact is made. See C. 33
6 7 a. Grind down with fine Sand Paper (Never Emery in any form) held in block curved to fit commutator; polish with fine crocus cloth.
b. If too bad to grind down, turn off with special tool and rest while turning slowly in the bearings; or remove armature from bearings and turn off carefully with light cuts in lathe.
Note:—Armature should have from 1/8 to 1/4 inch end motion so as to distribute wear evenly, and prevent wearing in ruts or ridges. Brushes may be shifted side-ways occasionally to assist in distribution of wear. See No. 31.
8 Set "high bar" down carefully with mallet or block of wood, being careful not to bend, bruise or injure bar, and then tighten clamping rings; if this does not remedy fault, file and trim "high bar" down to level of other bars, or grind or turn level. "High bar" may cause brush to jump or vibrate so as to "sing." See No. 38.
9 Grind or turn rest of commutator down true, and level to true surface so as to clean up the flats.
10 a. Broken circuit / b. Short-circuit — In field: Repair if external, rewind if; Coils: internal.
c. Dynamo not properly wound—or without proper amount of iron—no remedy but to rebuild.
11 a. Reduce number of lamps and thus diminish current called for.
b. Test out, locate and repair.
c. Note:—Dead short-circuit will, or should, blow safety fuse. Shut down dynamo, locate and repair fault, put in new fuse before starting again. Fuse should not be inserted till fault is corrected, as it will blow again on starting up.
d. e. f. g. Use proper current for motor, and no other, with proper rheostat or controlling switch. Reduce load to proper amount for rating of motor— and remedy any cause of trouble from undue friction. See B 3 and C 35-36.
12 a. Look for copper dust, solder, or other cause for metallic contact between commutator bars and remove.
b. See that clamping rings are perfectly insulated from commutator bars, and free from carbonized oil or copper dust and dirt to make short-circuit.
c. Test for internal: Short-circuit / Cross-connection — if found rewind armature to correct.
d. Examine insulation of brush holders for fault. Dirt, oil, and copper dust may make short-circuit from brush holder to rocker arm, and thus short-circuit machine. See E. 1-3 and F. 60.
13 a. Bridge the break temporarily by "staggering" the brushes until run is over, then test out and repair. This is only a temporary makeshift to try and stop bad sparking during a run when dynamo cannot be shut down.
b. If dynamo can be shut down, look for broken or loose connection to commutator bar and repair
c. If coil is broken inside rewinding is only sure remedy. The break may be bridged temporarily by hammering the disconnected bar until it makes contact across mica with next bar. Of doubtful value. If done, bars must be repaired and insulation secured again after fault is corrected.
d. Solder commutator bars together, or bridge across with piece of heavy wire, and thus cut out broken coil. Be careful not to short-circuit good coil in so doing, and thus cause sparking from short-circuited coil as in No. 12.
14 Cross-connections may have same effect as short-circuit and are to be treated as such. See No. 12. Each coil should show complete circuit, with no cross onto any coil.
19 Dry out by gentle heat. May be done by sending current through armature, regulated not to exceed proper current. If not so bad as to cause short-circuit, or cross-connection, or heat too much, may dry out by heat of its own current while running.
20 Iron of armature hotter than coils after short run. Faulty construction; core should be finely laminated, and laminae insulated. No remedy but to rebuild.
21 See B 3—Hot boxes and journals may affect armature.
22 a. Shunt Machine: Decrease voltage at terminals by reducing speed; or increase resistance of field coils by winding on more wire, or rewind with finer wire, or put resistance in series with field.
b. Series Machine: Shunt a portion, or otherwise decrease current through fields; or take off one or more layers of wire; or rewind with coarser wire.
Note:—Excessive current may be from short-circuit, or from moisture in coils acting as short-circuit. See No. 10 b and No. 24.
23 Pole pieces hotter than coils after short run, due to faulty construction, or to fluctuating current. If the latter, regulate and steady current.
24 Coils show resistance lower than normal; may cause short-circuit or body contact to iron of dynamo. Dry out as in No. 19. See also No. 22, note.
25 a. Supply plenty of good clean oil, and see that it feeds properly. Oil should be best quality mineral oil, filtered, clean, and free from grit. Be careful not to flood bearings so as to force oil upon commutator, or into insulation of brush holder, as it will gradually char and gather copper dust and make short circuit. See 12—b and d.
b. Vaseline, cylinder oil, or other heavy lubricant may be used if ordinary oil does not remedy hot box. Use until run is over, then clean up and adjust bearings.
a. Wash out grit by flooding with clean oil until run is over, then clean up. Be careful however about flooding commutator or brush holder. See 25 a.
c. After can be sure journals are thoroughly clean, then replace caps and

53 Circuit open { a. Safety fuse melted / b. Broken wire or connections / c. Brushes not in contact / d. Switch open / e. Current fails or is shut off from station }
54 Complete short-circuit of field
55 " " " " armature
56 " " " " switch

E4
57 Wrong connections within motor.

58 Reversed residual Magnetism { a. Reversed current through field coils / b Reversed connections / c. Earths magnetism / d. Proximity of another dynamo / f. Brushes not in right position. See No. 31-2-5 }
59 Too weak residual magnetism
60 Short-circuit in machine. See Nos. 12 and 54, 55, 56
61 Short-circuit in external circuit

F.
62 Field coils opposed to each other
63 Open circuit { a. Broken wire / b. Faulty connections / c. Brushes not in contact. See No. 5 / d. Safety fuse melted or broken. See No. 53 a. / e. Switch open. See 53 d. / f. External circuit open }
64 Too great load on dynamo
65 Too much resistance in field regulator

---

28 { Remove some of cap, put in packing to bring bearing and easy rotation by hand. / b. Turn down, smooth and repolish journal, or ream or scrape bearings to proper fit.

29 Bend or turn true by careful springing or turning in lathe. Probably new shaft will be needed.

30 { Loosen foot of bearings and shift until armature turns freely by hand with belt off, and is yet in centre of polar space. Ream out bolt and dowel pin holes, and fit new dowels to allow new position to be kept when bolts are drawn up tight. If shift is needed *up* or *down* then pack up or trim down foot of bearing to allow proper setting.

31 { a. See that foundation is level and that armature moves freely with end motion—See note No. 67. / b. If no end motion, then turn off shoulders on shaft, or file or trim off ends of bearings until end motion is obtained. / c. Then line up shaft, pulley and belt, so that no end thrust is maintained on shaft, but armature has free end play while in motion.

32 { a. Reduce load so that belt may be slackened and yet not slip. Avoid vertical belts if possible. / b. Use larger pulleys, wider and longer belts, run with slack side on top to increase adhesion and pull off belt, without excessive tightening, so as to drive full load. Belt should be tightened just enough to drive full load smoothly, without any vibration and flapping of belt. Vibration and flapping of belt will cause lamps to wink.

33 { a. Bearing may be worn out, letting armature move out of centre, and need replacing. See No. 36. / b. Centre armature in polar space and adjust bearings to new position. See No. 30. / c. File out polar space to give equal clearance all around. / d. Spring pole away from armature and secure in place. This will be a very difficult, if not impossible job, in large and rigid machines.

34 { Faulty construction. Armature and pulley should have been properly balanced when first made. May be helped somewhat by careful balancing on knife edges and adjusting.

35 { a. Bend or press down and secure any projecting wires, and secure strongly with proper tie bands of wire. / b. File out pole pieces where armature strikes. See Nos. 30-33 for possible remedies.

36 See Nos. 30-31 bearings may be worn out and *too loose*, and therefore rattle. New bearings needed.

37 { Tighten up all screws, bolts and connections to firm bearing, and *keep them so* by daily attention. The jar and tremor of running dynamo tends to work screwed connections loose when not held by check nuts.

38 { a. Apply a *little mineral* oil, or better yet vaseline, or hold piece of stearic acid (adamantine) candle to commutator and then wipe off. Just a *faint trace* of oil or grease should be all that is required. / b. Lengthen or shorten brushes in holder, until firm smooth and yet gentle pressure is maintained free from any hum or vibration. See Nos. 3, 6, 7, 8, 9 and 31.

39 Use endless belt. If laced belt must be used have *square* joints properly laced.

40 Tighten belt, or reduce load. See 32.

41 { a. Slope ends of pole pieces so that armature teeth do not pass edges all at once. / b. Decrease magnetism of field, or increase magnetic capacity of teeth.

42 { Adjust governor of engine to proper regulation if possible. If not, get a better engine. Engine should regulate closely, with proper steam supply, from "no load" to "full load."

43 { a. Series motor on constant current circuit { 1. Put in a shunt and regulate until proper current for load is obtained. / 2. Use proper regulator or governor to control magnetism of field for varying load. } / b. Series motor on constant potential circuit { a. Put in resistance and cut down current. / b. Use proper regulator on controlling switch. / c. Change to automatic speed regulating motor. }

44 { a. Adjust regulator to control speed. / b. Use current of proper voltage and no other, with proper rheostat. / c. Get a better motor—one that is properly built and designed for the work.

45 See 42

46 Overloaded. See A 11

47 { Open switch, hunt out trouble and remove. Keep switch open, and arm of rheostat to position "off" while locating and repairing fault; then close switch and shift arm gradually to position "on" to see if everything is correct. With series motor no great harm will result from motor stopping or failing to start; Shunt motor on C. P. circuit, armature may and probably will burn out, or fuse blow.

48 See No. 35

49 See B 3

50 See No. 10

51 See 11 f and g

52 See B 3, 25 to 33

53 { a. Open switch, hunt out and repair trouble then put in fuse. See note to 11 C. / b. Open switch, hunt for and repair trouble. See No. 13. / c. Open switch to repair fault. See No. 5. / d. Remedy obvious. Also see that switch is in proper order to make proper connection. / e. Open switch, return starting lever to position "off." Wait for current testing from time to time by closing switch and moving starting lever to close circuit.

54 { Test for, and repair if possible. Look to insulation of binding posts and brush holders. Poor insulation, or dirt, oil and copper dust make short-circuit. See No. 12.

55 See 54

56 See 54

57 { Connect up properly, referring to proper diagram. If proper diagram is not to be had try reversing the connection to brush holders. Other changes may be made until proper connections are found for rotation desired, then connect up permanently.

58a, 58d, 58c { Send current from another machine, or from battery, through field coils in proper direction to correct fault. Polarity to be tested by compass needle. If connections or windings are not known, try one way and test; if not correct, reverse connections try again and test.

58b { Connect up properly for rotation desired, referring to proper diagram of connections. See that connections for series coils (in Compound Dynamos) are properly made, as well as those for shunt coils. See 57

58f { Shift brushes until evidence of improvement is given. Position of brushes for best generating power should be clearly indicated and is generally at or near neutral points. See Nos. 1, 2 and 5.

59 See 58

60 See Nos. 12 and 54, 55, 56

61 { Lamp socket, or other part of line short-circuited or grounded may prevent building up of shunt or compound machines. Search out and remedy before closing switch. See also 54, 55, 56.

62 { Reverse connections of one of field coils and test; compass should show opposite polarity of pole pieces. If after such trial dynamo does not build up try 58 a.c.d. If current does not then come up in proper direction, cross field connections, or recharge in opposite direction. See 55.

63 { a. Search out and repair. See No. 13. / b. See No. 37. / c. See No. 5. / d. See No. 53 a. / e. See No. 53 d. / f. Test out and repair, *with dynamo switch open* until repairs are completed.

64 { Reduce load to pilot lamp alone (Shunt or Compound Incandescent Machine.) After dynamo comes up to full voltage, as shown by pilot lamp, or voltmeter, close the other circuit in succession and watch and regulate voltage. See 11 a and 65.

65 { Gradually turn regulating switch to cut out resistance and watch pilot lamp. When dynamo comes up regulate, &c.

Note:

Never use ice or water to cool off bearings, as it may get into armature and ruin it, unless it has been made water-proof as in some cases of street-car motors.

Never shut down because of hot box until remedies 32, 28, 26 and 25 have been tried and proved useless. If absolutely necessary to shut down, get belt off as soon as possible, do not allow shaft to "stick" in stopping, get boxes or bearings out and cool off naturally as soon as possible and not in water as this may ruin them, then scrape, fit, polish, clean shaft and test for free turning by hand before belting up and starting again.

Cleanliness about Dynamo or Motor is imperative; dirt, oil, copper dust may prove source of great annoyance or damage. Small tools, bolts or pieces of iron must be kept away from dynamo as they may be drawn into, or fall upon armature and ruin it.

A Good Rule. Never allow loose articles of any kind to be placed upon any portion of dynamo. Brass or copper oil cans are best to use as they are non-magnetizable.

All connections must be large clean and firm. Look over and tighten loose connections, screws or bolts daily.

Always keep copper brushes raised from commutator when dynamo is at rest. Poor cheap oil is poor economy; use none but the best of mineral oils. All new oil should always be filtered before using.

Oil from self-oiling bearing should be filtered before being used again.

Keep cotton waste off the commutator. Use canvas or cloth to wipe with.

A piece of pine makes a good burnisher to use on commutator to keep it clean and smooth.

Mr. Humphreys cannot see that anything in the nature of a "necessity" ought never to be a monopoly, except that the monopoly be in the hands of the people themselves. Light is a necessity, and to tax the masses for the pecuniary benefit of the few, as has been done in the case of gas, is a monstrous mistake. Can Mr. Humphreys point to any other industrial manufacturing operation where there is free and open competition with capital so remunerative? We are not of those who would generally restrict the profits of the capitalist. We do take exception, however, in sweating the population for the benefit of the few when air, light, or water is in question. These necessities should be given to the people at the lowest possible cost, and that can only be done when the necessary arrangements are conducted properly by the people themselves. When it became certain that electricity must become a competitor with gas for lighting purposes, those interested in the general welfare of the country, though hardly pressed by the parties interested in the development of electrical work, refused to give monopolist facilities. They had been given to gas, and this was seen to be a mistake. So great was this feeling that in the earlier electrical enactments too little freedom was given, and there was a general outcry that development was cramped. We only agree partially with those who condemn this early legislative work. Mr. Humphreys deals lengthily with the question that a would-be customer can demand connection under certain circumstances both with gas and electric light mains, and that the terms which can be imposed upon small consumers are better for electricity than for gas. He also tells us that he has never heard that the gas managers impose even the terms allowed, while assuming that the electric light managers do so. Has he any proof of this? Here is what he says:

"If the matter was thoroughly enquired into, it would be found that the absence of anything in the way of a minimum charge for gas entails a considerable loss on the suppliers. The question has never been raised yet, because no urgent necessity has arisen for doing so; nor have I heard of a case where a guarantee of minimum consumption was demanded, except in connection with special circumstances, such as extending the service or main beyond the prescribed limit.

"The electricians have secured a very substantial protection against losses of this sort by the insertion in their provisional orders of a clause which runs something like this: 'They shall be entitled to charge at the following rates per quarter: for any amount up to twenty units, 13s. 4d.; and for each unit over twenty units, 8d.' The price named, of course, varies according to each case; but the principle is that a consumer must pay for twenty units each quarter, whether he uses it or not. Even during the summer quarter, not less than this amount must be paid for. Applying this rule to the case of gas, twenty units may be taken as representing two thousand cubic feet. Every gas company has five, ten, or even a larger percentage of customers on its books who do not pay for over one thousand cubic feet in the summer quarters at any rate. The right to charge a minimum of two thousand cubic feet per quarter, would mean an increase of income sufficient to warrant a reduction in price; and gas companies are placed at an unfair disadvantage, if such a privilege is allowed to their competitors but denied to themselves."

The right to charge and the charging are two different things. We have experience of this difference in another matter. Certain men paid about ten thousand pounds for certain water rights. When the money was gone beyond recall they found they had the rights still, but not the water. We do not question the right of electrical engineers to charge, but we question their actually doing so. Other points of Mr. Humphreys are made in the following paragraphs, only one or two, however, of which we shall notice:

"A point in connection with the charge for public lighting may next receive attention. The 1871 Act provides that the price of gas supplied to public lamps may be settled by agreement, or, in case of difference, by arbitration; regard being had to the circumstances of the case and the price charged to private consumers. So far, this is quite as much as could be expected; but in many private Acts it has been over-ridden by a condition, inserted under pressure at the demand of the local authority, to the effect that public lamps should be supplied at the lowest price charged to any consumer. Such a stipulation was brought forward and approved in the spirit already noticed—that of regulating a monopoly—and evidently with regard to the probability that the whole of the streets and public spaces would be lighted by gas, causing the aggregate consumption to be larger than that of any private customer. But it is a strong point with the electric lighting companies to secure, not the whole, but a selection, including the cream, of the public lighting, and the same authorities who forced the above obligation on gas companies are perfectly willing to favour electricity in this respect. If their endeavours are attended with success, the gas company lose all the high-power lamps, and a large proportion of the remainder; being left with a comparatively small and widely-distributed consumption in the by-lanes and outskirts. The loss of a privilege should, in common fairness, carry with it the removing of an obligation bearing upon that privilege; and the hardship involved in the obligation to supply the leavings of their competitors at the old rate, is too obvious to need further amplification.

"We have, however, not yet exhausted the advantages afforded to electricity as compared with gas. The gas companies' powers are usually supposed to cease at the meter, and the consumer can do as he pleases beyond it. If he chooses to vary the pressure in the mains in the vicinity, by suddenly and frequently altering the rate of his consumption, the company have no remedy. He may put one hundred lights on, or cut them off without notice; and I have heard it alleged by a solicitor that the gas company have no right to ask how many lights are in use. The same

Digitized by Google

gentleman, by the way, has since proved perfectly willing to allow an electric lighting company the right to inspect the whole of his wires and lights as often as they choose. But Clause 21 of the 1871 Act seems to give power to enter the consumer's premises and inspect the fittings at all reasonable times. This clause may be useful in case of a disputed account, or where a meter has failed to register; but it is not often used, and many undertakings have preferred to drop it entirely for the sake of working peaceably with their customers. This power to inspect, whatever it may be worth, evidently has reference only to questions relating to the quantity of gas consumed, and the charge for the same. There is no right to raise a question as to the suitability or efficiency of any appliance in use.

"The following extracts from electric lighting provisional orders, however, point to a different footing: 'Provided also that if the owner or occupier . . . uses any form of lamp or burner, or uses the energy supplied to him . . . so as to unduly or improperly interfere with the efficient supply of energy to any other body or person, . . . the undertakers may discontinue to supply energy to such premises. The undertakers shall not be required to supply any premises unless they are reasonably satisfied that the electric fittings are in good order, and not calculated to affect injuriously the use of energy.' These clauses admit a large extent of control right up to the point of consumption. They are further of use in aiding the electric company to control the supply of fittings, which is a very important branch of the business, and in many cases furnishes (at present, at any rate) the chief part of the profits. Persons will naturally hesitate about placing an order for electric fittings with a local tradesman when there is a risk that the company may condemn the whole. The important feature, however, is that whereas gas companies are helpless in the matter of controlling wasteful or careless usage, the suppliers of electricity have very wisely secured considerable powers in this direction."

When legislation was considered for gas concerns, such things as gas-engines were unknown, and the fluctuations of neighbouring lights caused by their extensive use not therefore considered. But they came up, and these effects had to be considered. Electricians tried to provide against widespread complaints because of fluctuations in neighbouring lights through the action of one consumer. We could write a long article as to the remarks on inspection and control of fittings, but leave Mr. Humphreys's words without further comment than to say there is a difference between gas and electricity, and a difference between their fittings. The one set of fittings may be suitable within wide limits, the other not. We take it that this inspection and control is vastly in favour of the consumer, and we think all electrical engineers also take this view.

DISEASES OF DYNAMOS.

Lieutenant C. D. Parkhurst has contributed to the *Transactions* of the American Institute of Electrical Engineers a special supplement on the diseases of dynamos. We have reproduced this supplement as we think it ought to be carefully studied by every man who is engaged in central-station work, or, in fact, in any way engaged in the construction or use of dynamos. The amount of labour involved in the compilation of a sheet of this kind is immense, and Lieutenant Parkhurst is to be congratulated upon the exhaustive details he has given.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTROMOTIVE FORCE.

SIR,—"Student" gives, on p. 304, a number of definitions of this term, which exhibit some difference as to its relation to the other term, "potential difference," which (like "voltage" and electric "pressure") is commonly regarded as a synonym. In the gradual differentiation of technical terms there is sure to be some little confusion, especially where no important distinction exists.

There is, however, a real distinction in this case, involving a relation of cause and effect. Had "Student" consulted my book, "Electricity, Its Theory, Sources, and Applications," he would have found, p. 106, a definition which embodies that distinction: "Electromotive force, shortly written E.M.F., and symbolised by E in formulæ, measures the generative power in terms of potential—that is, of the capacity to generate current, or to overcome resistance." This in relation to batteries. On p. 299 it is said more generally, "Electromotive force is the general name for whatever may be the agency which sets up electric current. Some writers object to the use of the term, which is, however, too useful to be set aside. E.M.F. corresponds to, and is always accompanied by, *potential* in static electricity; hence it is often called *electric pressure*."

This is the very distinction which is implied in your remarks (p. 307). The common sense of the terms shows that E.M.F. applies to the originating cause, the first effect of which, as of all forces, is to set up a pressure, or stress, which then results in the motion which is called current. In a secondary sense the pressure, or potential difference between any two points in a circuit, is also the acting E.M.F. between those points.

We may say that while the *pressure* is a manifestation of energy, and *potential* is an expression of it, E.M.F. is the energy itself. It is the potential energy charged upon a molecular chain of matter, and it is the energy that chain can deliver up as heat or work, under those conditions which constitute an electric circuit. This is put in the form of a law, p. 318 of my "Electricity," "*Wherever there is free energy present* (as heat in thermo-electricity), *or wherever there is potential energy, seeking to become free* (as when chemical affinities can come into play), *in presence of differential molecular structures or conditions, there energy takes the form of electric potential.* The quantity of energy associated with any molecular conditions, or acting in the molecular chain, measures the E.M.F. due to the particular conditions. The generation of E.M.F. in dynamo machines also depends upon the energy applied to moving the wires across a magnetic field, in which they are subjected to molecular stresses."

As to examiners, is not the suggestion on p. 307 somewhat over-cynical? No doubt they are subject to human weaknesses. I should probably regard with more favour a reply in electrolysis based upon molecular theories, in which I believe myself, than one dependent upon the atomic dissociation ideas, which I consider absurd; but still, as would most others, I should certainly consider whether the student had fairly mastered the ideas which it had been his misfortune to be taught.—Yours, etc.,

JOHN T. SPRAGUE.

TURNING DOWN ELECTRIC LIGHTS.

SIR,—I thank you for publishing my letter in your last issue, but not for your *résumé* of the *Birmingham Gazette* article, or for your article thereon. As, however, you have

Digitized by Google

devoted your leader and two columns to "walking into" my patents, I also thank you in anticipation for permitting me to reply in half the space.

As the commercial value of the patents lies in the switch arrangements which switch from parallel to series, or from one series to another, I will deal with them.

Firstly, take the switch which switches from parallel to series. If there are two lights in a bedroom, railway carriage, or elsewhere, my switch, by a single movement of the switch handle lowers both lamps to such a low pitch that one can just see one's way about, and in doing so cuts off from four-fifths to five-sixths of the current, at the same time reducing the cost per hour to something between one-fifth and one-sixth of what it is when not lowered. Here may I point out where an error has crept into your leader—the wiring or existing switches are *not* necessarily altered. The usual double cord from which a 16-c.p. lamp is hung may be cut close to the lamp, and a pair of 8-c.p. lamps, with a switch attached to them, may then be placed in its stead, which switch will either raise, lower, or put the light out; but if it is always left full on, then the usual existing switches at the door act as usual. Permit me also to point out an error in your *résumé* of the *Gazette* article. The cluster of six does not switch from series to parallel. It works this way: when full on it runs in three lots of two series, but when I throw the switch handle over it runs in two lots of three series, and gives a pleasant subdued light suitable for entertaining-rooms, churches, etc. When full on it uses 3½ amperes, and when turned down it uses 1½ amperes, or considerably less than half: this is much pleasanter than turning out above half the lamps and having alternate glares and dark places and strong shadows. In no case do I turn out any of the lamps or bring others (usually out) into play, and in no case do I use a resistance, which is, after all, the same as if a man slowed his engine by putting on the break or having a blow-off cock on his cylinder.—Yours, etc.,

THOMAS BUDWORTH SHARP.

County-chambers, Birmingham, Sept. 18, 1894.

ADVERTISING BY ELECTRICITY.

SIR,—I was surprised to see in a paragraph of a contemporary of yours, commenting on the throwing of advertisements on Nelson's column, etc., in Trafalgar-square, the statement made that it is impossible to decipher any words.

From the notices which have recently appeared in the daily papers, it would seem that a great majority of the public not only see a light, to which they would scarcely object, but can read and recognise well-known advertisements. Being interested in the method of throwing signs to such a distance, through the courtesy of the Electrical Long-Distance Advertising Syndicate, I have attempted to photograph some of them, and I enclose a print of a negative taken a few months ago on an ordinary plate, about 9.40 p.m., giving 10 minutes' exposure with $f/_{16}$ stop, the distance of the screen (St. Martin's Church) from the lantern being 250 yards. Recently a similar apparatus was used at a large *fête* held in the grounds of Mr. Gladstone's residence at Hawarden, and a local photographer succeeded in taking several negatives showing various sentences, which in this case were thrown on the trees in the park.—Yours, etc.,

VERITAS.

CITY AND GUILDS OF LONDON INSTITUTE.

LECTURE III.—THE VOLTAGE REQUIRED TO PRODUCE ANY REQUIRED CURRENT IN A WIRE OF GIVEN RESISTANCE.

(Specially contributed.)

In our previous lectures we have seen:

1. That we must have a difference of electric pressure in order to obtain a current.

2. That the path or circuit of the current must be continuous all round, must return to itself—must, in fact, be closed.

3. That the current in the circuit depends not only on the pressure acting, but also upon the resistance offered by the circuit.

This *resistance*, *current*, and *pressure* are quantities that can be measured, but before carrying out such measurement we have to decide upon units of measurement, just as in measuring lengths we have the "yard" as the unit. This is merely an arbitrary length between two particular points. According to the Act of Parliament the Imperial yard is defined in this way: "That the straight line between the centres of the transverse lines in the two gold plugs in the bronze bar deposited in the office of the Exchequer shall be the genuine standard yard at 62deg. F." The yard may be called a practical unit. If every standard yard was lost, the work of reconstruction would be a little troublesome. In electrical work an effort has been made to obtain units that should not be of so arbitrary a character, and this has led to a double set of units. It is with only one of these sets of units that we need trouble ourselves at present—the practical units. Quite lately the Board of Trade has issued an order referring to these units—to be called standard units—of which I may read the following paragraphs:

"I. *Standard of Electrical Resistance.*—A standard of electrical resistance denominated one ohm being the resistance between the copper terminals of the instrument marked 'Board of Trade Ohm Standard Verified 1894' to the passage of an unvarying electrical current, when the coil of insulated wire forming part of the aforesaid instrument and connected to the aforesaid terminals is in all parts at a temperature of 15·4 C.

"II. *Standard of Electrical Current.*—A standard of electrical current denominated one ampere being the current which is passing in and through the coils of wire forming part of the instrument marked 'Board of Trade Ampere Standard Verified 1894,' when, on reversing the current in the fixed coils, the change in the forces acting upon the suspended coil in its sighted position is exactly balanced by the force exerted by gravity in Westminster upon the iridio-platinum weight marked A, and forming part of the said instrument.

"III. *Standard of Electrical Pressure.*—A standard of electrical pressure denominated one volt being one-hundredth part of the pressure which, when applied between the terminals forming part of the instrument marked 'Board of Trade Volt Standard Verified 1894,' causes that rotation of the suspended portion of the instrument which is exactly measured by the coincidence of the sighting wire with the image of the fiducial mark A before and after application of the pressure, and with that of the fiducial mark B during the application of the pressure, these images being produced by the suspended mirror and observed by means of the eyepiece.

"In the use of the above standards the limits of accuracy attainable are as follows:

"For the ohm, within one-hundredth part of 1 per cent.

"For the ampere, within one-tenth part of 1 per cent.

"For the volt, within one-tenth part of 1 per cent.

"The coils and instruments referred to in this schedule are deposited at the Board of Trade Standardising Laboratory, 8, Richmond-terrace, Whitehall, London."

The *ohm* is the name given to the unit resistance. This standard unit is the equivalent wire resistance to the resistance offered to an unvarying current by a column of mercury at the temperature of melting ice, 14·4521 grammes in mass of a constant cross-sectional area, and of a length of 106·3 centimetres.

The *ampere* is the name given to the unit current, and is that current which, when used to deposit silver from a solution of nitrate of silver under certain conditions, deposits it at the rate of 0·001118 of a gramme per second—that is, 4·0248 grammes per hour. It may be interesting to know a little more about the electrolytic action of the current. This table gives you some information.

One ampere deposits per hour	1·174	grammes	copper.	
,, ,, ,,	4·025	,,	silver.	
,, ,, ,,	2·441	,,	gold.	
,, ,, ,,	1·099	,,	nickel.	

or

1lb. copper is deposited per hour by	386·4	amperes.	
,, silver ,, ,,	162·7	,,	
,, gold ,, ,,	185·8	,,	
,, nickel ,, ,,	412·8	,,	

The *volt* is the name given to the unit pressure, or

Digitized by Google

E.M.F., and is that pressure which if steadily applied to a conductor whose resistance is one ohm will produce a current of one ampere.

The materials which offer least resistance to the current are the metals, hence these are said to be good *conductors*. Certain materials—such as paraffin, glass, dry air, etc.—offer great resistance to the current, and are termed *insulators*. Mr. Cully gives the accompanying table of good and bad conductors:

Good conductors.	Semi-conductors.	Insulators.
Silver	Carbon	Wool.
Copper	Graphite	Silk.
Gold	Acids	Sealing-wax.
Aluminium	Saline solutions	Sulphur.
Zinc	Sea-water	Resin.
Platinum	Melting ice	Guttapercha.
Iron	Pure water	Indiarubber.
Tin	Stone	Shellac.
Lead	Dry ice	Paraffin.
German silver	Dry wood	Vulcanite.
Antimony	Porcelain	Glass.
Mercury	Dry paper	Dry air.

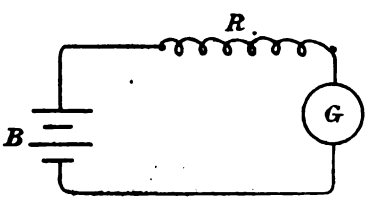

FIG. 1.

Generally, copper is employed for electric conductors. All these wires which I use to make the connections are of copper, though the wires of which these coils are made—which have been carefully made to have resistances of one or more ohms, or parts of an ohm—are some made of German silver and some of platinoid.

I want you now to pay a little closer attention to this circuit. You see it consists of the battery, B, some large connecting wires, a coil of wire which has a large resistance, indicated in the diagram by R, and a galvanometer. The *complete circuit* resistance then includes the resistance of the

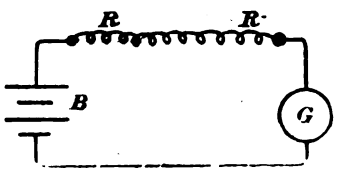

FIG. 2.

liquids and metals of the battery, the resistance of the various connecting wires, of the coil R, and of the galvanometer. The resistance of the battery is generally called the *internal* resistance of the circuit, that of the other parts the *external* resistance. You will see that it is very easy for me to vary the external resistance by putting different connecting wires or coils, while the internal resistance cannot be so varied at will. We shall learn more by-and-by about this internal resistance, and find that when the battery is working there is usually a variation in internal resistance. I am now using one that varies as little as any, and a galvanometer that by direct reading shows the current. The

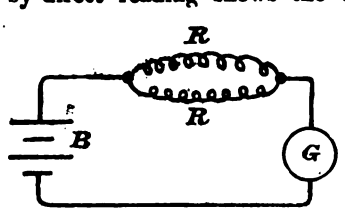

FIG. 3.

internal resistance we will symbolise by *r*, the external by R. The resistance of the coils I am using is very large compared with the other resistances of the circuit.

1. Join up the circuit, as shown in Fig. 1. We get a deflection on the galvanometer, which you see. Call that deflection C.

2. I now join a second coil to the first, as in Fig. 2, and when resistances are joined like this they are said to be in series. By this means I have increased the resistance, and see, at once the current falls to a point showing about half what it was before—that is, now $\frac{C}{2}$. It would be exactly half had the total resistance of the circuit been doubled.

3. Arrange the coils as in Fig. 3—in parallel. Now we see the current, C, is almost doubled.

In each of these experiments we may assume the pressure to have been constant.

We see, then, that lengthening the wire without altering its sectional area increases its resistance — that is, the resistance of conductors increases directly as their length; double the length, and you double the resistance. Our third experiment shows that when the length is unaltered—for the length of wire in each of the coils is the same—and the sectional area is increased, the resistance is decreased; for putting two wires side by side is the same as putting one wire of the original length and double the sectional area. Thus resistance depends upon material employed, upon length of material and sectional area of material.

Current, then, is inversely proportional to resistance; or

Current varies *inversely* as resistance,

which we may symbolise—

$$C \propto \frac{1}{R}.$$

I am now going to modify the three experiments just tried by using another battery to give double the pressure of the former one.

We see that all else, except battery, being as No. 1, we get twice the current we originally obtained.

In the second case we also get twice the original current, and also in the third case.

This shows us that current varies *directly* as pressure, or E M.F., which in symbols we write

$$C \propto E,$$

where E indicates pressure.

Combining the two sets of symbols, we may write

$$C \propto \frac{E}{R},$$

which reads thus:

Current varies *directly* as E.M.F., or pressure, and *inversely* as R (resistance).

In the early part of this century Prof. Ohm proved more than this with steady continuous currents—not only that

$$C \propto \frac{E}{R},$$

but that

$$C = \frac{E}{R};$$

or, expressed numerically in practical units,

$$\text{amperes} = \frac{\text{volts}}{\text{ohms}}.$$

And this connection between current, pressure, and resistance is known as *Ohm's law*.

Now, knowing any two of these quantities, the third can be found by simple arithmetical operations. But before troubling about the arithmetic I want you to look at the subject from any other point. Instead of saying a conductor has a small resistance, we may say it has great conductivity, or a conductor of great resistance has small conductivity. Hence conductivity and resistance are inverse properties. Because of this Mr. Sprague has suggested that we should look upon a conductor as having capacity, rather than as having resistance. Suppose, then, for a moment we consider this suggestion. We might take for a unit the wire that has capacity for one ampere under a pressure of one volt. This wire of unit capacity would have a certain length with a given sectional area. If two wires were used in parallel of this length and sectional area, the capacity would be doubled, and every conductor might thus be looked upon as composed of parallel wires of given capacity. Lengthening a wire would decrease its capacity, increasing its sectional area would increase its capacity. I have merely mentioned this that you may be prepared to find opinions varying as to the best way to treat the subject. At the present time most people are content to use the term "resistance" in the manner I have endeavoured to explain to you.

CITY AND GUILDS EXAMINATION.

(Concluded from page 304.)

SECTION II.—DYNAMOS, MOTORS, ETC.

Answer questions Nos. 2 and 5 of the ordinary grade, and not more than four of the following:

27. A four-pole Gramme armature of a motor is required to give at 400 revolutions a minute a back electromotive force of 100 volts. Flux from each pole-face 3,000,000 magnetic lines. [Neglect resistance and armature reaction.] State the number of armature conductors required and the current through each if the total current is 200 amperes.

28. Illustrate, with sketches, the difference between a wave winding and a lap winding as applied to a four-pole continuous-current armature.

29. What is magnetic slip in a multiphase rotary-field motor? And what is approximately the relation between current, torque, and magnetic slip?

30. State the best relation between armature resistance and armature reaction for shunt motors to run at constant speed under variable load, current being supplied at constant voltage.

31. Give hand sketch illustrating construction of an alternator with fixed armature.

32. What is the usual value of the intensity of the magnetic field in the gap space of ordinary continuous-current dynamos? Also, what determines its variation from one edge to the other of the pole-face?

33. An alternate-current transformer has 200 turns in its secondary winding, the induced electromotive force in which is 102 volts, the frequency being 100 periods per second. Assume that B will not exceed 4,000 lines per square centimetre. What must be the sectional area of the core?

34. What are the essential differences of construction to be found between arc lamps for alternate currents and arc lamps for continuous currents, and what are the reasons for these differences?

35. You have two dynamos of same type and size. Describe the method of testing them for efficiency, in which only the waste power is supplied, and is supplied electrically.

36. What features in the design of a dynamo determine whether it will or will not run without sparking?

SECTION III.—LIGHTING AND POWER.

Answer questions Nos. 4 and 6 of the ordinary grade, and not more than four of the following:

37. Give a diagram showing connections of a switchboard for three alternators intended to work in parallel four feeders and one exciting dynamo.

38. Give sketches of, and briefly describe, any system of bare copper underground conductors.

39. Compare critically the merits, as far as the line is concerned, of the following systems of power transmission by alternating currents—viz.: (*a*) single phase; (*b*) two-phase with three wires; (*c*) two-phase with four wires; (*d*) three-phase.

40. Describe and sketch a lightning-guard for overhead power lines.

41. Explain the interaction of capacity and self-induction on alternating circuits and the troubles it may cause.

42. Compare critically, both as regards capital outlay and working expenses, the distribution within a radius of 1½ miles of continuous currents with that of alternating currents.

43. Explain the various ways in which the term "load-factor" is used.

44. A continuous-current motor is run on a series arc light circuit. Describe a means for keeping its speed constant under varying load.

45. Draw up, briefly, a schedule of rules and conditions to be fulfilled by consumer before you will connect his circuit to the public mains.

46. Illustrate Lord Kelvin's law of economic proportion in cost of lines by an example of continuous-current power transmission; taking the case of a line for delivering 100 h p. at a distance of four miles; maximum voltage, 3,000 volts.

47. Find the stress in a copper wire 160 mils in diameter, weighing 77lb. per 1,000ft., used for a 60-yard span with a sag of 1ft.

48. Sketch the connections of a synchroniser.

SOME NEW RECORDING INSTRUMENTS.

The scope for improvement in electrical recording appliances lies not so much apparently in altogether new methods or principles of action, as in the elaborating of details and constituent parts already well known. By taking any ordinary type of instrument, and paying careful attention to its improvement in every little detail, much better results may be obtained than have been hitherto accepted as sufficient.

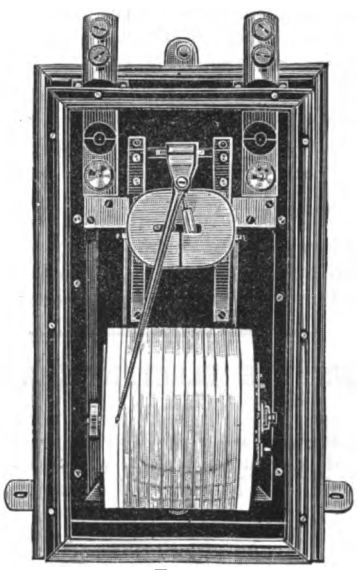

FIG. 1.

In the latest forms of recording voltmeters and ammeters brought out by Messrs. Nalder and Harrison this plan seems to have been largely followed, although at the same time some really novel features are also to be noticed in both these classes of instruments.

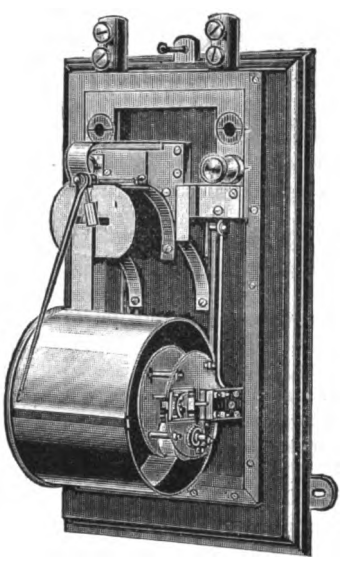

FIG. 2.

The voltmeters, which are intended to register on a circuit with more or less constant E.M.F., are made somewhat after the D'Arsonval type, the magnet being wound in such a manner that it will be saturated when the E.M.F. is about 30 per cent. lower than the voltage of the circuit on which it is intended to register. Thus the hysteresis error is negligible.

The ammeters, on the other hand, are made with a very small amount of iron, which is fixed in the most effective position; they are accordingly well suited for both alternating or direct current circuits. Throughout the whole device the effort has been, of course, to secure a maximum amount of force to move the registering or recording pen

Digitized by Google

(of the usual ink-trough type) with a minimum consumption of electric energy: and these instruments require for their operation less than 10 watts.

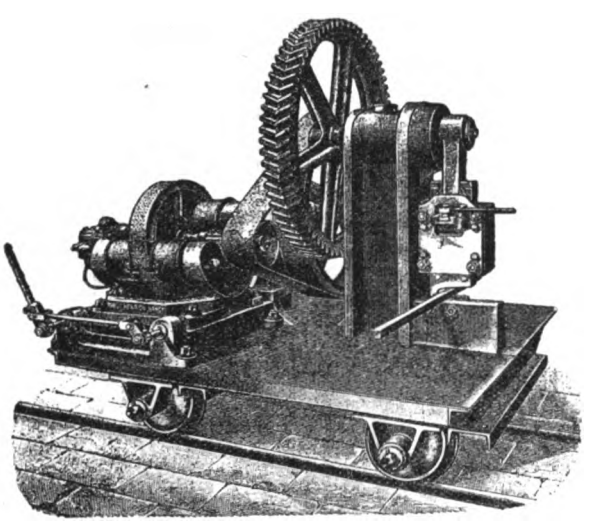
In the ammeters, as above mentioned, a special arrangement of the magnetic field is provided, so as to concentrate force on the movement actuating the recording pen; this is done by shaping the iron in a novel fashion, and by the moving iron on arms attached to the spindle which is on the outside of the coil, thus increasing the force transmitted to the recording pen and obtaining practically equal division on the scale.

With these instruments, the makers state that they have succeeded in reaching such a degree of sensitiveness as to record variations of less than ·3 per cent. In both classes of instrument the controlling force of the index and pen is that of gravity, due to a variable weight, and an additional means of careful adjustment between pen and recording surface is given by pivoting the drum on which the paper is placed with its clockwork motive power. A few turns of a screw with milled head will then give a movement to the drum surface outwards towards the pen, or inwards away from it, and a very delicate adjustment is thus obtained.

We illustrate in Figs. 1 and 2 views of an ammeter with glass front cover and of the same in perspective with cover removed. The voltmeters are somewhat similar, but we hope to give illustrations of these in some future issue, also further details of the results obtained with same.

PORTABLE ELECTRIC SHEARS.

We illustrate herewith a portable electric shears which is being used at the metallurgical works of the Petit-Fils de F. de Wendel, at Hayange, Lorraine. Large bars of



iron have to be cut there, and it is often inconvenient to take them to the shears, so the plan has been adopted to bring the shears to the iron instead. The shears are operated by a Henrion electromotor, which takes 75 amperes and 110 volts, and runs at 800 revolutions per minute. The tool is mounted on wheels, and the same motor can be connected so as to drive the apparatus to the part of the works where it may be required. Current is obtained by means of a trolley from the general installation in the works. The arrangement has resulted in great economies of time and money.

THE ELECTROLYTIC PRODUCTION OF CAUSTIC SODA AND CHLORINE.

On a recent occasion Mr. Christian Allhusen, one of the founders and directors of the great chemical works at Newcastle-on-Tyne, addressing the shareholders of his company, intimated to them that "civilised man requires chlorine, just as material man requires bread, and the fact that we can produce chlorine just as cheaply as any firm or company in the world is the sole excuse for the determined struggle we have carried on, and are now carrying on, for the continuance of our existence." In this sentence Mr. Allhusen referred to the competition which has for a considerable period been carried on in the country between the two great chemical processes of Le Blanc and Solvay. For a number of years past the latter process, which is based upon a well-known chemical reaction that permits of the production of soda by means of carbonic acid acting upon ammonia and brine, appears to have held the field in reference to the production of carbonate of soda, while the process represented by Mr. Allhusen has been first, or at any rate claims to be so, in reference to the economical production of chlorine. It now appears, however, says the *Times*, that both systems are in danger of being superseded by a new process, originated at the establishment of the Aluminium Company, of Oldbury, Birmingham, by Mr. H. Y. Castner, the managing director of the works there. This process differs radically from any of the numerous processes that have been attempted to be put in operation for the electrolytic production of soda. Its essential feature is the employment of a moving body of mercury, which completely separates the products of the electrolysis, and by its movement takes the place of a diaphragm, the amalgam formed by the electric action being decomposed electrically as rapidly as it is so formed. The use of mercury as a cathode is a very old idea, but one which has not hitherto met with any success, the great difficulty standing in the way being the enormous quantity of mercury required in carrying on such a process, and the great quantities to be handled in order to obtain relatively small quantities of caustic soda. Mr. Castner has effectually solved this difficulty at the Oldbury Works, the cells employed, each divided into three compartments, being capable of being continuously rocked or tilted, so as to give to the contained mercury a flowing motion from side to side. Two outside compartments contain the alkaline chloride solution and the carbon anodes, while the middle compartment contains an iron cathode and the caustic solution. The solution of salt or chloride is continuously circulating through the outside compartments, wherein it is being electrolysed, and then returns to saturators, where it is recharged with salt. The electric current, traversing the salt solution, liberates chlorine, and also forms sodium amalgam. The process is, of course, continuous, and it has demonstrated, among other results, that the electrical efficiency is as much as 88·90 per cent.; that no hypochlorites are produced, their production being a defect in other kindred processes; that the solution forming and carrying the electrolyte is in continuous use; that the E.M.F. required for each cell is low, due to the non-accumulation of sodium in the mercury, and particularly to the fact that the electrodes are brought almost into contact.

Anyone who is at all familiar with the phenomena of electrolysis will understand from this rather too technical description that results have been achieved of great importance. The process has now been in regular operation at Oldbury for over six weeks, and it has been found that each cell, which is 6ft. long, 3ft. wide, and 6in. deep, decomposes 56½lb. of salt daily, producing 38½lb. of caustic and 34½lb. of chlorine in 24 hours, for an expenditure of 3½ i.h.p. The caustic solutions produced contain 20 per cent. of caustic soda, and yield by direct evaporation a solid caustic of 99½ per cent. purity, while the chlorine gas is of 95 to 97 per cent. purity, the balance being hydrogen. The cells in which the process is carried on are practically automatic, and require little or no attention. A cell in full operation may be stopped, emptied, taken completely apart, put together again, and started in less than two hours by the labour of two men. The Aluminium Company have erected at Oldbury a plant of 30 cells, with a daily output of 1,200lb. of pure caustic soda and 1,000lb. of chlorine, with an expenditure of 110 i.h.p.

A number of chemical experts who have examined the process, including Sir Henry Roscoe, M.P., Mr. Ludwig Mond (of Brunner, Mond, and Co.), and the chief officials of the United Alkali Company, have expressed a favourable opinion of the process and its prospects.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Portsmouth.—Tenders for the second-hand plant offered for sale by the Corporation have to be in by to-morrow.

Hoylake.—The Hoylake and West Kirby Local Board are prepared to receive proposals for lighting the street lamps of their district by electricity. For particulars apply to the surveyor, Local Board Offices, Hoylake, Cheshire.

London.—Among tenders invited by the Great Western Railway Company, Paddington Station, by the 8th prox. are the following: telegraph instruments, telegraph apparatus, copper wire, G.P. wire, telegraph ironwork and tools, telegraph drysalteries, and carbons for electric light.

St. Pancras.—The Vestry are prepared to receive tenders for the following works in connection with their new central station at King's-road, Camden Town, and several sub-stations: main switchboard, electrical instruments, etc., motor transformers and accessories, wiring and lighting certain buildings. The drawings can be inspected, and specifications, schedules of quantities, and general conditions can be obtained at the offices of Prof. Henry Robinson, 13, Victoria-street, Westminster, on payment of 5s. Tenders are to be sent in by Thursday, October 11.

South Shields.—The following tenders are invited for the supply and erection of the following plant, for the Corporation: Section A—boiler-house plant, including boilers (marine type), fittings, pipes, chimneys, etc. Section B—pump-house plant, including double-acting, slow-speed, circulating and feed pumps, cast-iron tank, pipes, and fittings in connection therewith. Section C—engine-house and sub-station plant, including 100 and 25 kilowatt steam alternators, with double or triple compound engines, steam exciter, circulating pipes, switchboard and instruments, sub-stations, and transformers. Section D—underground work, including rubber-covered cables, cast-iron pipes, boxes, switches, and trenching. Section E—arc lamps, lamp-posts, switches, and transformers. Section F—meters. Firms tendering are at liberty to tender for any section or sections, or for the whole of the sections, but not for part of a section. Copies of specification, including plans, conditions of tender, and contract, can be obtained at the Borough Electrical Engineer's Office, South Shields, on and after 17th inst., on payment of £3. 3s., which sum will be returned on receipt of a *bonâ fide* tender. Tenders, sealed and marked "Tender for Electric Lighting," to be delivered to Mr. J. Moore Hayton, town clerk, Court Buildings, South Shields, by October 31.

RESULTS OF TENDERS.

Dundee.—A tender by Messrs. Siemens Bros., for the supply of a Willans engine and Siemens dynamo, has been accepted by the Electricity Supply Works at £1,466.

Liverpool.—The tender of Messrs. Crompton and Co., Limited, has been accepted for the electric lighting of the coaling jetty, East Float, Birkenhead, belonging to the Mersey Docks and Harbour Board.

BUSINESS NOTES.

Hull.—Waltham-street Chapel has been lighted electrically.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2,721.

Folkestone.—The Town Council have deferred the consideration of Councillor Baker's electric light scheme.

Blockley.—A public meeting is to be held to consider the question of the future lighting of the streets.

Knightsbridge, W.—Messrs. Roger Dawson, Limited, are putting in about 3,000 lights in Wellington Court, Knightsbridge.

Globe Telegraph and Trust.—The directors announce the payment, on the 18th prox., of an interim dividend of 1s. 3d. per share.

London, E.C.—The Wool Exchange is having an electric light installation, which is being carried out by Messrs Roger Dawson, Limited.

Appointment.—As will be seen from our advertisement columns, the Bradford Corporation want a man to erect Crompton-Howell accumulators.

Nottingham.—St. Paul's Church has been restored and decorated. The electric light installation has been carried out by Mr. Joseph Blackburn.

Eastern Extension Telegraph Company.—The Board has declared an interim dividend of 2s. 6d. per share for the quarter ended June 30 last.

Halifax.—Up to the present time about 100 persons have signified their intention of becoming customers of the Corporation for the electric light.

Eton.—The Local Board have received a letter from the Board of Trade announcing the revocation of the Windsor Electric Light Supply Order of 1890.

Swansea.—The Electric Light Committee of the Swansea County Council are taking preliminary steps towards getting the town lighted by electricity.

Broughty Ferry.—The Northern Electric Supply Company, of Aberdeen, have given notice that they attend to apply for a provisional order for the burgh.

Coventry.—The City Council have affixed their seal to mortgages on rates—£2,000 for electric lighting and £100 to repay existing loan of that amount.

London, W.—Thomas's Hotel, Berkeley-square, is being lighted electrically, the work being carried out by Messrs. Roger Dawson, Limited, of Berners-street, W.

Clark's Engineering and Machine Tool Company, Limited.—This Company has been registered, with a capital of £5,000, to carry on business as ironfounders, mechanical engineers, etc.

Woolwich.—The Woolwich Electric Lighting Company have given notice to the Local Board that they are going to extend their mains from High-street to light the parish church.

Dewsbury.—There have been 60 applications for the post of electrical engineer to the Corporation, and Mr. J. B. Mitchell, of Bradford, has been appointed at a salary of £180 a year.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending 16th inst. amounted to £1,084, as compared with £708 in the corresponding week of last year.

Penzance.—Mr. W. T. L. Perry has had installed the electric light at his premises in Parade-street, the motive power being supplied by an engine used in his fish-curing business. The installation was carried out by Mr. V. Corin.

Blackburn.—The art gallery has been lighted electrically, under the supervision of Mr. Walter Leake. A 40-h.p. "National" gas-engine has been installed in the basement, driving a Yorkshire dynamo of an output of 120 amperes and 110 volts.

Hove.—The work in connection with the installation of the electric light in the Town Hall is now nearly completed. The whole building has been wired, and the light is ready for use everywhere except in the large room, the Board-room, and the committee-room.

Friesland Manufacturing Company, Limited.—This Company has been registered, with a capital of £18,000 in £1 shares, to enter into an agreement with W. M. Callender, and to carry on business as manufacturers of and dealers in plastic material, and as engineers and electricians.

City and South London Railway.—The receipts of the Company for the week ended September 16 were £826, against £758 for the corresponding week of 1893, or an increase of £68. The total receipts for the current period of the present half-year amount to £9,402, as against £8,906 in the corresponding period of 1893.

Liquor Register Syndicate, Limited.—This Company has been registered, with a capital of £18,000 in £1 shares, to acquire and develop certain patents, and to carry on the business of electricians, mechanical engineers, suppliers of electricity, and manufacturers of appliances for registering receipts of money and sales of goods.

Electric Plant for a Colliery.—A new colliery is being opened out on the Park Hall estate, near Eckington, by Mr. Job. It is intended to work the mine entirely by electric power, and to have it lighted both on the surface and underground electrically. The electrical work will be carried out by Messrs. John Davis and Son, of Derby.

Coventry Electrical Engineering Company, Limited.—This Company has been registered, with a capital of £5,000 in £1 shares, to acquire and carry on the business of electrical engineers and machinists now carried on by the Coventry Electrical Engineering Company at Ryley-street, Coventry, and to enter into an agreement for that purpose.

Bromsgrove.—The Town Local Board have been considering the question of electric lighting. Mr. Hall, pursuant to notice, moved that the Board consent to the application of Messrs. Hemming and Co. to lay down apparatus for electrical lighting in the district, all legal rights of the Board being reserved. This was seconded by Mr. Leadbetter, and after some discussion was passed.

Aberdeen.—At a joint meeting of the Watching and Lighting and Gas and Electric Committees of the Town Council, it was reported that the cost of the electric lighting of Union-street, at 7d. per unit, was £262 2s. 10d. per annum. It was decided that the gas department should supply the current for street-lighting at 2½d. per lamp per hour, the Lighting Committee to bear the cost of the carbon and maintenance.

Brush Company.—The directors of the Brush Electrical Engineering Company, Limited, recommend a dividend at the rate of 6 per cent. per annum on the preference shares, and at the rate of 5 per cent. per annum on the ordinary shares of the Company for the half-year ended June 30, 1894, carrying forward a sum of about £3,700 to next account. The transfer books will be closed from September 25 to October 8, both inclusive.

Chester.—Councillor T. Browne, at a meeting of the Town Council, asked when the Council were to be informed upon the actions of the Electric Lighting Committee. Councillor Deeley said he was of opinion that they could start an installation of the electric light in Chester with at least 5,000 incandescent lights, apart from the street-lighting. A meeting of the committee was to be held shortly, and the subject further considered.

Huddersfield.—The Electric Lighting Committee of the Town Council have recommended that discounts of 2½ per cent. be allowed to consumers of over 1,000 units up to 10 per cent. on a consumption of over 4,000 units in the half-year; that the supply of electrical energy for motive and domestic purposes other than lighting be charged at the rate of 4d. per unit; and a revised scale of meter rents adopted. These recommendations have been approved.

Liverpool.—The Works Committee of the Mersey Docks and Harbour Board have recommended the Board to provide electric

Digitized by Google

lighting installations at (1) the new coaling jetty, Duke-street Bridge, East Float, Birkenhead, and (2) at the Albert Dock warehouses. Mr. Glynn said he was sure the Board would be glad to hear that the old Albert Dock was going to be revived and the electric light placed there. The recommendation was approved.

Warminster.—The committee of the Local Board appointed to consider the desirability of extending the electric light through the town have recommended that the light should be carried to the Obelisk, by the erection of six additional arc lamps, at a cost of £184. 10s., and £50 for a dynamo. Mr. Smith proposed the adoption of the committee's report, and that the committee be empowered to carry out the work, and this was eventually agreed to.

Halifax and Bermudas Cable.—The directors, in their report for the year ended June 30, state that the result of the working is a profit of £328, as compared with £1,717 for 1892-93. The cable receipts in the past year were £3,462, as compared with £4,856 in the preceding year. This decrease is due to the partial failure of the crops of the island, the absence of distressed shipping, and a decline in visitors' messages incidental to the prevailing business depression.

Dover.—In reference to the notice of intention to lay electric light mains in Wood-street, which was not included in the original scheme, the surveyor recommended that permission should be granted. The surveyor presented the account of the work of opening out the pavements for laying the mains for August, which amounted to £186. 6s. 1d. The total cost has been £681. 13s. 10d., of which about £280 has been paid. The account was ordered to be forwarded to the company.

Altrincham.—The clerk to the Local Board has received a letter from the Board of Trade in reference to the application of the Electric Lighting Act to the district by the Altrincham Electric Supply Company, enquiring as to the measures taken for securing the safety of the public and a sufficient supply of the electric light, together with a description of the system by which the energy was to be supplied, and asking for the observations of the Board on the matter. This was referred to the Fire and Lighting Committee.

Wigan.—At a meeting of the Gas Committee held on Monday, when there were present Mr. Holmes (chairman), the Mayor, Messrs. Benson, Ashton, Richards, Hilton, John Johnson, Millington, Phillips, Rigby, and Fyans, the report of the Electrical Lighting Sub-Committee was received. The committee expressed their pleasure on receiving the report, and resolved that the sub-committee be requested to invite five or six manufacturers of electrical plant to submit schemes and tenders as suggested in the report of the sub committee, and that copies of the report be circulated to the members of the Council.

Llandudno.—Consequent upon the receipt by the Improvement Commissioners of a notice from the Llandudno Electric Supply Company of their intention to apply to the Board of Trade for a provisional order to supply the town with electricity, the Water and Gas Committee recommended the Commissioners to apply themselves for a provisional order authorising them to supply electricity for public and private purposes. As an amendment to this, Mr. Jones moved that prior to the application being made a public meeting be held in order that the question might be fully ventilated. Upon being put to the meeting the amendment was lost.

Bootle.—Councillor I. A. Mack has moved at a meeting of the Town Council "that application be made to the Board of Trade for a provisional order, to be confirmed in the next ensuing session of Parliament, authorising the Council to supply electricity for public and private purposes within the borough, and that the Parliamentary and By-Laws Committee be instructed to take the necessary steps for this purpose." He explained that it was only a provisional application which would confer on them the right of lighting the borough with electricity. If they did not secure this power a private company might step in, and they would then be in the same position as they were now with the gas company. The recommendation was carried.

New Swindon.—Mr. Hinton, at a meeting of the Local Board, mentioned that Mr. E. C. Skurray, of the firm of Messrs. Skurray and Son, of the Town Flour Mills, has offered to light a lamp on the Whale Bridge, in Princes-street, if the Board would bear the expenses of laying the wires, etc., from the mill. Mr. Skurray had told him that since the works at the mill had started the electric light had proved most successful and inexpensive. He (Mr. Hinton) thought the Board would do well to accept Mr. Skurray's offer, and try the experiment. With that object in view, he proposed that the ward committees of that district be asked to consider the matter. Mr. Batt: Could we not light Princes-street? Mr. Thomas: I should like to see it carried into the main street. After some further remarks, Mr. Hinton's proposition was agreed to.

Bath.—A meeting of the City of Bath Electric Lighting and Engineering Company, Limited, has been held, the chairman, Mr. T. O. Callender, presiding, to authorise an application for a provisional order. The company at present holds a seven years' license only, and its operations are confined to a certain area of the city. It is proposed by means of a provisional order to extend the right of supply to the whole of the city, and also extend the time limit of the authority. The consent of the local authority has not yet been formally applied for, but on receipt of the statutory notice of the intention of the company to seek for the powers, it has decided to withhold its assent. The Chairman, who moved the formal resolution authorising the application, said that when the intentions of the company were clearly laid out before the authority he did not think they could persist in objecting. The resolution was carried.

Yarmouth.—The report of the Electric Lighting Committee of the Town Council contained a statement by the borough surveyor that the cost of lighting the 24 lamps on the Marine-parade and Regent-road had been for the month of August £9. 16s. for labour, £9. 14s. for gas, and £3. 10s. for waste oil and sundries—making a total cost of £24. The committee recommended discontinuance of running the temporary installation after September 30 until such time as the permanent plant should be ready. Messrs. Laurence, Scott, and Co., of Norwich, have taken new premises at 28, Regent-street, Yarmouth. The shop taken by this well-known firm for business purposes has been fitted up with a dynamo of their own make (I.X.L.), and a gas-engine supplies the motive power. Various forms of electroliers are shown, beside all the necessary fittings for private houses and business firms.

Felixstowe.—Resolutions have been proposed at a meeting of the Felixstowe Local Board, the first offering the principle that the water and gas should be brought into the hands of the Local Authority, and the second referring to the whole Board in committee to interview the directors of the companies concerned with a view to purchase. These resolutions were carried unanimously, the only alteration in the wording of the resolutions as submitted being the addition of the words "if reasonably practicable," on the suggestion of Mr. Downing, who also explained that in framing the resolution as to the Authority having control of the lighting, the words "gas, electricity, or other light" were embodied, because if the negotiations with the gas company did not prove satisfactory, the surplus power of the two engines to be used in the sewage works could be utilised in the lighting of the town with electricity.

Eveley. — Messrs. Drake and Gorham are putting up an installation for Mr. J. T. Smithies, of Eveley, Hampshire, where the power will be supplied by a turbine, the number of lights being about 100. The D.P. accumulators will be capable of supplying 91 16-c.p. 60-watt lamps for four hours, or 58 for nine hours. The dynamo will be a five-unit machine of the Electric Construction Company's make. The mains between engine-room and house will consist of hard-drawn copper wire fitted on porcelain insulators, and the installation will contain a patent Nevile accumulator switch to prevent the dynamo from discharging itself through the battery should the power fail from any cause. A telephone line will be fixed between the engine-room and house to avoid the necessity of a messenger being sent with instructions to the attendant. The firm have also just completed an installation at Mr. Heath Harrison's house, Lecourt, in the same county.

Direct Spanish Telegraph Company.—The report for the half-year ended June 30 states that the accounts for the half-year show, after providing for debenture interest, a balance to the credit of profit and loss of £4,075. The traffic receipts show a decrease of £868 as compared with the corresponding period of 1893, this decrease being due to the continued stagnation of business in England, Spain, and France. The working expenses are £43 less than those for the corresponding period of last year. After adding the usual sum of £2,500 to the reserve fund, the balance of profit and loss amounts to £1,575. To this the directors propose to add £951 from interest and profit on investments, and recommend the payment of the dividend at the rate of 10 per cent. per annum on the preference shares, and a dividend, free of income tax, of 1s. 8d. per share, being at the rate of 4 per cent. per annum on the capital paid up from the due date of payment on the ordinary shares of £5 each. The reserve fund will then amount to £21,270.

Edinburgh. — The sub-committee of the Edinburgh Town Council on electric lighting recommended to the Lord Provost's Committee that a deputation of three members should go to London to select a lamp for public lighting in Edinburgh, several specimens having been fitted up at Westminster by the Corporation's consulting engineer. On Tuesday, at a meeting of the Town Council, the Lord Provost, in connection with the recommendation to appoint a deputation to inspect the specimens of electric lamps for public lighting which the Corporation's consulting engineer had fitted at Westminster, explained that Prof. Kennedy wished to throw the responsibility of the selection on the Corporation. Some demur was made to another deputation, and Mr. Waterston proposed that only one member of Council should go. Finally it was agreed that Bailie Dunlop and Councillor Mackenzie should form the deputation. The Electric Committee earlier in the day accepted an estimate for 175 lamp-posts for electric arc lamps to light the streets sanctioned. The contractors for the posts are Messrs. Mackenzie Bros., iron-founders, Edinburgh.

Ravensthorpe.—The installation of the electric light by the Ravensthorpe Self-Help Co-operative Society has been celebrated by a festival which was promoted in connection with the local society's women's guild. The plant has been put in by Messrs. Ullathorne and Hartley, electrical engineers, of Bradford and Halifax, the fittings and appliances being of the latest and most approved style. There are 11 arc lamps of 2,000 c.p. each, and eight of half that illuminating capacity. In addition to these, 102 incandescent lights are placed about the interior of the premises, their power varying from 8 to 16 candles. The preliminary cost, including new engine-house, engine, and dynamo, has been £747, but it is computed that the saving in depreciation of stock alone will go a long way towards contributing to this outlay. The hall was brilliantly lighted on Saturday by four of the large lamps, and the effect was very pretty. Mr. Eli G. Rothwell, president of the society, occupied the chair at the evening meeting. Mr. Ullathorne, in the course of a few remarks, spoke of the superiority of electricity over gas for illuminating purposes, and claimed that in actual cost—apart from its advantages in the shape of saving in depreciation of stock and property, as well as the physical

Digitized by Google

comforts derived from its being a non-heat-producing light—it was incomparably cheaper than gas.

Wakefield.—The City Council have held a meeting at which it was stated that the town clerk had reported to the committee that the Corporation's electric lighting order had been confirmed by Parliament; and he was instructed to arrange for a further meeting of the committee, and the attendance of Mr. Hammond, as soon as the site for the proposed new sewage works had been finally decided upon. As he was about to put these minutes to the meeting the Mayor remarked: I should like to see the light, gentlemen. Councillor Reynolds rose to ask what was being done in the matter of electric lighting. Councillor Nicholson (chairman of the committee) was understood to say, in reply, that his committee were waiting for the Sewage Committee to know whether they could have a certain site for their electric works. Councillor Reynolds wanted to know if it were an understood thing that the electric lighting was going to be a part of or connected in any way with the sewage department. If so, it seemed a very comical mixture. Councillor Nicholson rejoined that the committee were simply waiting for the land required. The minutes were then confirmed.

Fermoy.—On Friday evening an intimation was sent to the Fermoy Town Commissioners that Mr. C. J. Furlong would meet them at the Court House *re* the project of introducing the electric light as an illuminant into Fermoy. At the meeting Mr. Wm. Eager, C.T.C., presided. Mr. Furlong, in the course of his remarks, expressed the hope that the Commissioners would be successful in their project. As to the use of his mill wheel as motive power, the only difficulty to contend with would be that at times the river would be in flood, when the back water would prevent the wheel from working. At all other times the wheel would be sufficient to generate any amount of electricity required. As to cost he had not gone fully into that, but he thought that a charge of £2 per year per horse-power would be reasonable and equitable. For the public lighting of the streets he considered 32 h.p. would be sufficient, which would be equivalent to an annual rental for the wheel and water supply of £64. If a private supply were needed for houses and shops, he thought that 80 h.p. would be the maximum required, that was in the event of the supply being taken in generally by private consumers. If the project were successful, he would be the first to take a private supply. After some further discussion, the town clerk (Mr. P. J. Lane) was directed to make enquiries as to the cost, working, etc., in towns such as Carlow, Killarney, Kingstown, etc., where the electric light has been adopted.

Winchester.—A few weeks ago the Corporation, by a majority of two, decided to apply to the Board of Trade for a provisional order to enable them to borrow a large sum to light the city with electricity, and thus secure themselves against the possibility of a private company getting an order. There has since been held a special Council meeting to confirm the resolution to apply for the order and empower the town clerk to spend £250 in obtaining it. There had already been spent in preliminaries the sum of £100. A memorial from over 600 ratepayers, protesting against the scheme and the obtainment of the order, was presented and read. Mr. Shenton moved, and Mr. Gibb seconded, that the resolution should be confirmed, and they repeated the arguments used a few weeks ago. A discussion followed that lasted nearly two hours. In the course of it the local gas company was stigmatised as a monopoly, and the recent reduction of its prices was asserted to be due to fear of the electric lighting scheme. Several speakers said that they only supported the proposal to obtain the provisional order as a protection for the ratepayers and to secure to them any profit there might be in electric lighting. Others contended that if any expense would fall on the rates they would not go beyond the provisional order. There was a large muster of ratepayers in the Council-chamber, who applauded the opposition once or twice; and the Mayor (Alderman Stopher) threatened to have them turned out. On a division being taken, 11 voted for the confirmation of the provisional order and 10 against. It is understood that every step in the scheme will be opposed, and that the elections in November are likely to be largely influenced by the question.

Middlesbrough.—A committee of the Middlesbrough Town Council, consisting of Alderman J. A. Jones, chairman, the Mayor (Councillor Baker), Alderman A. Hinton, together with Mr. D. Terrace, gas manager, and Mr. Alf. Sockett, deputy town clerk, having visited the electric lighting works at Newcastle, Leeds, Bradford, Halifax, Huddersfield, and Blackpool, have furnished the following report to the Corporation: "(1) That the electric light is a paying business, and a profit is to be made by its adoption. (2) That the consumers in all places testified to the fact of its being superior to gas, and would on no account return to the latter. (3) That its sanitary effects are in the right direction and admitted by all consumers. (4) That the consumers' goods are not injured as in the use of gas. (5) That the several systems acted well, though the committee were exceptionally pleased with the installations at Blackpool, Huddersfield, and Leeds; and (6) that having regard to the fact that a large sum of money will be immediately spent in the extension of our gas plant, and, in the event of the electric light not being adopted, that an additional sum will ere long be required for the purchase of further premises in Durham, East, and Bath streets, and probably elsewhere, and having further regard to the fact that the electric light is rapidly extending over the land, and that our neighbours are moving forward on these lines, and that it is not desirable that a private company should obtain powers for Middlesbrough to be approached hereafter for purchase (as in the case of Newcastle), the sub-committee are of opinion that it would be in the true interests of the borough to proceed forthwith with the laying down of an electric installation at a cost not exceeding £25,000."

Ayr.—A minute of the Lighting Committee of the Town Council bore that the clerk read the following letter received from Mr. Hammond: "Great Trinity-lane, E.C., London, August 31, 1894. The time has arrived when the Board of Trade should be asked to approve the system that has been fixed upon at Ayr, and I shall be happy to take up the matter with the Department immediately. In order to enable me to do this, will you kindly write a letter to the assistant secretary, Board of Trade, advising them that I hold the position of consulting engineer to the Corporation, and have received your instructions to apply for approval of system." The meeting instructed the clerk to write to the Board of Trade in the terms suggested. The clerk also read the following letter from the Under Secretary for Scotland—namely: "Whitehall, September 1, 1894. Electric Lighting. Sir,—With reference to previous correspondence I am now directed by Sir George Trevelyan to intimate to you that he approves, in accordance with the Electric Lighting Acts, of the raising of a loan of £15,000 by the Provost, Magistrates, and Council of the burgh of Ayr, as Police Commissioners of the burgh, for the execution of works under the Ayr Burgh Electric Lighting Order, 1890. I am to add that provision for the liquidation of the loan within a period not exceeding 30 years will require to be made in accordance with Section 86 of the Public Health (Scotland) Act, 1867, which regulates the repayment in the present case, and for the information of the burgh authorities, in the event of the method of repayment by means of a sinking fund being adopted, I am to enclose a copy of sinking fund regulations framed by the Secretary for Scotland under Section 67 (3) of the Local Government (Scotland) Act for the guidance of the county councils constituted by that Act.—I am, etc., WM. C. DUNBAR."

Mansion-Lighting.—The installation of the electric light at Clewer Park, the residence of Sir Henry D. Gooch, has just been completed, and adds another to the list of electric-lit residences within the neighbourhood of Windsor. A direct vertical steam-driven dynamo is used, capable of developing 65 volts and 60 amperes. In the house next to the boiler and pumping room are the cells, 27 in number, which, when fully charged, will supply a 100 8-c.p. lights for 10 hours. The mains for conveying the current are carried underground by pipes from the battery-room to the house to a distributing board in the main corridor, the distribution being divided into 12 circuits, and from which all the rooms are lit. The outdoor offices, stables, coach-houses, and yard are all fitted with electric lamps. The dining-room is lit with a centre lamp, with rich crimson shade, which is fitted with a double switch for lowering or raising the light at pleasure, while on the side-table are two movable lamps which were formerly used as oil lamps, and have now been converted to their new use, the lamp screws having been utilised as switches. The conservatory adjoining the dining-room is lit by three lights. The drawing-room is artistically fitted up with electroliers, which are fitted with 24 electric candle lamps of Venetian glass, and movable lamps are on the tables, from which the wires can be detached by removing the plug, and removed to any part of the room. On the ground floor, the servants' rooms, including the butler's pantry, dining-room, etc., and a photographic dark room, are all fitted with electric light. On the upper floors, all the bedrooms have been fitted up on the latest approved methods. The billiard-room has five electric lamps, and also six lights over the table. The electric wires are carried underneath the floors and concealed in the walls, and everything has been carried out on a most complete scale. There is also telephonic communication between the house and the stables. The whole of the work has been carried out by Messrs. Roger Dawson and Co., of Windsor and London.

Radcliffe.—The Local Board have held a meeting at which it was reported that at a meeting of the Electric Lighting Committee, held on September 5, it was resolved that Mr. Bennett's offer to prepare plans and do everything requisite for obtaining the provisional order be accepted; that, if it be decided to proceed with the electric lighting of the district after the provisional order has been obtained, this Board do recommend that Mr. Bennett be appointed to carry out the works at the terms stated by him in his letter of July 13 1894; and that Mr. Bennett do prepare the plans for an installation in the first instance of not more than 6,000 8-c.p. lamps, and that the works be laid out in such a manner as to enable this Board to make future extensions therein. The Chairman said that the committee had no extravagant notion of going on too large a scale, and, as the Board would see, they had limited the maximum number of lights to 6,000 8 c.p. lamps. They estimated, so far as their information went, that an expenditure of something like £10,000 would put them down a plant, station, and all that was necessary for 5,000 or 6,000 8-c.p. lamps to distribute over, at all events, the most populous part of the district, so that the committee were desirous of keeping this matter within reasonable limits; and so far as he could form an opinion—and he thought the committee could form an opinion from the particulars supplied to them—the expenditure of that £10,000, when it took place, would not only not prove an addition to the rates, but would be a something which would to some extent, especially if it were appreciated by the public of Radcliffe as it was in other districts, do something in relief of the rates of the district. In reply to Mr. Lowe, the Chairman said that an 8-c.p. lamp would give considerably more light than their ordinary street lamps. Mr. Thornley asked whether in expending the £10,000 there would be provision made for extension. The Chairman replied in the affirmative, and said that in their scheme they had given particular instructions that everything should be so arranged that they could

Digitized by Google

double the number of lights at much less cost. The minutes were approved.

Cardiff.—A meeting of the Cardiff Lighting Committee was held on Tuesday morning, under the presidency of Councillor Vaughan. It was reported to the committee that a large number of lamps were purposely broken. During the last two months 150 were broken by stone throwing alone. Alderman Carey stated that at the last meeting of the Watch Committee the members congratulated themselves upon the small number of breakages reported by the police. The borough engineer, Mr. Harpur, stated that the police reports on this matter were valueless. Not 5 per cent. of the broken lamps were reported. The committee considered a draft report which had been prepared for allowing the National Telephone Company to place their wires underground. As it was thought that eventually the tramways would be worked by electricity, the committee refused to recommend the adoption of the agreement which had been forwarded to them for their consideration by the Public Works Committee. The question of renting motors was introduced by Alderman P. W. Carey, who said there were many tradesmen, such as hairdressers, sausage-makers, people with lifts, and so on, who would use electricity, when the town's project was ready, if they could rent motors from the Corporation. A 3-h.p. motor would cost over £20, which was a large sum to disburse for some tradespeople. It was to the interest of the Corporation to have as much electricity used during the day as possible, and they could afford to be more generous to day consumers than to night consumers. The Borough Engineer thought the suggestion was practicable, but the subject was deferred for further consideration. The Borough Engineer reported that the Great Western Railway Company had refused to put in a siding at the electric works. Mr. Massey said he thought the site was selected because of its proximity to the railway. The Borough Engineer said that was so, but the company refused to make a siding because they said they would not be able to work their traffic if they did so. There was a siding 200 yards nearer the town, and the coal would have to be carted from there. It was decided to appoint a deputation to wait on the general manager of the company when some of the members next go to London.

Mr. Arthur Shippey.—A receiving order having been made on the 2nd ult. against Arthur Shippey, described as an electrical engineer, of 18, King-street, Cheapside, E.C., accounts have been furnished disclosing liabilities £4,101, of which £1,170 are unsecured, with an estimated surplus in assets of £4,797. From the observations of the official receiver (Mr. A. H. Wildy) and the statements of the debtor, it appears that he was adjudged bankrupt on July 29 1892. He then filed a statement of affairs showing liabilities £1.852, and an estimated surplus in assets of £5.916. No dividend has yet been paid, and the debtor has not yet obtained his discharge under those proceedings. After this adjudication he commenced to carry on business as an electrical engineer with a capital of £50 advanced to him by a relative. In 1886 another firm of electrical engineers commenced an action against him for infringement of patent rights, and he consented to an injunction being granted against him on certain terms In December of the following year he sold his business to a limited company entitled Shippey Bros., Limited, for £8,000, of which £3,000 was to be paid to him in cash by half-yearly instalments of £500, and the balance in shares. He asserts that he received no cash, but accepted further shares in lieu thereof; that £1 500 in cash or shares may be still due to him, and that he now holds no shares whatever, having transferred them all to various creditors as security for their claims. He adds that he expects that Shippey Bros., Limited, will shortly be bought out by a new company, and he anticipates the shares will then be of some value; further, that the company is under agreement to pay him a salary of £120 a year, but that owing to the injunction granted against his patents, business had not recommenced, and the salary has not been paid. The debtor attributes his present position to the injunction referred to, and to a loss upon a contract in 1887 for lighting Herne Bay with electric light, which was stopped by the injunction. The official receiver remarks that nearly the whole of the debtor's liabilities appear to have been contracted over three years ago. The valuation of the securities held by the creditors fully and partly secured (£8,099) is that of the debtor, who admits that their realisation is subject to contingencies, and to the obtaining of a market for them. The official receiver states that the debtor has been required to file a statement of his reasons for anticipating a surplus on realisation of his assets.

Barnet.—Mr. Robert Smith, of Barnet, writes to a local paper as follows: "A proposal to undertake the electric lighting of Barnet is now before the Barnet Local Board. An offer is made by Crompton and Co., Limited, in the following terms: (*a*) that the company puts down plant for the supply of public and private lighting for £10 000, this sum to be found by the Board; (*b*) that the Board pays the company £500 a year for the public lighting; (*c*) that the company uses the plant for the supply of private lighting on paying the Board £350 a year for five years, and £500 for two years; (*d*) that the agreement be for seven years, renewable on arbitration terms. I beg to submit the following reasons against this proposal being accepted by the Board: (1) That £10,000 is far too large a sum for Barnet to provide for a speculation, seeing that the whole ratable value of Barnet is only about £20,000; (2) that the electric lighting of the streets would be on a seven years' contract, and would cost about £50 yearly more than the present gas lighting, which is on a yearly contract; (3) the interest and sinking fund on the sum of £10,000 would be about £500 a year, which, with £500 for street-lighting, would involve an annual charge for the scheme of £1,000. *Per contra* the Board would receive £350, rising to £500 per annum, for the private lighting. On balance, the expenditure of the Board would be increased by £200 per annum, which would have to be met by an increase of 2d. in the Local Board rate. I gather from the proceedings of the Board, reported in the *Barnet Press*, August 25, that Mr. Morse, the chairman of the Electric Lighting Committee of the Board, would be in favour of the agreement if its terms were improved and its duration extended to 21 years. This suggests the question what would happen if Crompton and Co., Limited, were unable, through trade depression or financial crisis, to carry out its part of the contract. It is possible that the Board might have to work the concern at great loss. Crompton and Co., Limited, was formed in 1888 to take over an existing business. For the first four years the dividend on the ordinary capital ranged from 5 to 8 per cent. per annum, and then fell to 2½, and for the year ending March 31 last no dividend was paid on the ordinary capital, and the preference dividend was only half paid. In the report the directors propose to write off £20,000, a sum nearly equal to half the ordinary capital of the company. The £5 preference shares are quoted about £2 in the London Stock Exchange official list. In the balance-sheet attached to the report, among the assets appears the item 'Goodwill, £30,000.' The electric lighting of Barnet should be left over for the new Council which will shortly replace the present Board. It is certain that the Local Government Board will approve of no scheme without reference to that Council."

Kingston.—Councillor Collings moved, and Councillor Walker seconded, at a meeting of the Town Council, the confirmation of the Lighting and Market Committee's minutes. Councillor Baker moved, as an amendment, that the paragraph, "That all disused gas lamps be removed, and that the town clerk communicate with the gasworks manager on the subject, and request that the columns be placed in the Corporation yard at Ham-road," be expunged. He said it was unwise at the present moment to take away the gas lamps, because the previous night all the electric arc lamps in the town went out. The town was in darkness. The lamps had not been satisfactory since they were erected, and it would be as well to allow the gas standards to remain where they were until the light was perfect. They would not get damaged in the present position, but if they were taken down to Ham-road they probably would. He also remarked that he thought the arc lamps went out on the Sunday evening. Alderman J. Marsh asked if the chairman could give any reason for the removal of the gas columns. Councillor Moatt supported the action of the committee. Councillor Davison pointed out that they were about to lay down paving in London-street, which would necessitate the extension of the kerb into the roadway, and it was desirable that the paving should not be disturbed after it was laid down. Councillor Nuthall asked if it was true the lights went out on Monday night? He was in town, and he did not notice it. Councillor Carn stated that the approach to the bridge was as dark as pitch Councillor Collings, replying upon the discussion, said the fact was that the lights were put out purposely. The committee knew, and perhaps some members of the Council were aware, that at the present moment the works were not complete. They had never had them completed as yet, and they were still in the hands of the contractors. On Saturday some portion of the piping that connected the condensing apparatus with the well was sent back to Birmingham, and the result was that the condensing apparatus had not worked, and does not work. Consequently more work was thrown on the boilers. The boilers themselves had been a source of trouble to them, and they had been obliged to turn from one boiler to another in order to keep the light going. On Monday No. 2 boiler developed signs of weakness, and they considered it necessary to maintain the efficiency—and they must admit it had been efficient from the start—of the house and shop lighting and discontinue for a short time the lighting of the streets. It was better to do that than to impair the house and shop lighting, which had been perfect from the commencement. Councillor Baker: That being so, I will withdraw my amendment. The Council consented, and the motion was then carried.

Worcester.—At a meeting of the Watch Committee a letter was read from Mr. C. W. Dyson Perrins, asking the committee whether they could entertain the idea of supplying his house at the top of Malvern Link with electric light. Mr. Perrins explained that he should want sufficient current for from 200 to 300 lamps, as well as for one or two motors. He added his belief that the Malvern Local Board had allowed the provisional order which they obtained some years back to lapse, so that he presumed there would be no difficulty on that score. The matter was referred to the sub-committee. A letter was read from the sheriff—who had anticipated inability to attend the meeting—stating that, as requested by the Mayor, he had had an interview with the gas company with reference to the difficulty that the electric lamp-posts were erected exactly on a line with the gas-main in High street Mr. Millington reported that he had arranged the following terms: (1) that the gas company should at once proceed to alter the mains so as to allow of the erection of the standards; (2) that the Corporation should pay all expenses connected therewith, and that the Corporation should also pay reasonable charges by Messrs. Stallard and Son in connection with the matter. The Sheriff explained that unless they had arranged matters, a delay of six weeks would have been caused. Alderman Caldicott: I don't see why there should be any legal expenses for stopping a hole up and laying a pipe. The action of the Sheriff was confirmed. A letter was read from Alderman Ernest Day, apologising for absence, and calling attention to the "enormous obstruction"

Digitized by Google

of electric light standards being fixed in the city. He suggested that the Watch Sub-Committee should go carefully through the plan, and where necessary arrange for hanging lamps or lights from brackets He was satisfied that the former in the main streets and narrow thoroughfares would be infinitely superior to the obstructive posts. The posts ordered could no doubt be utilised in other positions. Unless the matter was seen to, he was satisfied that serious complaints would be made against the Corporation, and might in a way cause a prejudice against electric light. He added that the positions for transformers appeared to be fixed in the pavement in the most objectionable places, and unless very great care was exercised in protecting openings, when the covers were off accidents would occur. The matter was referred to the sub-committee. Mr. G. E. Abell, assistant general manager of Lloyd's Bank, wrote stating the lamp being erected in front of the bank door could not fail to be a great nuisance to people driving up to the bank, and as it was a semi-public institution, he thought its convenience should be specially studied in a matter of kind. He therefore asked the committee to call the attention of the Streets Committee to the subject, with the view to the lamp being placed a few yards distant, and at a more convenient spot. Alderman Holland urged that the committee should have had a plan before them in order to decide where the standards should be placed. The Mayor, however, pointed out that they were not experts in the matter. The reference of the letter to the sub-committee ended the meeting.

Hertford.—In our last week's issue we referred to the public meeting which was held at Hertford on the subject of the electric lighting scheme. The resolution then passed has been considered by a special meeting of the Town Council. Considerable interest was taken in the meeting, a good number of ratepayers being present. The Mayor read some correspondence he had had with the Board of Trade with reference to the provisional order, the effect of which was that he had that morning received a letter from the Board of Trade stating that they would refrain from revoking the order on receiving an assurance from the Corporation that they intended to exercise their powers within a reasonable time. But if the Corporation refused to give effect to the order, and an application was received from a company, it would be for the Board of Trade to consider whether they should not revoke the existing order. Alderman Shelley proposed that the electric lighting scheme proposed by the engineer—extended so as to supply the Hertford General Infirmary—be carried out as speedily as possible. He strongly urged the Council to adopt the motion, and said that additional applications for the light had been received since the last Council meeting, bringing up the total applications to 1,400 lights. Councillor Ginn seconded the motion, and hoped the Corporation would give a substantial vote in its favour, as he firmly believed the light would be a success. Councillor Garratt moved an amendment, "That the report of the Lighting Committee as presented to the Town Council be referred back for further consideration, as it is considered that the details as to the profit and loss are incomplete in several important items." The Mayor: I am sorry to do it, but we have had an amendment before in almost the same words, and I rule it out of order. Councillor Garratt warmly protested against the ruling, and remarked that the Mayor was always trying to stop him. The Mayor said Mr. Garratt was at liberty to move that the report be referred back to committee, but he would not allow an amendment to be put in exactly the same terms as before. Councillor Garratt: I can move it again. Councillor Willshaw asked under what standing order the Mayor based his ruling; and this not being given, Mr. Wilshaw remarked: Then we had better throw it up. Councillor Garratt: I move the amendment. The Mayor: You can move an amendment that it be referred back to the committee. Councillor Robinson said he could not conceive any reason why the amendment should not be moved and the reasons given for it. He considered the Mayor was entirely out of order in his ruling. Councillor Garratt: I move the amendment. The Mayor: You can move that it be referred back to committee, and state your reasons for it, but I rule that you cannot move it on grounds that have been moved before. Councillor Garratt then stated his reasons for moving the amendment, pointing out several instances where, in his opinion, the estimates were inadequate. He believed it would result in a positive loss, and until it could be shown that the light could be produced without loss he should oppose it. No doubt the time would come when the light could be produced at a profit, but that time had not yet arrived. Councillor Robinson seconded the motion, contending that the estimates were very inadequate, both in regard to the capital required and the annual cost. The details were also imperfect, and until they could look forward to a scheme that would not burden the town he should oppose it. Alderman Dr. Shelley: As the amendment has been ruled out of order in this form, it is open to any other member to move as an amendment that the matter be referred back to the committee. The Mayor: Oh, yes. Addressing Councillor Garratt, he said: It is purely a matter of principle. Councillor Garratt: So it is with me After a pause, Councillor Garratt, again rising, said: If you intend to persist in this course, it is my intention to withdraw. Soon afterwards, Councillor Garratt got up and left the room, followed by Councillors Robinson, Brickwell, Pollard, and Wilshaw, the spectators applauding as they left the room. The Mayor: Does any other gentleman wish to speak on the proposition or move an amendment? Councillor J. R. Cocks said since the last meeting of the Council he had gone carefully into the estimates, and he could not agree with them, because he considered they were too rosy. The Mayor said he intended to have made a few remarks, but as there were no arguments to reply to he should not say anything. Alderman Dr. Shelley, after regretting that the gentlemen who had retired had not consented to alter the amendment in deference to the ruling of the Mayor, proposed that the Council adjourn for 10 minutes This was seconded by Alderman McMullen, and carried. All the members then left the court, and after an absence of nearly half an hour the whole of them (including Councillor Garratt and the others) returned. The Mayor then said that in consideration of the importance of the subject to the town, he would waive his objection, and allow Councillor Garratt to move his amendment in any form he liked. Councillor Garratt adhered to the form of his amendment as already given, and Alderman Dr. Shelley replied. The amendment was then put and lost by eleven votes against seven. The original resolution was then put, and the numbers were equal—viz., nine each The Mayor: The numbers being equal, I unhesitatingly give my casting vote in favour of the resolution. The resolution for adopting the electric light was accordingly carried, as were also subsequent resolutions giving effect to it.

Taunton—The Electric Light Committee have reported to the Town Council that they considered the subject of the extensions to the electric lighting, as approved by Dr. Fleming, and they recommended that the following be carried out:

No. 2 sub-station at St. James's-street—			
Cables	£827	14	9
Cost of laying cables and making connections	123	7	5
Two 30-kilowatt transformers and switches	261	16	0
Altering building for transformers	58	10	0
Instruments and fittings	68	1	0
Incidentals	90	10	6
	£1,450	0	0
No. 3 sub-station, similar to No. 1, cellar to be constructed under the road at East-gate	1,500	0	0
Coal-shed, weighing machinery, and other works at generating station	300	0	0
New boiler, large engine, dynamo, and other works	1,750	0	0
	£5,000	0	0

The committee recommended that application be made to the Local Government Board for their sanction to the borrowing of £5,000 for the foregoing works, to be repaid within a period of 35 years. Councillor Potter, who moved the adoption of the committee's recommendations, said he wished for many reasons that that task had not devolved upon him, as the Council were very reluctant in sanctioning the application of any committee for additional loans. It was no new experience in electric light undertakings, however, to require additional capital. Bristol, for instance in 1893 secured the loan of £66,000 for the purpose of electric lighting, and within 12 months afterwards they had to apply for another £24,000, which they duly received. At Taunton, however, they did not ask for such a large amount as that; they only asked for the modest sum of £5,000, and the whole of that they did not ask for at the present time. All they wanted was to raise £2,000 as speedily as possible, and with that they proposed to form a second sub-station, besides erecting a coal-shed and providing for other works at the central depôt, the whole of which amounted to £1,750. The balance between that sum and the £2,000 they would put to the £900 they had in hand and devote that money to laying the cables underground in compliance with the regulations of the Board of Trade. The present system of sub-stations had given entire satisfaction so far to the customers, and it had economical advantages which could not be over-estimated. It was very satisfactory to know that the extension of their business necessitated a calling up of more capital to work it. When they took over the light there were 1,000 lamps in use, and now there were 1,800, and he would be very much surprised if that number did not increase in a short time by 200 or 300. At present there was a large number of people asking for the light and waiting for it, and they had not a single transformer in stock for the purpose. When the first sub-station was formed it put 17 transformers out of use, all of which had since been taken up. It was proposed that the second sub-station should be formed in a cottage at the end of St James's-street. They could rent the cottage for 21 years at £10 per annum, and sublet it to one of their employés at £7 a year, and in it they could place two large transformers, which Messrs. Newton were to supply, and from it certain underground mains would be laid. They would clear away the overhead wires from the station, along Station-road, Bridge-street, North-street, around the Parade, and part of Cheapside, and replace them with the underground cables. No. 3 sub-station would be deferred until a time when the increased custom would testify the expenditure. In conclusion, Councillor Potter hoped the Council would do nothing to retard the progress of the work. Councillor Perkins failed to understand why the committee asked for £5,000 if, as Mr. Potter said, they only wanted £2,000 at once, but on being told it was to obviate the necessity of a second application and also that the money would only be raised as occasion required, he accepted the explanation. Alderman Standfast opposed the motion, and asserted that the Council were being misled. He said that if the whole of the extra 300 lights were really taken it would not justify them in spending another £5,000. The deficit on the working of the light was a large sum up to the present. They had already taken £660 out of the rates for that purpose, and they were asking for another £440, whilst not a penny was put down for depreciation, which would be about a thousand pounds a year. He

Digitized by Google

sincerely hoped that the Local Government Board would not sanction the loan. The Mayor pointed out that Mr. Norris, the borough accountant, had estimated the loss on the electric light for the first year at £300, the rest being caused by paying off capital and interest. Alderman Chapman said the loss was certainly not so great as some seemed to think, especially as they had another quarter's income due to them. Councillor Lock said it was no new experience on the part of the Council to find they had to pay pretty dearly for their experiments, and he predicted that this £5,000 would not be the last loan that would be asked for. However, the money had to be obtained somehow, and he would accordingly vote for the motion. The ratepayers had not pluck enough to put forward anyone to oppose the purchase of the works at the last election, and therefore they should be prepared to pay the expense. Councillor Steevens expressed his belief that ere long the electric light business would more than pay its way. Alderman Standfast: Not in your time. Councillor Potter said few sane people supposed that the undertaking would pay the first year. There was only one way to make it pay in subsequent years, and that was by having adequate machinery and by an increase of trade. The more current they produced the cheaper they could produce it, as the cost of management, etc., would remain the same. The motion proposed by Mr. Potter was then put, and carried by 17 to 1.

PROVISIONAL PATENTS, 1894.

SEPTEMBER 10.

17180. **Improvements in electric arc lamps.** Rudolf Hermann Jahr, 47, Lincoln's-inn-fields, London.

SEPTEMBER 11.

17235. **Improvements in electrical incandescent lamps.** Gerard Leonard Frederik Philips, Eindhoven, Holland.

17281. **An improved transmitter or transformer for electric currents.** William Joseph Still, 4, South-street, Finsbury, London. (Complete specification.)

17284. **Improvements relating to the transformation and distribution of electric currents.** James Finney McElroy, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

17296. **Improvements in armatures for dynamo-electric machines.** William Robert Lake, 45, Southampton-buildings, Chancery-lane, London. (Rudolf Eickemeyer, United States.) (Complete specification.)

17297. **Improvements in armatures for dynamo-electric machines.** William Robert Lake, 45, Southampton-buildings, Chancery-lane, London. (Rudolf Eickemeyer, United States.) (Complete specification.)

17313. **Improvements in and relating to electric motors.** John Samuel Losch, John Huy Phillips, Joseph Winfield Moyer, and John Harrison Williams, 77, Chancery-lane, London. (Complete specification.)

SEPTEMBER 12.

17335. **Improvements in the methods of electrically governing the voltage of dynamos and speed of engines.** Jesse Graham and Harry Chapman, Sunbridge-chambers, Bradford.

17353. **Improvements in charging primary batteries.** Samue Miller and Charles James Grist, 20, Gracechurch-street, London.

17357. **Improvements in arc electric lamps.** Samuel Sealy Allin and William Henry Wood, 25, Garlick-hill, London.

17365. **Improvements in clamps for raising and lowering electric or oil floor standards, also applicable for table lamps, music stands, and the like.** Robert Walter Braham, 60, Red Lion-street, Clerkenwell, London. (Complete specification.)

17369. **An improvement in secondary voltaic batteries.** Ludwig Epstein, 28, Southampton-buildings, Chancery-lane, London.

17378. **Improvements in direct-current transformers.** Alexander Bewicke Blackburn and Thomas Large Boyden, 47, Lincoln's-inn-fields, London.

17379. **A safety device for electrical elevators or cranes.** Benjamin Willcox, 47, Lincoln's-inn-fields, London. (The Eisenwerk vormals Nagel and Kaemp Actien Gesellschaft, Germany.)

SEPTEMBER 13.

17445. **An improved electromagnetic friction clutch.** Walter Charles Bersey, 53, Chancery-lane, London.

17447. **Improvements in electrically-propelled vehicles.** Walter Charles Bersey, 53, Chancery-lane, London.

SEPTEMBER 14.

17498. **Improvements in or relating to electric alarm clocks.** Ernest Benest, 19, Southampton-buildings, Chancery-lane, London.

17502. **An improved electric time-signalling system and apparatus.** Percy Richard Julius Willis, 55, Chancery-lane, London. (Walter Aloysius Purcell, United States.)

17510. **Improvements in or relating to electro-depositing apparatus.** Henry Le Roy Bridgman, 323, High Holborn, London.

17525. **Improvement in laying electric conductors and in forming branch connections therefrom.** Joseph Alexander Jeckell, 46, Lincoln's-inn-fields, London.

17529. **Improvements in telephone receivers, transmitters, and silent closets.** Frederick Herbert William Higgins, 24, Southampton-buildings, Chancery-lane, London.

17542. **Improvements in the construction of the lead lining or casing of cells or boxes of electric storage batteries.** John Evelyn Liardet, 9, Warwick-court, Gray's-inn, London.

SEPTEMBER 15.

17566. **Improvements in electrodes chiefly designed for use in electric accumulators and other electric apparatus.** Wilhelm Schäfer and Arthur Heinemann, 11, Southampton-buildings, Chancery-lane, London.

17572. **Improvements in electrical switches.** Herbert George Keeble, 10, Coleman-street, London.

17588. **Improvements in cables or conductors for electrolytic and other purposes.** John Leith, 6, Lord-street, Liverpool.

SPECIFICATIONS PUBLISHED.

1893.

17189. **Electric switches.** Munro and McFarlane.

19688. **Electrical decomposing apparatus.** Richardson.

19765. **Electric switches.** Durward.

19791. **Electrolytic cells.** Hurter and others.

19934. **Electricity meter.** Abel. (Compagnie Anonyme Continentale pour la Fabrication des Compteurs à gaz et autres Appareils)

1894.

1164. **Armatures of dynamos and electric motors.** Pean and Lowndes.

12345. **Electrical transformers.** Wright.

13405. **Induction coils.** Cheetham and Brown.

13995. **Electric railways.** Thompson. (McLaughlin.)

14240. **Electrical call apparatus.** Wilke.

14290. **Electrical lampholders, etc.** Binswanger.

NOTES.

Telephony in Russia.—A long-distance telephone has been established between Odessa and Nicholajew.

Madras.—The Madras Government has sanctioned a revised estimate for lighting the Arkonam Station by electricity.

Telephony in Austria.—A telephone line has been established between Brünn, the capital of Moravia, and the fortified town Olmütz.

Exhibition Lighting.—The exhibition of colonial products and manufactures now being held in Manchester is lighted by electricity.

Telephony in Hungary.—The Arad-Csanáder Railway Company have established telephonic communication between all their stations.

Electric Lighting in Holland.—The new station at Flushing adjoining the landing-stage has now been opened. It is lighted throughout by electricity.

Electric Light in Downing-street.—During the recess the electric light is being introduced into the Government offices in Downing-street.

Electric Traction in France.—Mr. E. Faye, who is connected with the Dijon tramways, has obtained a concession for electric tramways at Besançon.

The Berlin Exhibition of 1896.—The electric lighting of the Treptow Park will be carried out by the Elektricitäts-Gesellschaft Nieder-Schönweid.

Electric Lighting in Spain.—Schemes are being projected for the electric lighting of Orense, Allariz, Ginzo de Limia, Villafranca del Vierzo, Puenteáreas, and Lago.

Electro-Chemistry in Germany.—Among the applications of electricity to chemistry in Germany is, says the *Chemiker Zeitung*, that of the concentration of sulphuric acid.

Exhibition at Graz.—Under the auspices of the Austrian Minister of Commerce, an exhibition has been opened at Graz to show the advantages of electric motors in small industries.

Electric Traction in Spain.—A concession has been granted to Messrs. José Carbonnel and Busca for a narrow-gauge electric tramway connecting Barcelona with Sarria, Gracia, San Gervasio, San Martino, and San Andrès.

The Pacific Cable.—Mr. Hepworth Mercer, of the Colonial Office, and Mr. Sandford Fleming engineer of the Canadian Pacific Railway, have left London together on business connected with the projected Canadian-Australian submarine cable.

Electro-Harmonic Society.—It may be as well to remind our readers that the first smoking concert of the season will take place this (Friday) evening at St. James's Hall Restaurant, Regent-street, W. The concert commences at 8 p.m.

The Hampstead Central Station.—This central electric light station, belonging to the Hampstead Vestry, and situated in Lithos-road, Finchley-road, is to be opened on Monday evening next. Mr. R. Hackworth will switch on the light at 8. p.m.

Electric Lighthouse.—It is announced that the Yeu Lighthouse, Vendée, is to be lighted electrically. The South Wales engineers have been visiting Cornwall, and among the places inspected was the electric generating station for the light at the Lizard lighthouse.

New Dynamo Brushes.—The firm of Messrs. Schniewindt, of Neuenrade, Westphalia, have brought out a new system of wire dynamo brush, in which the finest wire that can be manufactured is used. There are said to be 13,000 wires to the square centimetre.

Telephony in Italy.—The Ministry have approved of the establishment of telephonic communication between Rome, Genoa, and Turin, Turin and Milan, Milan and Venice, and Rome, Florence, and Venice. Negotiations are also in progress for connection with Switzerland, Germany, and Austria.

Glasgow Technical College.—The Glasgow and West of Scotland Technical College Electrical Engineering Laboratory has just received an addition to its testing apparatus in the shape of a Siemens low-resistance bridge, which is capable of indicating resistances to the one-millionth of an ohm.

Rather Late.—The *Daily Chronicle* on Friday last discovered that Paris and Madrid were to be connected telephonically, and that on the Spanish side the wires have already reached Saragossa, and the line from Paris has gone as far south as Tarbes. We gave all this information in a note as far back as the 7th inst.

French Jocosity.—The following is a sample of French humour:—A gentleman enters a telegraph office: "I beg pardon, but as I was coming along this afternoon I saw myriads of flies settled on your wire. Can you suggest any explanation?" "About what time was it, sir?" "About four o'clock." "Ah, that accounts for it; that is the time I send quotations for sugar and honey."

Electric Lighting in Italy.—The new International Lyric Theatre in Milan is lighted by means of 2,400 incandescent lamps. Engineer De Benedetti, of Milan, has sent in to the syndic of Naples a request for a concession to establish a supply of the electric light, offering a reduction on the charges fixed by the existing gas and electric lighting companies. The subject has been referred to a committee for consideration.

The Antwerp Exhibition.—Correspondents are enquiring about the aerial castle at the Antwerp Exhibition. It is there, but one has to find it; and when discovered, its position is about 3ft. from the ground. The French are rather nasty about it. Some refer to it as *le ballon déchirable* instead of the *ballon dirigeable*. This is almost as bad as calling the proposed Atlantic-Mediterranean canal the *canal des deux mères*.

"Medical Battery" Company.—The Creditors' Committee of the "Medical Battery" Company, Limited, have issued a circular stating that as a difficulty has arisen in carrying out the reconstruction scheme, they are desirous of laying the matter before the creditors. A meeting for this purpose was convened for yesterday. As we stated some time ago, we hope the scheme will fall through if it is intended to conduct the business in the future as in the past.

Gas-Engines for Electric Lighting.—Mr. J. H. Killey, of Hamilton, Ontario, suggests in the *Canadian Engineer* that as in the United States a gas company are using a 300-h.p. gas-engine to run a dynamo, thereby enabling them to supply the electric light (in addition to gas-light) at a net cost far below that of the most economical steam-engines and boilers, it might prove advantageous to employ gas-engines up to 2,000 h.p. or 3,000 h.p., using Dowson gas in connection therewith.

American Institute of Electrical Engineers.—The last number of the *Transactions* of this institute to hand contains a paper on "Alternating Currents and Fuses" by Profs. D. C. Jackson and R. J. Ochsner, read in May last; a paper by Dr. F. Bedell and Mr. Carl Kinsley, entitled "A Study of the Residual Charges of

Digitized by Google

Condensers and their Dependence upon Temperature," read on the 19th inst.; and "The Electric Brake in Practice," by Mr. E. A. Sperry, read on the same date.

Telephony in Luxemburg.—In comparison with its population, the Grand Duchy of Luxemburg is very prominent in the utilisation of the telephone. According to the last official report there are 1,313 telephones in the Duchy, of which 680 are in the town of Luxemburg. All the towns, and even villages, are connected with each other telephonically. In the chief town the service is continuous both day and night. The annual subscription is £3. 2s., which entitles the subscribers to connection with any part of the Duchy.

Electric Transmission in Germany.—The Elektricitäts-Gesellschaft of Frankfort-on-the-Maine have acquired a large site near Plettenburg in order to erect a central station for the electric transmission of power to Lüdenscheid, Plettenburg, Werdohl, and Herscheid. It is also intended to light the streets by electricity, and to supply current to an electric tramway. At Metzingen a project has been brought forward for electric transmission of power in connection with the existing central electric lighting station.

Telegraphy to the Cape.—The *Times* of yesterday states that the Government of Cape Colony are moving for cheaper inland telegrams, and negotiating for cheaper cables, and that there was reason to hope that Sir John Pender would meet them in the matter. Mr. French, the Postmaster-General, is coming to England to negotiate with the cable company and her Majesty's Government on these matters, as well as with regard to the entrance of the colony into the postal union, which, he hoped, would be accomplished on January 1.

English Telephone Lines.—A trunk telephone line in connection with the London and South of England Exchange has been opened between Exeter and Exmouth. It is working most successfully, and will be of great convenience to traders. There is now communication between Plymouth, Paignton, Torquay, Dawlish, Exeter, and Exmouth, and other intermediate towns. Telephonic communication has been established between Southwold and Dunwich by means of a coast line erected along the beach between the two places. The line crosses the river at Walberswick Ferry by means of a submarine cable.

Lighting in the Metropolis.—The *Daily News* has just discovered that almost all the London districts have now made or are making arrangements for electric lighting, and that most of them have decided to institute a municipal supply. Battersea is the last parish to consider the question. It has consulted electrical engineers, and received reports from them. It has also received notice from three electric lighting companies of their intention to apply for provisional orders to light Battersea. The Vestry is not prepared to undertake the work itself just yet, but it means to apply for a provisional order to keep companies out.

Overhead Railway for Berlin.—The following lucid paragraph is culled from a daily paper: "A project for a 'hanging' electric railway has been laid before the city authorities in Berlin. The railway consists of a light iron network, with iron rails supported by columns at equal distances. At the top, on the rails, within the network, run small wagons each with two axles. To each couple of these wagons hangs a passenger carriage. The line is to run from the Berlin Zoological Gardens to the Potsdam Platz. The carriages are all of one class, and a train is composed of only three carriages, each holding 40 persons.

Electric Lighting in Austria.—The Josefsstadt Theatre, which was the only one in Vienna lighted by gas, has with the opening of the present theatrical season received an electric light installation. Both auditorium and stage are lighted electrically, and there are about 600 incandescent lamps and a number of arc lamps, the latter being mainly used for stage purposes. The work has been carried out by the Internationale Elektricitäts-Gesellschaft. The Viennese Municipality have decided to extend the electric light installation in the Rathhaus. At Budapest the local authorities will light electrically the Redoubten Halls, a pleasure resort, at a cost of about £4,000.

Canadian Electrical Regulations.—The Canadian Parliament has just passed an Act providing for the inspection of electricity meters. This Act allows consumers, whenever they are dissatisfied with the action or tests of the electric light contractors, to have their wires and fittings tested by an electric light inspector upon application to the Inland Revenue Department, which has charge of the inspection under the Act. The Act also settles a question upon which there was formerly no written law in providing that any person discovered maliciously or fraudulently abstracting, or causing to be wasted or diverted, any electricity, shall be dealt with as guilty of theft, and punished accordingly.

Finsbury Technical College.—The autumn courses of lectures and laboratory work at this technical college begin next week. On Mondays, Prof. Silvanus Thompson will deal with alternate currents through the month of October, and in November will give four lectures specially upon modern alternate-current motors. The Wednesday evening lectures (elementary course), after the introductory discourse on October 3 by Prof. Thompson, will be taken by Mr. Eustace Thomas until November, when Prof. Thompson will take up measuring instruments. The laboratory course remains, as heretofore, under the charge of Mr. E. A. O'Keefe. The electroplating laboratory class under Mr. Rosseau will meet later in the session. Prof. Thompson's special course of lectures on "Central Stations for Electric Lighting" are to be given on Thursdays at 7.30 p.m., commencing October 4. Particulars of all these courses are to be obtained from the college registrar.

Telegraphic Delays.—At a meeting of the council of the Liverpool Chamber of Commerce on Wednesday, Mr. Hemelryk called attention to the delays in telegrams between Liverpool and the Continent, and to the stereotyped explanation of the Post Office that these were due to the "wires working badly." He believed that the postal authorities, in fact, did not take the trouble to enquire into the matter, inasmuch as some years ago, in the late Postmaster-General's time, complaints had been made and the matter had been remedied. Now, however, the delays had recommenced. He therefore moved that a deputation should be appointed to wait on the Postmaster-General. He believed the chief blame to rest on the shoulders of the foreign telegraph offices; at any rate, it was absurd that from a thousand miles away they could get a reply in half an hour, whilst from only a few hundred miles a reply came in five or six hours. A deputation was appointed as proposed.

Electrical Conductivity of Salts.—Mr. B. Völlmer, in *Ann. Physikal. Chem.*, gives the following: The conductivities of the acetates and iodides of sodium and potassium, and of lithium chloride, dissolved in ethylic and methylic alcohols were measured, as also those of the chlorides of sodium and calcium and the nitrates of silver and calcium, dissolved in ethylic alcohol. The molecular conductivities increase with increasing dilution, and approach a limiting value for infinite dilution, except in

Digitized by Google

the case of calcium chloride and of calcium nitrate. The limiting values for the molecular conductivities in methylic and ethylic alcohol solution may be obtained from those in aqueous solution by multiplication with a factor, in the first case about 0·73, and in the second about 0·34. It appears, therefore, that the conductivity decreases with the rising molecular weight of the solvent. The temperature coefficients increase with rising dilution, and for very dilute solutions the conductivity coefficients are practically the same as those for the viscosity of methylic and ethylic alcohols. Ostwald's dilution law is not applicable to the solutions examined, and from the conductivities it is not possible to calculate the rise in the boiling point of ethylic alcohol in its solutions, as it is with water.

Electric Traction in Germany.—Official tests have been satisfactorily carried out on the Heckinhauser electric tramway, Barmen, and the line has been opened to the public. The electric cars which are being built for the Grosse Berlin Horse Tramway Company are to be started running by the middle of next month on the line between Leipziger Platz and Moabit. For years a railway on the Wartburg has been spoken of, and now the project has come up again. No decision has been come to as to the method of traction, but electricity will probably be adopted. The agreement with Messrs. Siemens and Halske for an elevated electric railway in Berlin will shortly be concluded. Steps are also being taken in connection with the electric tramway which the same firm propose to construct in Berlin between Gesundbrunnen and Pankow. The Grosse Berliner Horse Tramway Company are experimenting on their lines with accumulator cars. The accumulators have been supplied by the Hagen accumulator works, and their weight per car is 66cwt. In connection with the proposal to construct an electric tramway between Barmen and Schwelm, the principle of the scheme has been approved by the local authorities of the latter place. It is proposed to connect the line with the Heckinghauser tramway.

Electric Lighting in Bombay.—In accordance with a recent resolution of the Bombay Municipal Corporation, the Crawford markets have been fitted throughout with an electric light installation by Messrs. John Fleming and Co. The system, which has been fitted up under the supervision of Mr. Hoar, one of the firm's representatives, consists of some 20 large Brockie-Pell arc lights and about 60 incandescent lights. The former are distributed throughout the markets and the grounds and front of the building, while the smaller lamps are used as a means of illuminating the tower staircase, the superintendent's quarters, and the clock faces. Both circuits are fed by dynamos placed in the municipal workshops at Paltan-road, the current being conveyed to the lamps by means of armoured underground cables. The dynamos, which are of the Silvertown pattern, are capable of being driven respectively at 850 and 1,000 revolutions per minute, each dynamo being controlled by an elaborate switchboard, by which the power passing over the lines can be measured and adjusted. Alongside these instruments is placed another machine used for the lighting of the Municipal Offices, which can be started or stopped by a friction clutch. The motive power for the several dynamos is supplied by a large engine and boiler belonging to the Municipality.

Electric Lighting in Germany.—The Elektricitäts-Gesellschaft vorm. O. L. Kummer and Co., are largely extending their works in Dresden. The Houseowners Association of Wilhelmshaven have been discussing the question of the introduction of the electric light into the town. Messrs. Siemens and Halske have made a proposal, and circulars have been issued to ascertain the probable demand. The Municipality of Haynau have decided not to carry out the extension of the gasworks, estimated at £3,500, but simply to do repairs at a cost of £75. On the other hand, the Municipality is being asked to introduce the electric light, and an offer has been received from the Helios Company. A central electric light station has been built at Rottweil by Messrs. Feil, of Stuttgart. The water power of the Neckar is utilised, and the three-wire system is employed. It has been decided to light electrically the Neuestrasse, Brunswick. The arc lamps are to be suspended from chains fixed across the street. Current will be obtained from the electric station of Messrs. Meves and Co. The Municipality of Wilster have contracted with Messrs. Lahmeyer and Co., of Frankfort, to erect a central station for light and power purposes. The Municipality of Landstuhl have given permission, on the recommendation of Mr. O. von Miller, to Messrs. Bumb and Herrle and the Helios Electricity Company to establish a central station in the town. The proprietor of the Mostrich factory at Leinefeld is going to adopt the electric light, and will also supply some of the hotels with current.

Electrical Method Determining Transition Points.—Mr. E. Cohen, in the *Zeit. Physikal. Chem.*, says that if a voltaic element be formed by the immersion of similar electrodes in saturated solutions of the two forms of a substance capable of undergoing a transition change, then at temperatures above or below that of the transition the current will flow in opposite directions, becoming nil at the transition temperature itself. This forms the basis of the method; such an element being placed in a thermostat, and the current measured at various temperatures, the null point being carefully determined. Details of the method and of the mode of preparing the element and the electrodes are given in the paper. The method is applicable to transition changes due to loss of water of crystallisation, formation of double salts, double decomposition, and polymorphism. The following changes are examined and the temperature determined:

(1) $Na_2SO_4,10H_2O \rightleftarrows Na_2SO_4 + 10H_2O$. t = 32·8deg.
(2) $CdCl_2,2H_2O \rightleftarrows CdCl_2,H_2O + H_2O$. t = 34·1deg.
(3) $ZnSO_4,7H_2O \rightleftarrows ZnSO_4,6H_2O + H_2O$. t = about 42deg.
(4) $Na_2SO_4,10H_2O + MgSO_4,7H_2O \rightleftarrows Na_2MgSO_4,4H_2O + 13H_2O$. t = 20·8deg.
(5) $2MgSO_4,7H_2O + 2NaCl \rightleftarrows MgNa_2(SO_4)_2,4H_2O + MgCl_2,6H_2O + 4H_2O$ (good results were not obtainable).

The author points out that the method has the advantages of accuracy and speed, but is only applicable to conductors, whilst for some of these the preparation of the electrodes is a matter of very great difficulty. The paper concludes with a consideration of the method from the thermodynamical standpoint, the fundamental equation

$$E = W + T\frac{dE}{dt},$$

being applied for this purpose.

Austrian Electrical Trades.—A few weeks ago we referred to the reports issued by a Berlin commercial society regarding the condition of the electrical industry in Germany. Since then a similar report has been prepared by the Vienna Chamber of Commerce, and has been presented to the Ministry of Commerce. This report, which is for the year 1893, states that the central station of the Internationale Elektricitäts-Gesellschaft was favourably developed during that year, that the station was enlarged, and that its capacity had been increased to 4,000 h.p. The number of incandescent lamps connected to the mains had advanced to 70,000 and of arc lamps to 800, whilst a supply of current was furnished for the operation of 31 electric

Digitized by Google

motors of powers ranging from 1 h.p. to 10 h.p. These motors are utilised not only for trade purposes, but also specially for the working of lifts. The company had assisted in the formation of a Hungarian electrical company. Extensions were also made by the Allgemeine Oesterreichische Elektricitäts-Gesellschaft, which supply current on a five-wire direct-current system. The total output of the company's station was distributed among 32,718 incandescent lamps, 1,778 arc lamps, and 57 electric motors. The second undertaking in Vienna where the direct-current system is employed is that of the Wiener Elektricitäts Gesellschaft, which at the end of 1893 supplied 21,678 incandescent lamps of 16 c.p., as compared with 13,972 at the close of the previous year. The report points out that the question of utilising electric power on the Vienna tramways had not passed out of the preliminary stage in 1893, and that the only success of the efforts put forth in this direction had been to cause the authorities to take an interest in the subject. Electrical installations had been carried out in other towns, partly by Vienna firms and partly by foreign companies, notably that at Baden, where current is supplied not only for lighting, but also for the operation of the Baden-Vöslau electric tramway.

Instructive.—At the Mansion House on Friday last, Charles S. Huelser, trading as Huelser and Co., Temple-chambers, was summoned before the Lord Mayor, at the instance of the Incorporated Law Society, for unlawfully pretending to be a solicitor. Mr. Humphreys, solicitor, who appeared for the prosecution on behalf of the Incorporated Law Society, said that the summons was taken out under the Solicitors Act, 1874. The matter complained of was a circular issued by the defendant in the form of a pamphlet, in which he described himself as "Huelser and Co., Temple-chambers, London, international patent solicitors and commission merchants." The words complained of were "international patent solicitors," and Mr. Humphreys submitted that no person could so describe himself unless he had a certificate to practise as a solicitor. In reply to the Lord Mayor, the defendant said he never intended to call himself a solicitor. The Lord Mayor asked him whether in the future he was willing to undertake to discontinue the use of the words "patent solicitors." The defendant replied that he should do it again, as he was fully entitled to do so. The Lord Mayor: In my opinion your using the words "patent solicitors" leads anyone to imagine that you were practising as a solicitor. The defendant: "Patent solicitors" is a compound word. I never attempted to practise as a solicitor. The Lord Mayor asked whether it would not be better to adjourn the case for the defendant to take the advice of friends. After some further conversation, in the course of which he repeated that he never called himself a solicitor, the defendant undertook for the future not to have the words "patent solicitors" printed on any circulars or note-paper. The Lord Mayor expressed an opinion that the covers of the circulars and the note-paper bearing the words "patent solicitors" should be destroyed. He adjourned the case. And yet there are patent agents who coolly describe their office as being "The Patent Office" without any action being taken by the government.

Telephones to Lightships.—The Rev. T. Hancocks, of Ramsgate, writes to a daily paper as follows: "My attention has been called to a statement in which Mr. Julius M. Price declares that electrical communication with lightships is a failure. Kindly insert this correction, as one fact is worth many theories. The Goodwin lightship, situated at the north end of the Goodwin Sands, is connected with the shore by telephone. No part of the planet is more perilous than this spot, and the vessel is fully exposed to what sailors call 'a breeze.' Yet for seven months the telephone has worked admirably, as my experience tends to prove. One of her crew, a member of my church, had a son critically ill ashore while his father was doing his two months on board. To relieve his anxiety I obtained permission at the coastguard station to speak the lightship. I told him the home news, had with him a general chat, and bade him good-night. I easily recognised his voice, quite as well as I ever heard one through a land telephone, and the Goodwin is over six miles from shore; also the officials assure me that the telephone is a complete success. There are only two drawbacks: (1) the chafe of cable near the ship necessitates frequent repairs—experience will soon suggest some safeguard; (2) the ship does not ride rough seas so lightly as before owing to her being anchored by four heavy chain cables instead of one. This, while no danger, is less comfortable for the crew, as she ships more seas aboard. It has been suggested that each cable should be supported by a buoy, which would probably remove this defect. But already this telephone has proved its immense value in saving precious life and valuable property. At a wreck, as at a fire, the first five minutes are worth the next five hours, and since the cable news of a ship on the Goodwins has reached land, the lifeboat has been despatched and all hands saved with a speed incredible to former times. The cable is no failure, but a thorough success."

Competition in Atlantic Telegraphy.—The following apparently inspired quotation from the *Railway News* explains itself: "Increasing attention is now directed to the probability of additional competition in Atlantic telegraphy, and, judging from the correspondence to hand, the shareholders are not quite reassured by the statement of the chairman, that the projected German line will be in 'friendly' hands. If, however, the new cable is to be laid by an independent company, the consequence must necessarily be a more or less serious diversion of business from the existing lines. It is reported that the German Government is prepared, or will at least be asked, to guarantee interest on the required capital, though it is difficult to see how German interests could be better served than by existing arrangements. The Anglo-American Company agree to hold a cable for the exclusive use of German business in connection with the Channel service, which thus has four ocean lines available as insurance against the mishaps to which cables are liable. The projected new line, which, it is said, will be laid *vid* the Azores, would not cost much less than a million sterling, and the expected return, say, of 5 per cent., on this capital would mean the abstraction of between £120,000 and £130,000 gross receipts from the existing pooled lines, involving a serious reduction of the present diminished dividends. It should surely be within the power of the supposed 'friends' of the Anglo-American Company to stop such a waste of capital and revenue. The money would doubtless be raised in this country, and the only object to be served, so far as English capital is concerned, would apparently be to develop business over the cable already laid to the Azores at the instance of the Portuguese Government. The present contract with the German Government expires in the year 1900, but it is understood that overtures will be made to terminate the arrangement at an earlier date so as to permit of the launching of the new project. The various companies said to be promoting the scheme being represented by practically identical board of directors, there should be little difficulty in preventing such clashing of interests as would be caused by the construction of the new line.'

THE ELECTRICITY WORKS AT EALING.

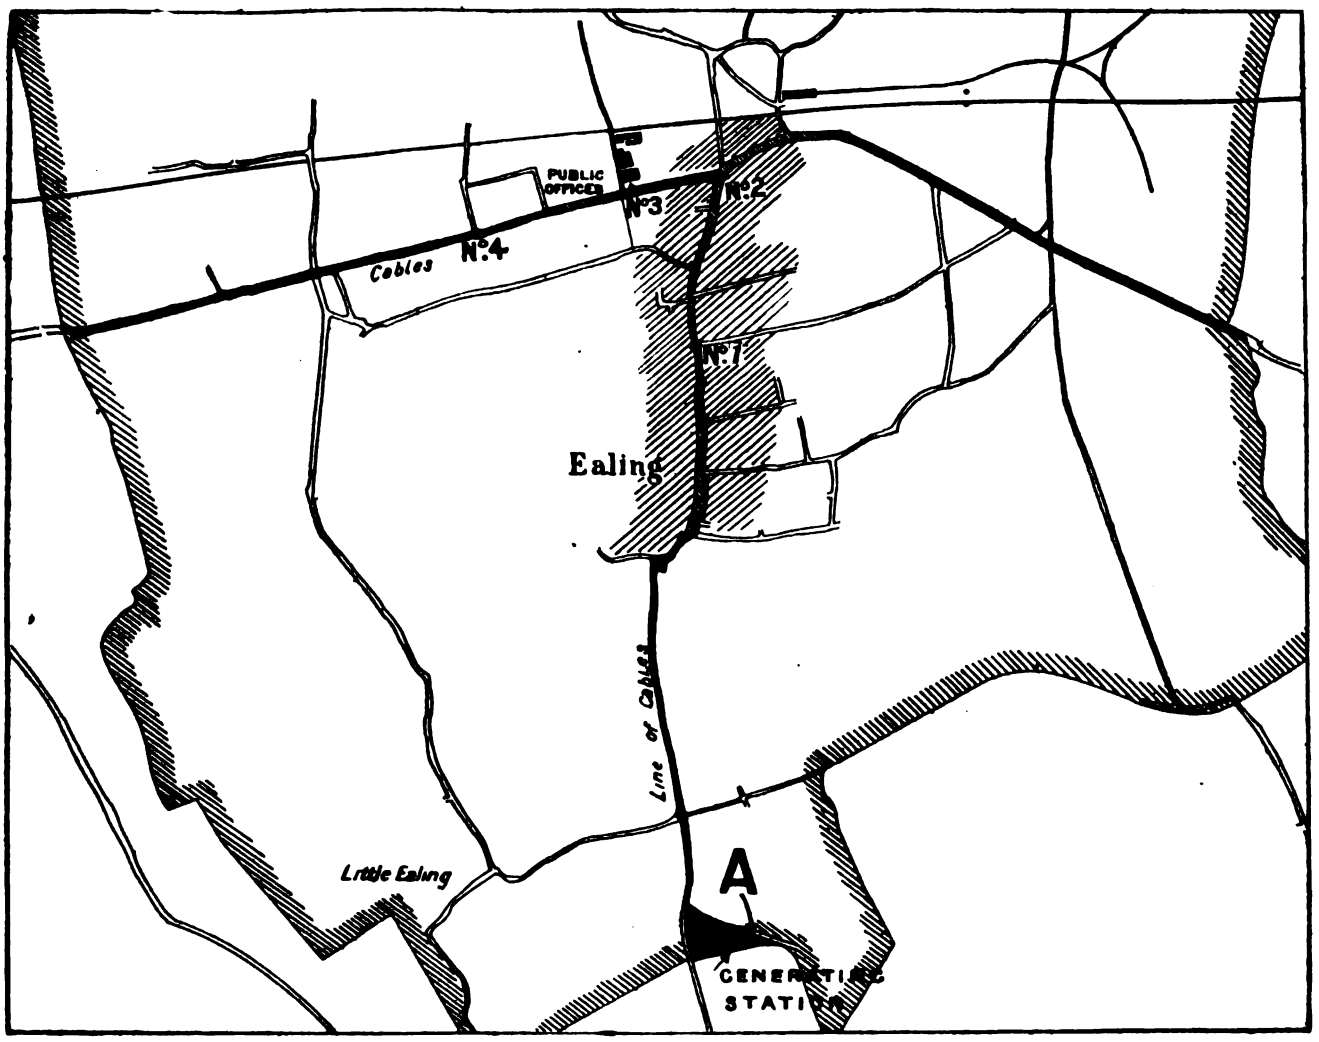
NOVEL DEPARTURE IN CENTRAL ELECTRIC LIGHT STATION PRACTICE.

General Remarks.

It is doubtful whether a more progressive and enterprising local authority could be found than that at Ealing. The Ealing Local Board was originally constituted in 1863, when the population comprised some 5,000 persons. The Ealing of that period and the Ealing of the present are entirely different. At the former date it was purely a village; there were no public gas lamps, no sewers worthy of the name, and with the exception of the main road there were no properly-formed roads in the district. At present, thanks to the successful policy of the Local Board, which on its for mation supplanted the old highway board in the above mentioned year, a complete transformation has taken place. The district is now provided with well-kept roads, with a complete drainage and sewerage system, and with gas and electric lighting, whilst the population has increased to some 27,000 souls. To Mr. Chas. Jones, M.I.C.E., engineer and surveyor to the Local Board, is due a large amount of credit for bringing the district to its present satisfactory position. The healthiness of the neighbourhood may be gathered from the fact that the death-rate is 11·3 per 1,000, this being lower than several of the best known health resorts in the country.

Ealing, together with Acton and Chiswick, constitutes the Ealing Division for parliamentary purposes. The public buildings, which are situated in the Uxbridge-road, form an imposing structure, erected from the designs of Mr. C. Jones. They include a Free Library, Science and Art School, and the Victoria Jubilee Hall, where an electrical exhibition will be opened on Wednesday next, and will be continued for 10 days. A convenient theatre is provided by the Lyric Hall in the Broadway.

The suburb of Ealing lies on the northern and southern sides of Uxbridge-road, and is about six miles distant westerly from the Marble Arch, or from the spot where criminals once met their doom at Tyburn turnpike. It is within the hundred of Ossulstone and the county of Middlesex, and in the diocese of London. Ealing is bounded on the east by Chiswick, Acton, and Twyford; on the west by Hanwell and Hayes; on the north by the River Brent, Harrow, Perivale, and Greenford; and on the south by Brentford. The district is a large one; the parish reaches two miles from north to south, and slightly over two miles from east to west, the acreage being about 3,225 acres.



Plan showing Site of Generating Station and Compulsory Area of Supply.

Historical.

A few remarks concerning the history of the district should be of interest. The horrors of war were little known in the neighbourhood of Ealing from the time of Canute down to that of the Civil War. Then an engagement took place on November 12, 1642, at Brentford, between the forces of the Royalists and of Parliament. Although this battle was not of any great extent, it resulted in much recrimination between the king and the disaffected subjects. A more terrible visitation than war occurred in 1665 and 1666, when the ravages of the plague carried off over 250 victims in 12 months.

Among the imposing buildings dedicated to divine service in the district may be mentioned St. Mary's, the parish church, which is a brick edifice built on the site of a former structure, originally erected in 1729. In addition to this there are eight other churches, besides a number of chapels belonging to various denominations. Of stately mansions there is a number in Ealing and its vicinity, these being erected in rich and spacious grounds and surrounded by

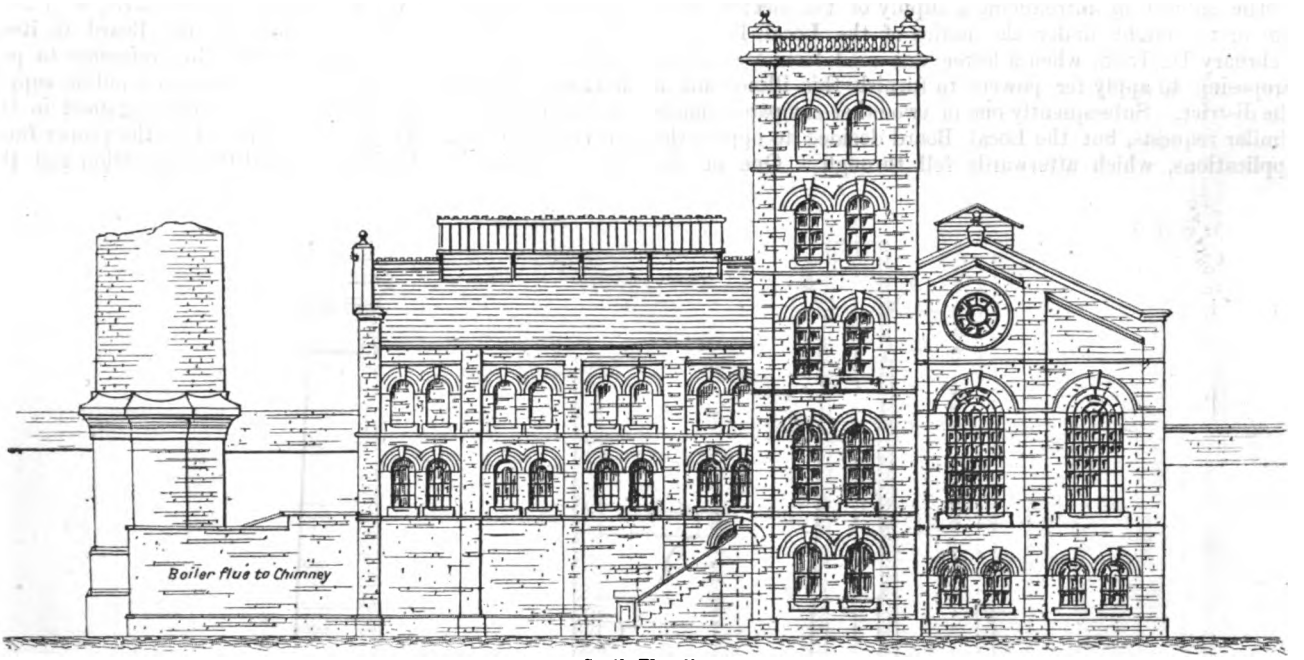
North Elevation from Occupation Road.

walks and noble trees. Castle Hill Lodge, which down to 1812 was one of the seats of the Duke of Kent, formerly stood on Castlebar-hill. This noble duke, who was the father of her Majesty the Queen, married in 1818 a princess of the house of Coburg. Amongst other notables we may mention the Earl of Rochford, the Dukes of Marlborough, Suffolk, and Argyll, Sir Francis Dashwood, the Percevals, Lord Brooke, and Lord Manners. John Horne

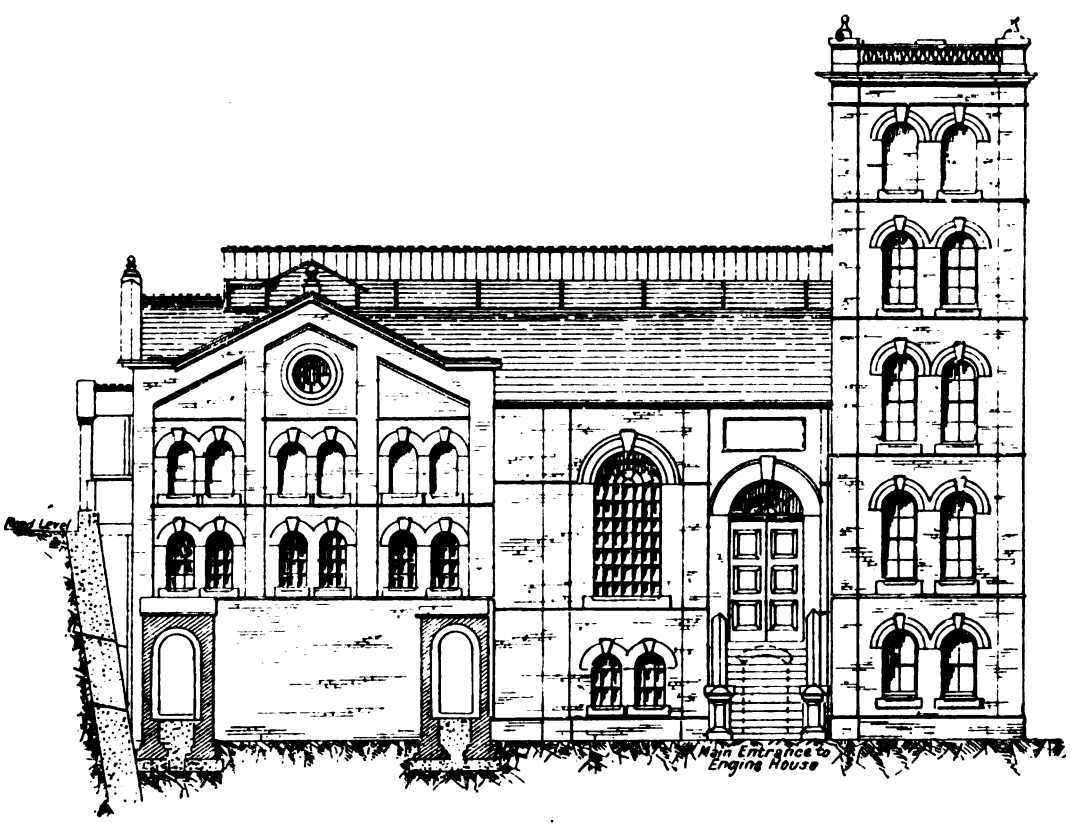
Digitized by Google

Tooke and the great political writer of the last century, John Oldmixon, were buried there. Sir William Lawrence, the eminent surgeon, died there, and was buried in the old parish churchyard. The great Lord Heathfield dwelt in the village and at "Fordhook," Henry Fielding, the novelist, and subsequently Lady Byron. In the drawing-room of "Fordhook," "Ada, sole daughter of my home and heart," was married to Lord King, afterwards Earl of Lovelace. The Right Hon. Spencer Horatio Walpole was for many years a resident, and Prof. Huxley was born in Ealing. Thackeray went to school there; Dickens often visited his sister, Mrs. Hogarth, at Ealing Dean; some of the best songs by Dibdin were written at his residence in Hanger-lane; and Edward Bulwer Lytton went to school in what was formerly known as Love-lane.

Among other notable buildings in the district may be mentioned Gunnersbury House. This historic mansion, now owned by Baron Rothschild, stands on rising ground on the outskirts of Ealing, where it borders on Turnham Green. The Grove, which towards the end of the seventeenth century was occupied by Sir William Trumbull, the friend of Pope, stands on the edge of Ealing Common. One speciality is the large private scholastic establishments; the largest private school in England—Great Ealing School—was kept for many years by the Drs. Nicholas. Probably not many private tutors could show a longer list of scholars who became men of note than could the Nicholas family, amongst others: Sir Henry Lawrence, Bishop Selwyn, Charles Knight, Sir Henry Rawlinson, Cardinal Newman, Captain Marryatt, William Makepeace Thackeray, Lord Truro, and many others. It would probably be difficult to find for the same size any district which possesses so many colleges, academies, and day schools as are to be found at Ealing, a fact which, considering the healthy condition of the locality, its proximity to the lovely haunts



South Elevation.



West Elevation.

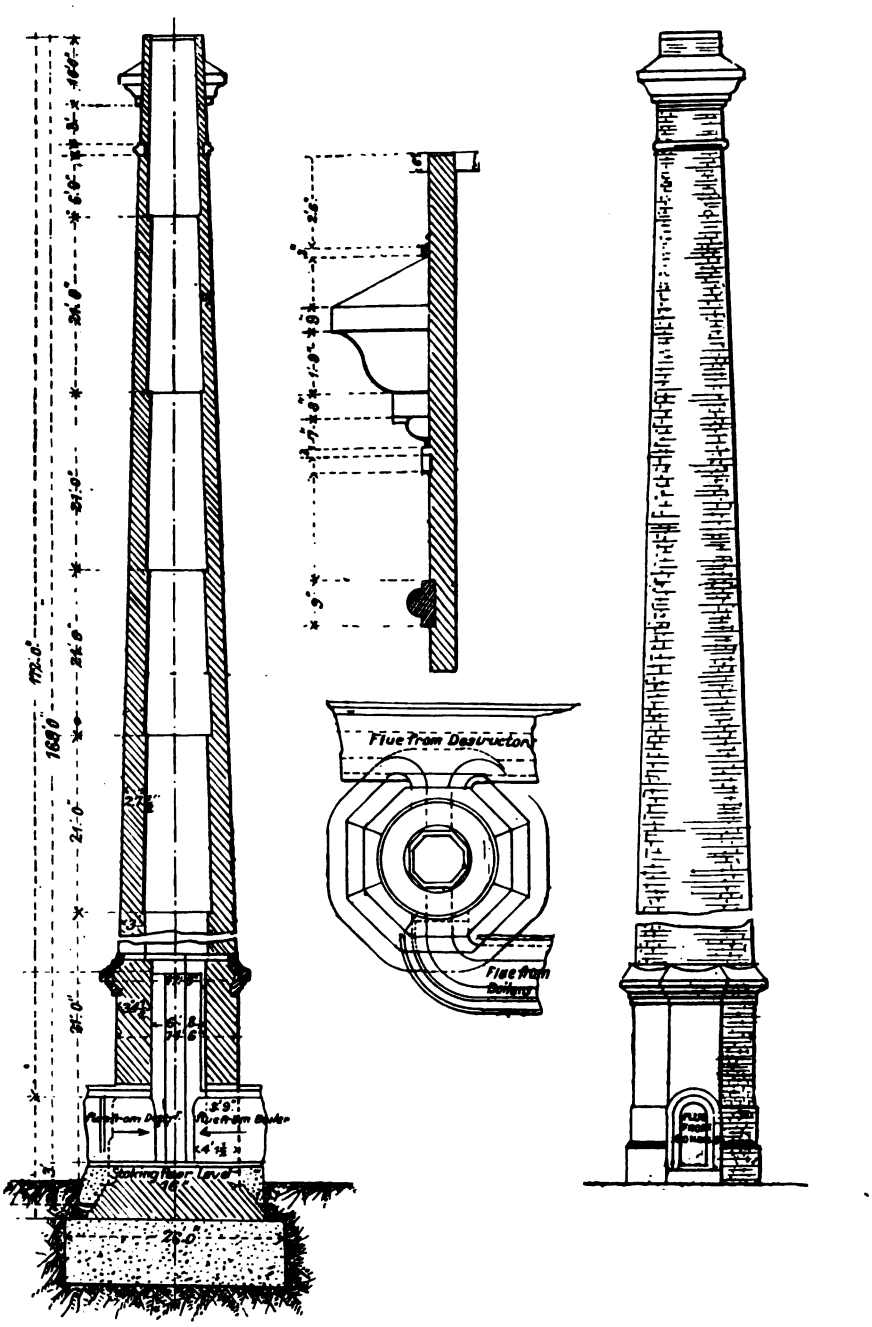
Digitized by Google

on the Thames, its many open spaces, etc., is not surprising. It is even said that there is no place in Ealing that can reasonably be called a slum. In this it differs greatly from its neighbour, Brentford.

Preliminary Steps in Electric Lighting.

The subject of introducing a supply of the electric light was first brought under the notice of the Local Board on February 16, 1888, when a letter was read from a company proposing to apply for powers to furnish this illuminant in the district. Subsequently one or two other companies made similar requests, but the Local Board decided to oppose the applications, which afterwards fell through. One of the members of the Local Board, Mr. Kasner, was the first to suggest that the Board should itself put down plant and provide a supply of electricity. On February 20, 1890, on the motion of the chairman (Mr. E. M. Nelson, J.P.), the Board unanimously decided to apply for a provisional order authorising the establishment and working of electricity works. As a result of this, a provisional order was granted to the Board in 1891.

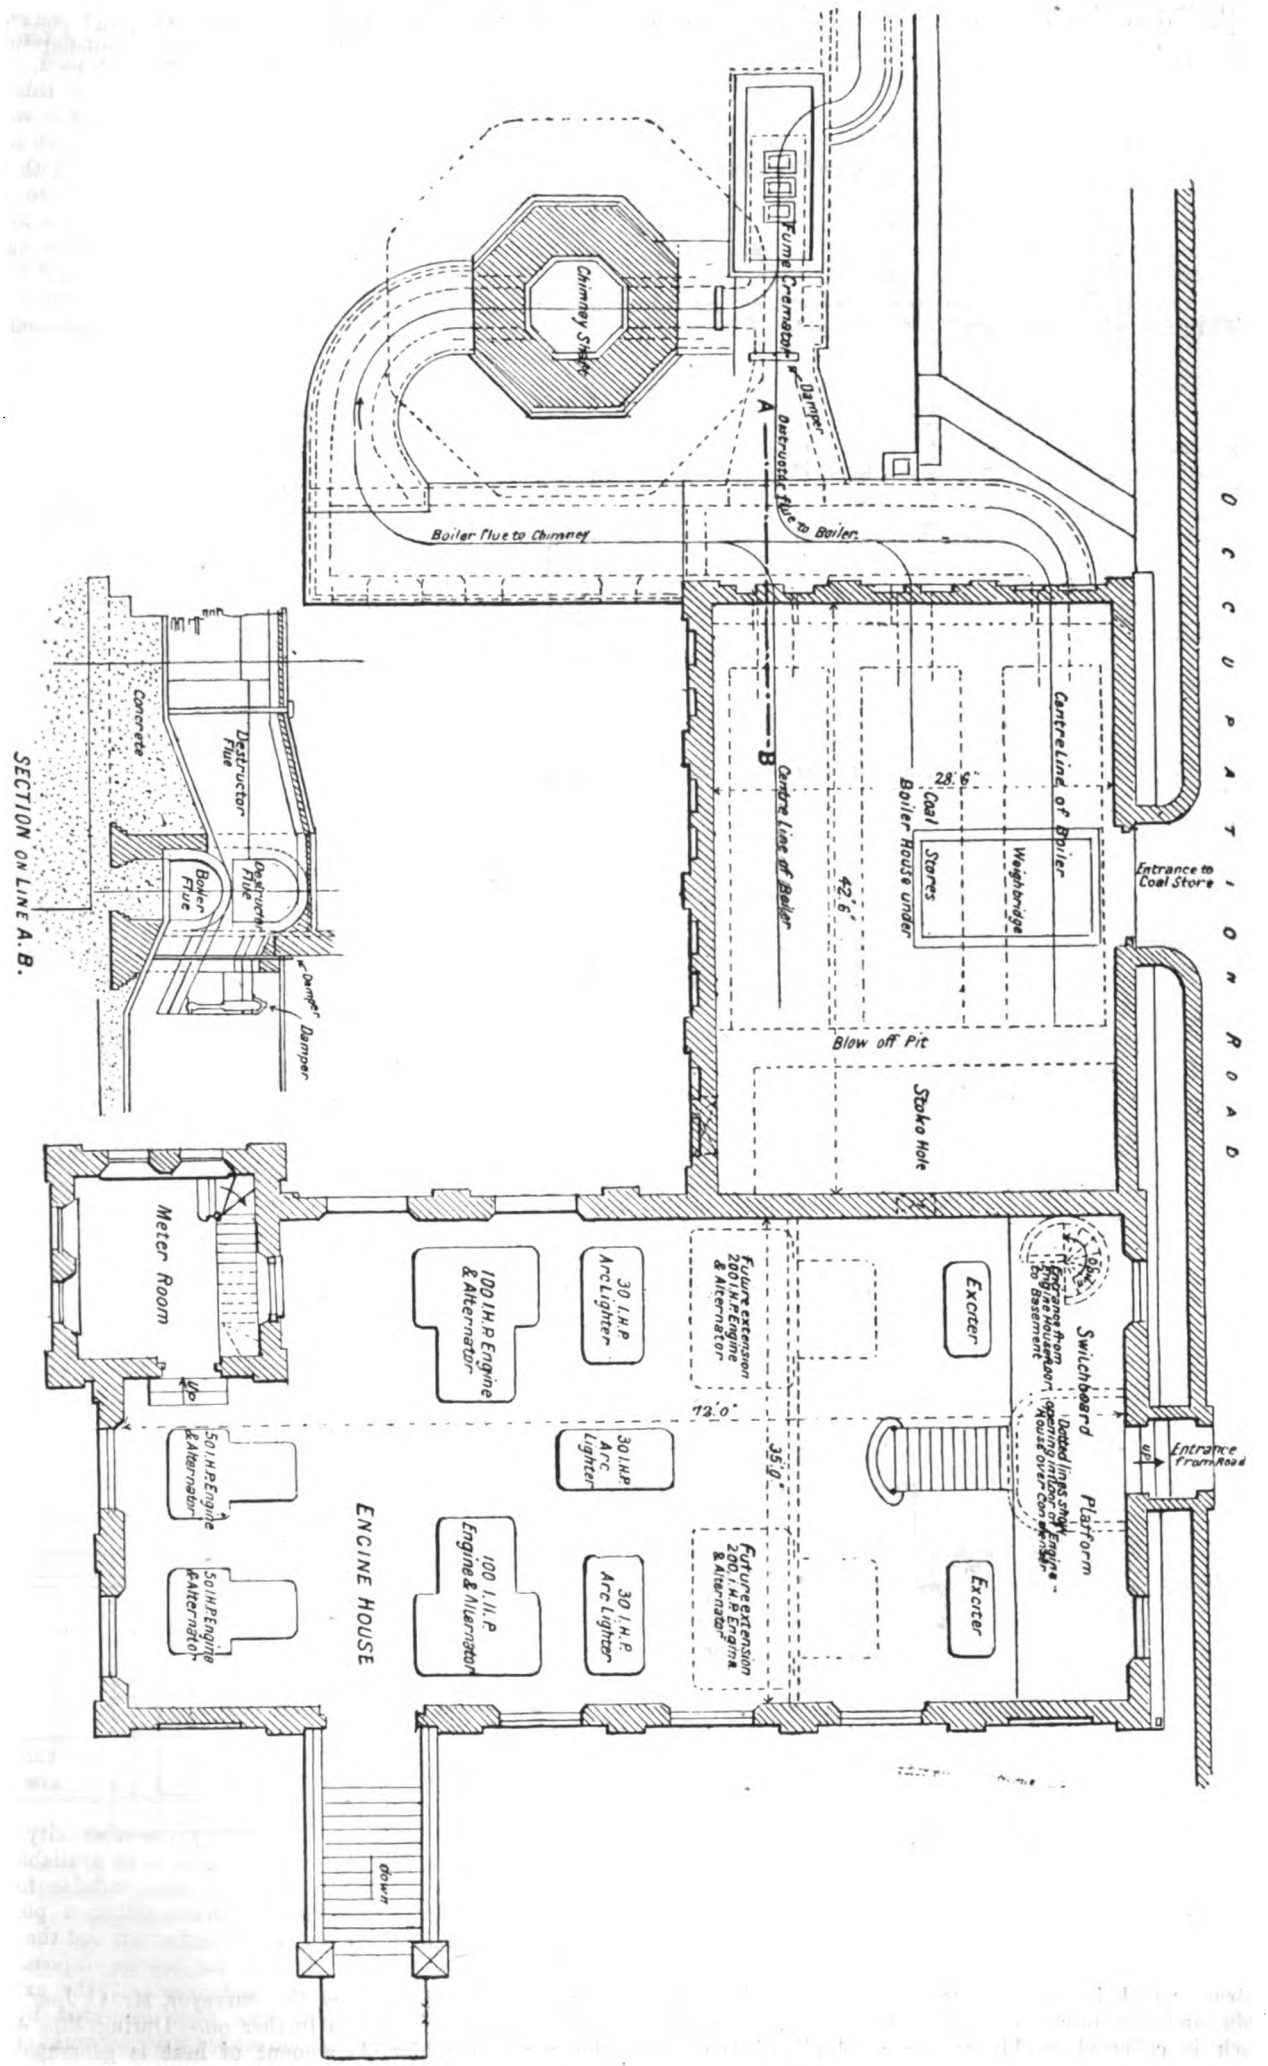
Time passed away, and in December, 1892, the Local Board instructed their engineer, Mr. Jones, to communicate with Messrs. Bramwell and Harris, asking them to prepare a report as to the advisability of introducing a supply of electricity, and as to the most suitable scheme for lighting the district in this manner. The compulsory area of supply set forth in the order may be said to have practically determined the system which it was desirable should be adopted. This will be understood when it is mentioned that this area extends the whole length of the district from east to west, a stretch of some two miles, and from north to south to the extent of 1½ miles. Messrs. Bramwell and Harris, with their characteristic enterprise, recommended the Board to itself undertake the lighting of the district in preference to permitting a company to step in and establish a public supply of electricity by the transfer of the powers contained in the provisional order. The Board, as indeed is the proper function of all local authorities, adopted this suggestion and the scheme prepared by the consulting engineers, and the result is shown by the well-equipped electricity works now being set in operation.



Section, Plan, and Elevation of Chimney Shaft.

When the question of the site for the electricity works was discussed, it was found that there were available two places owned by the Board which were suitable for the purpose. One was the Drayton Green siding, a piece of land nearly at the extreme west of the district, and the other was a plot of vacant space at the sewage disposal and destructor station, off South Ealing-road, at the extreme south of the district; both sites were inspected by the consulting engineers, who recommended that the works should be built on the latter.

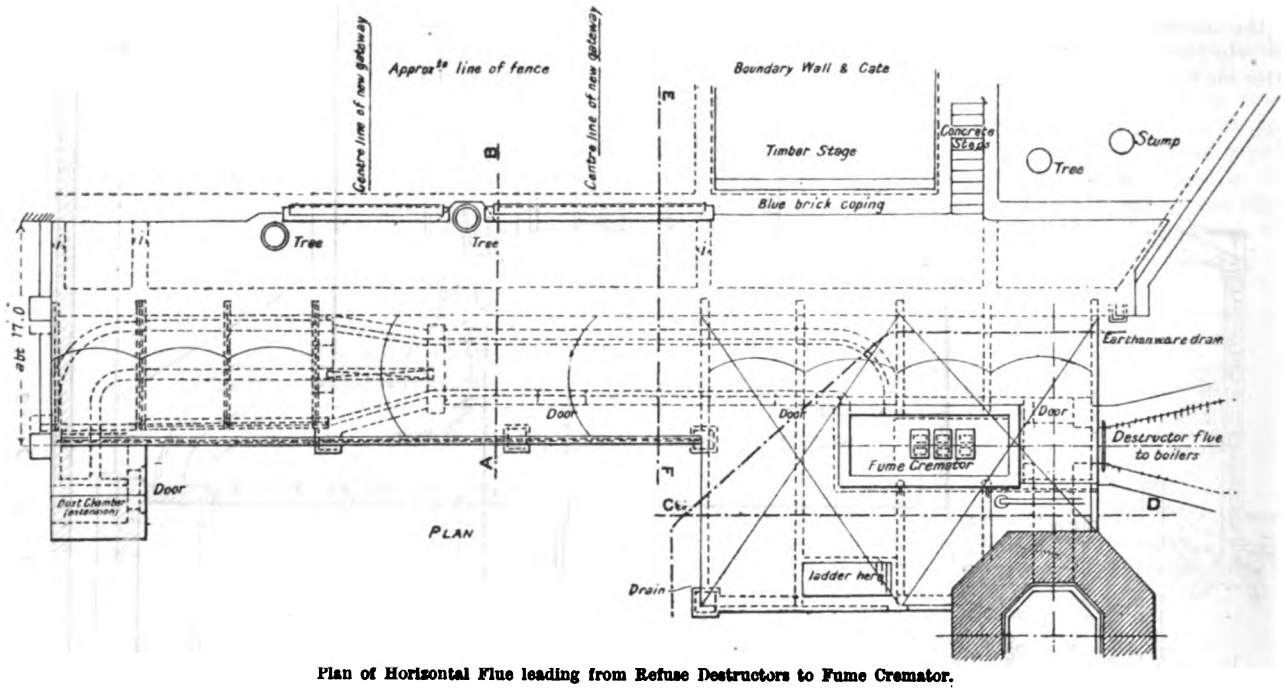
Digitized by Google



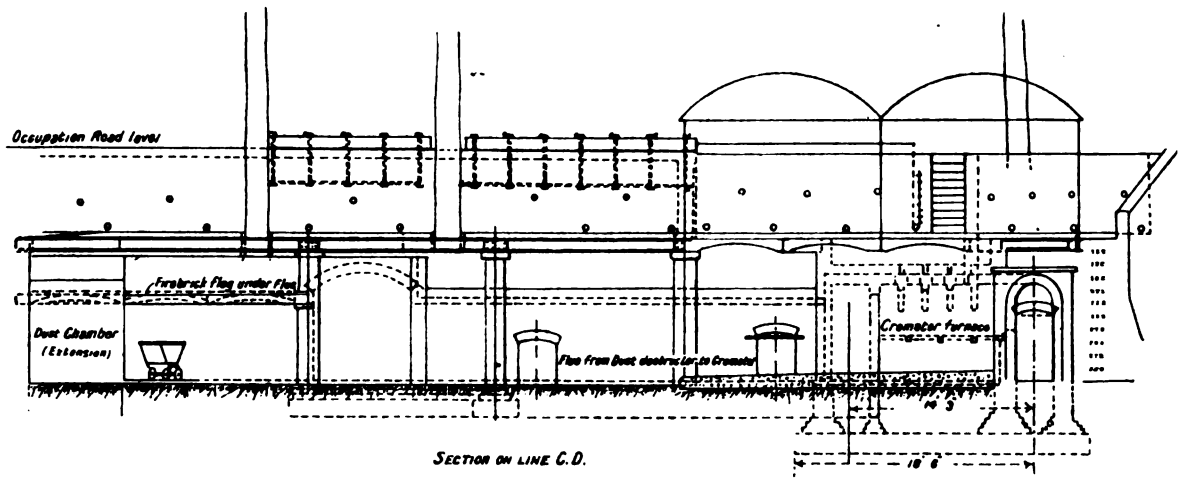
General Plan of Ealing Electricity Works.

Digitized by Google

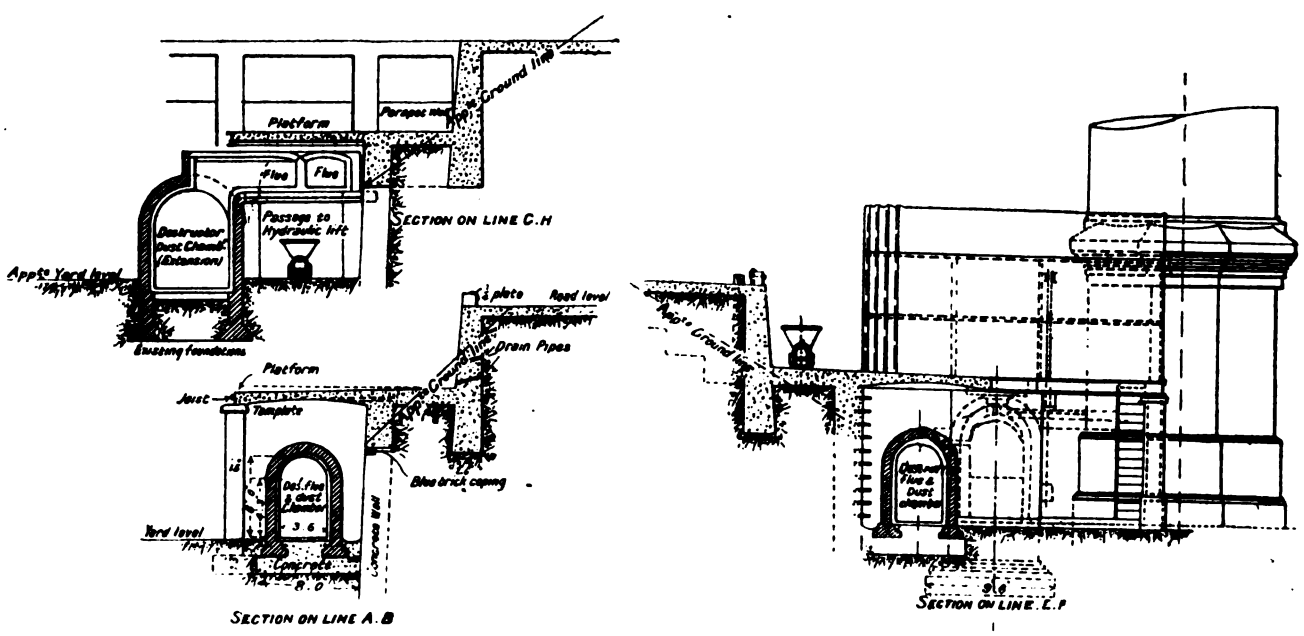
One of the reasons that led to the adoption of this suggestion was the fact that on the spot was ready at hand a lot of waste heat resulting from the incineration in a refuse Board, is conveyed to the destructor station, mixed with the sewage sludge, tipped into the destructors, and consumed. The process of destruction is practically completed by the



Plan of Horizontal Flue leading from Refuse Destructors to Fume Cremator.



Section (on line C D) of Horizontal Flue from Destructors to Cremator.

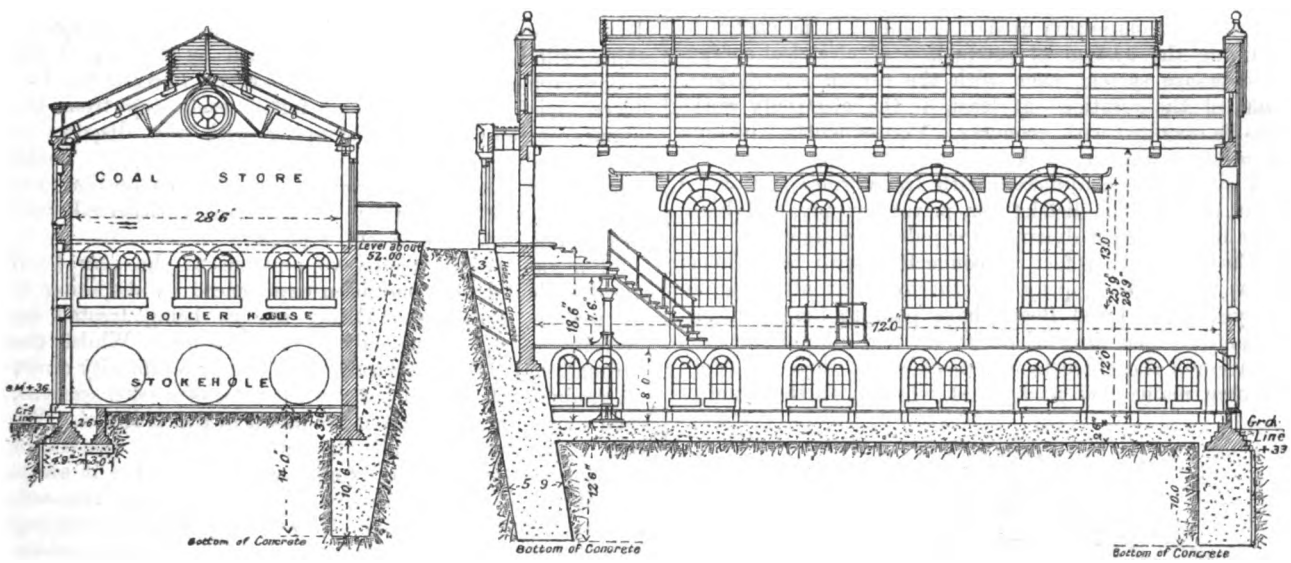


Section (on lines G H, A B, and E F) of Horizontal Flue from Destructors to Cremator.

destructor and in the "fume cremator" of the sewage sludge and dustbin refuse of the district. The latter refuse, which is collected weekly by the employés of the Local fume cremator devised by the surveyor, Mr. C. Jones, and to which reference is made further on. During this operation a very considerable amount of heat is generated. A

Digitized by Google

portion of it was already used to raise steam for the operation of the engines in the sewerage works, but a considerable quantity has hitherto passed up the chimney. It was this waste heat that the consulting engineers advised the Board to profitably utilise to assist in generating steam for the engines driving the dynamos. Another reason for the selection of this site was the question of a supply of water for the purpose of steam condensation, a matter which



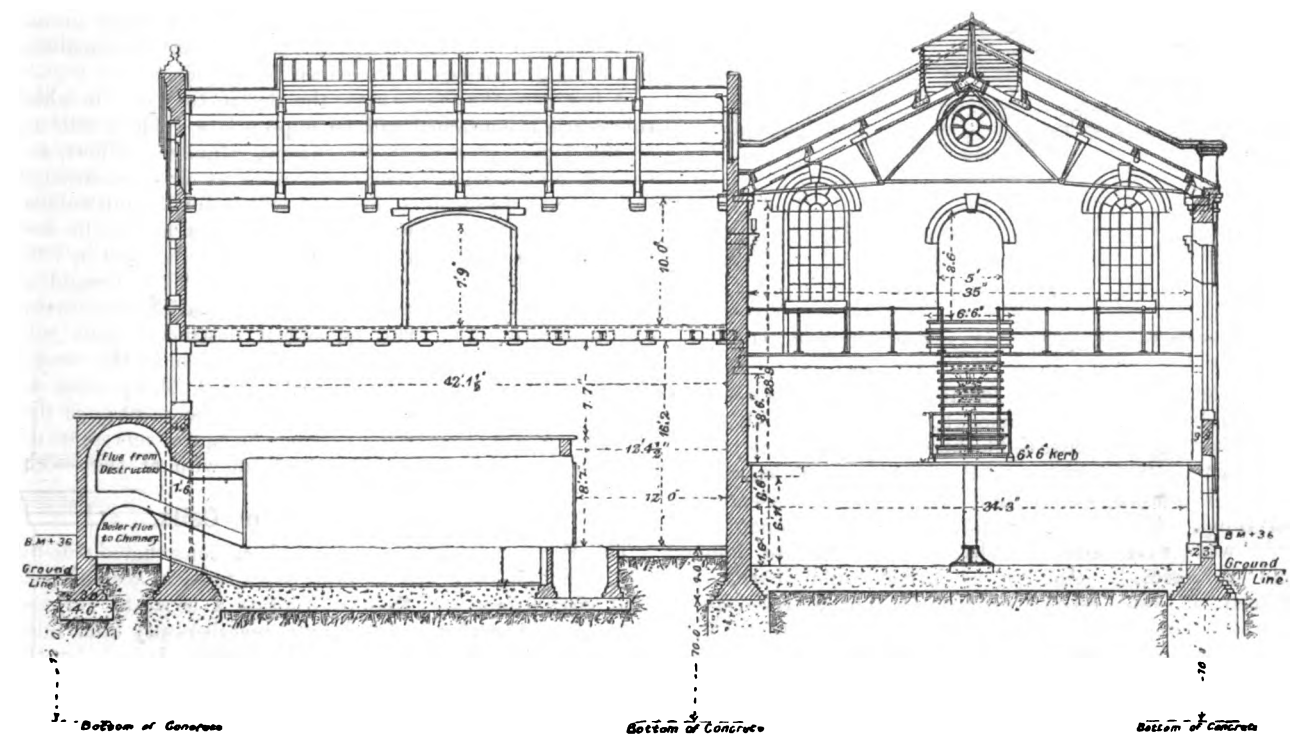
Transverse Section through Boiler House.

Longitudinal Section through Engine House.

has to be determined for the economical working of electricity works. Water obtained for this purpose from the Grand Junction Waterworks Company's mains would have been so expensive as to have rendered its use prohibitory. Consequently, Messrs. Bramwell and Harris suggested the use of the sewage effluent for steam condensing. So long ago as the year 1887, Messrs. Bramwell and Harris designed for the Metropolitan Board of Works specially arranged surface condensers to be connected to the sewage pumping engines at the Board's Crossness sewage station, the circulating water of these condensers being the effluent of the London sewage flowing from the tanks to the river. The condensers were constructed and erected to these designs by Messrs. James Watt and Co. in the above year, and have been working satisfactorily ever since. The quantity of effluent passing away from the Ealing sewerage works amounts to 600,000 gallons every 24 hours, the excellent condition of the effluent allowing of its being satisfactorily employed in this direction before leaving the station.

Novel Departure from Existing Practice.

Thus it will be seen that in these electricity works a most striking and novel departure has been made—a deviation, in fact, from existing practice in central-station work that will be watched with the keenest interest by both electrical and municipal engineers throughout the country. Of course, in recommending the Board to adopt this system, the consulting engineers did not suggest that electrical energy could be produced for practically nothing, as some unreasonable persons would try to make out. What they did contend—and we consider rightly so—was that the advantages which would accrue from the combined utilisation of the waste heat from the destructors and the sewage effluent for steam condensing purposes, would allow of considerable economy being realised. To put the matter in a nutshell, it was a question of either paying heavily for water for condensing purposes and all the coal required, or using the heat going to waste, together with some coal, at little expense, and the effluent passing through the station at no cost whatever. In deciding to make the departure indicated by



Longitudinal Section of Boiler House.

Transverse Section through Engine House.

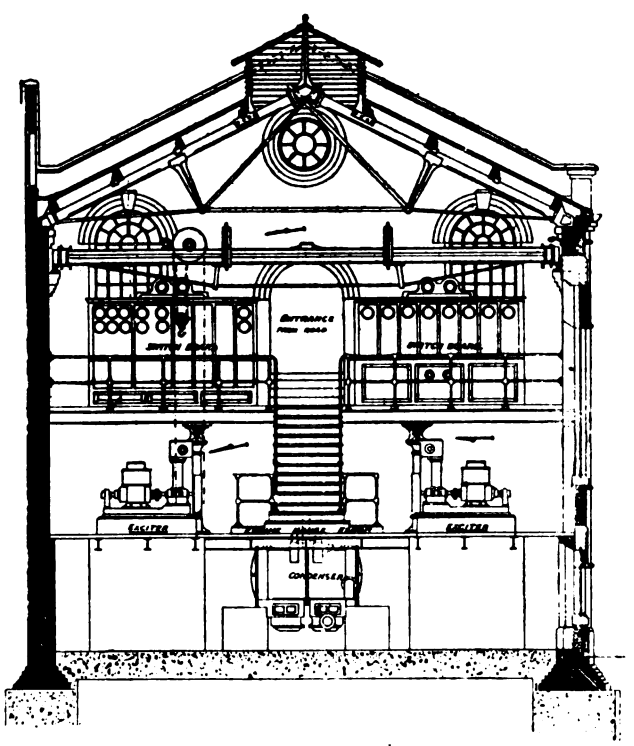
Digitized by Google

adopting the latter arrangement, the Board acted wisely. Not only so, but the actual working of the station will, as time passes away, determine from the practical experience gained—and this is what electrical engineers desire to ascertain reliable data upon—what economy is obtainable by the introduction of this combined system.

The Adopted System.

As already remarked, the site of the station and the large extent of the compulsory area of supply left no choice in determining the system of production of electrical energy. A low-pressure system, even with the use of sub-stations, was out of the question—at least, if the electricity works were to be operated with economy. Consequently, the only other resource was to put down a high-pressure alternating-current system in conjunction with transformer stations in different parts of the district for private supply, and high-pressure direct-current dynamos for public arc lighting.

Another interesting fact in connection with the scheme was that of public lighting. Hitherto, or at all events in recent years, the Local Board have paid to the Brentford Gas Company no less than £500 per annum for the illumination of those streets comprised within the compulsory area where mains had to be laid, whilst a further sum of



Transverse Section through Engine House, showing Generators and Switchboard in position.

£250 was expended annually for the lighting of the various public buildings. Naturally enough, by dispensing with gas and substituting the electric light, this sum would become available as part of the revenue of the electricity works, which from the beginning would thus become a money-earning undertaking. This fact was also impressed upon the Board, who were advised that 70 public arc lamps should be erected. As far as private illumination is concerned, it was estimated that within a reasonable period the probable demand would be equal to 5,000 8-c.p. lamps. Accordingly, the consulting engineers recommended the Board to put down plant for the supply of this number of lamps at a cost of about £21,000. The estimated revenue from public lighting was £750, and from private illumination for the whole of the 5,000 lamps installed £2,250, or a total of £3,000 per annum. The scheme was somewhat enlarged and the amount increased to £25,000.

As a result of the recommendations of the consulting engineers, the Local Board, as already stated, decided to carry out the scheme and to obtain a loan of £25,000 for the purpose. This decision was soon put into practice. Tenders were invited for the erection of the buildings, and for the supply of the steam and electrical plant. The following was the result.

Buildings: Wilkinson Bros., Finsbury Park	£7,381
Lancashire boilers and accessories: J. Watt and Co., Birmingham	1,875
Steam dynamos, alternators, transformers, switchboards, and condensing plant: Siemens Bros. and Co., Limited, London	7,450
Mains, lamps, etc., Callender's Bitumen Company, London	6,000
Wiring public buildings: Paterson and Cooper, London	795

The Destruction of Refuse.

Justice to the novel features possessed by the Ealing electricity works can only be done by a detailed description, which will be more readily understood by the aid of the accompanying illustrations; and in order to accomplish this object satisfactorily, we must follow each step from the commencement—that is, beginning with the disposal of sewage sludge and ashbin refuse at the works off South Ealing and Occupation roads. In this connection the following quotation from Mr. Jones's work, entitled "Refuse Destructors," may not be out of place:

"For some two or three years previous to the year 1883 considerable difficulty had been experienced in disposing of the sewage sludge, the Ealing sewage being treated by precipitation upon the milk-of-lime process. Whilst the surrounding lands were purely farm lands no difficulty arose, but gradually these assumed the character of market gardens, when considerable objection was raised to the material. We were next obliged to mix it with ashes, and instead of receiving 1s. and 2s. a load for it we had to give it away. At last the question became one of paying for its removal, and as we got more and more into the difficulty appertaining to its disposal, so did the market gardeners raise their prices, and in the end it cost some two to three hundred pounds to be rid of one year's supply. In the year 1882 I was at Leeds, attending a meeting of the Association of Municipal and Sanitary Engineers, and, amongst other objects of interest, saw for the first time the working of a destructor, and fully realised the fact that I had met with a contrivance which would enable me to set market gardeners at defiance. I laid the matter before my Board, and at once obtained their consent to the erection of a destructor, and in 1883 we commenced our burning. In 1885, the difficulty that arose in connection with the fumes, etc., was overcome by the cremator, and from that time to the present we have burned quite nine-tenths of our sewage and house refuse, the remaining tenth being transferred to our own farm lands."

A few remarks concerning the destructor cells in which this refuse is consumed will be appropriate. These cells are of the Fryer type, made by Messrs. Manlove, Alliott, and Co., of Nottingham. Two cells were at first constructed, this being in 1883, in conjunction with a small multitubular boiler and engine. Two years later three more cells were erected, together with a Jones "fume cremator," and in 1890 a further addition of two cells was made. This brought up the number of cells to seven, and the foundation for a further cell was also laid. This seven-cell destructor deals with about 24 tons of refuse daily, in addition to the sewage sludge arising from a population of some 23,000 persons out of a total population of 27,000. It may be mentioned that the difference between these two sets of figures represents the population on the northern incline dealt with at the sewage farm.

The Fryer Destructor Cells.

The Fryer cells at Ealing have been constructed side-by-side, although they can be built back-to-back, according to local circumstances. Each cell forms a separate furnace, comprising a cavity enclosed by a reverberatory arch lined with firebricks. The cell is provided with a hearth for the reception of the refuse to be burned, from which it passes into the furnace proper. The passage of the material to the front is facilitated by arranging the firebars in an inclined position, which also renders easy the removal of the clinkers. The top of the destructor constitutes a platform, an opening over each cell being provided for the reception of the mixture of sewage sludge and ashbin refuse, which is shot through the opening from small trucks. It will, of course, be understood that the opening for the admission of refuse is divided from that for the exit of gases, the division being formed by a wall, whilst a bridge is provided to prevent the refuse heaped on at each charge from getting into the flue immediately below. Special openings are provided for the direct

Digitized by Google

introduction upon the burning mass of infectious mattresses, diseased meat, dead cats and dogs, etc. The furnaces, when once lighted, are kept at work by the refuse itself. In order to prevent inconvenience to the stokers through the fine dust being blown about, a concave pit is constructed under the furnace bars. This pit is partly filled with water, and the fine dust falling therein is removed when the fires are drawn. The clinkering is done at intervals of about two hours, and the quantities of clinker and fine ash vary in proportion to the kind of material burned. The average dust at Ealing is about 25 per cent., a good hard clinker, suitable for a variety of purposes, forming the residuum. This clinker is used in the manufacture of concrete, for tar paving, for building and path-making purposes, hard core for roads, artificial stone when ground up as sand, and for the construction of walls. Thus the clinker forms a valuable by-product. The whole of the concrete and mortar used in the erection of the buildings of the lighting station has been made from this clinker, either used whole or ground up into sand.

An automatic arrangement has been adopted for the purpose of maintaining as constant as possible the high temperature in the dust-chamber during the operations of feeding and clinkering. This is accomplished by means of a cast-iron hinged door which is placed over the opening leading into the dust-chamber, and is attached by a chain to the furnace door. The arrangement is such that when the furnace door is open the entrance to the dust-chamber has about four-fifths of its area closed, whilst when the furnace door is shut the flue door is open. As already stated, this method is entirely automatic, and the admission of cold air during the operations in question is reduced as much as possible, when the desired result of keeping up the high temperature which is essential for the proper working of the destructor is obtained.

The Fume Cremator.

The difficulty arising from the emission into the atmosphere of the gases and vapours from the destructor cells has previously been mentioned. It arose partly from the expulsion of the gases at too low a temperature, and partly from the vapours given off in the drying of the material in the first stage of burning. The idea occurred to Mr. Jones that by the employment of an additional and *independent* furnace—arranged between the destructor and the chimney shaft, and in which a very high temperature prevailed—the difficulty could be overcome by passing the gases through it, and thence into the atmosphere, practically innoxious. This idea was carried into practice by Mr. Jones in 1885, and since then no complaints have been made of offensive fumes from the chimney, which is 143ft. high. To this additional furnace Mr. Jones gave the name of the "fume cremator."

The fume cremator consists of a reverberatory arch with rings of firebricks placed in the direction of the gases. Ribs of firebricks projecting from the arch serve to deflect the gases and direct them on to *the top* of a red-hot mass of fire. This furnace is fired with coke breeze alone, or coke breeze and ashes screened from the refuse, and an intense heat, calculated at between 1,200deg. F. and 1,800deg. F., is maintained at little expense for fuel, a supply of air being provided below the fire-bars and a further supply to feed the vapours as they pass into the cremator. The passing over this bed of incandescent coke at this high temperature practically completes the partial distillation commenced in the destructor cells of the gases, vapours, and fine dust, and what then enters the atmosphere through the chimney shaft is odourless. Between the cremator and the shaft is arranged a multitubular boiler, in which steam is raised by the hot gases for the purpose of driving an engine and mortar mill in the sewage disposal works.

The method outlined in the foregoing remarks is that which has hitherto been followed at the sewage disposal works, which, now that the electric light station is completed, will doubtless be termed the combined sewage disposal and electric light works. But with the establishment of the latter this arrangement undergoes certain alterations. In the first place, the existing cremator and chimney shaft will fall into disuse; and in the second, the whole of the waste gases from the destructor cells will be passed through another cremator of the same type, and utilised for steam-raising purpose in the boilers laid down for operating the engines and dynamos in the adjoining electricity works.

Waste Gases for Steam-Raising Purposes.

We now come to the first novel and interesting application in connection with this central electric light station—namely, the utilisation of the waste gases and vapours from the refuse destructor for the purpose of raising steam in the boilers. As will be seen from the general plan, etc., of the works, the gases from the main flue of the destructor pass through a damper into a horizontal brick flue a distance of some 30ft., where they are led over the burning mass forming the furnace of the new cremator, which is constructed on practically the same lines as that already referred to as having been erected in 1885, and which has been at work continuously since that year. The complete distillation of the gases and vapour being practically accomplished by the fierce heat prevailing in this furnace, the odourless gases, now at a temperature ranging between 1,200deg. F. and 1,800deg. F., are dealt with in either of two ways: they are either allowed to escape from the cremator flue into the chimney shaft through the damper shown in the plan at the base of the shaft, in which case the connection between the cremator flue and the flue from the destructor built at the end of the boiler-house is shut off by a damper, or the damper at the bottom of the chimney shaft is closed and the gases pass into the flue from the destructor and thence round the boilers, in which event, as a matter of course, the path to the boilers is clear.

The former method may be regarded as only being necessary in case it becomes essential or desirable at any time for some reason or other to raise steam in the boilers in the usual way, as, for instance, when the destructor is shut down annually for about a fortnight for repairs. Of the three boilers, of which details are given further on, each and all are adapted for steam generation in the way indicated. It must not be inferred from this statement that it is intended to generate steam in all the boilers by means of hot gases, but rather that any boiler or any combination of the three can be made to produce steam in this manner as occasion may arise. As a matter of fact, when the additional destructor cell (the eighth) has been erected, it is expected that the total power obtainable continuously from the eight cells and cremator will amount to about 50 i.h.p., or, say, sufficient to satisfy the day load for some years to come. Thus the utilisation of the waste gases from the destructor is really an adjunct to the steam plant, which in itself is quite independent of the refuse destructor when such independence is necessary.

Coming now to the details of the arrangements for utilising the waste gases for the generation of steam, it will be observed from the cross-section of the flue from the destructor (or, rather from the cremator) and of the boiler flue to the chimney, that these pass back around the outside rear end of the boiler-house, and that the flue from the destructor surmounts the boiler flue to the chimney. The admission of the hot gases from the flue from the destructor to the boiler flues and the exit of the smoke and gases from the main boiler flue to the chimney are controlled by a double damper, which is arranged on the inner side of the rear end of the boiler-house wall, as shown. When this damper is raised, the gases pass round the boiler flues and underneath into the main boiler flue to the chimney. At the same time the hinged ashpit dampers fitted to the cast-iron fire-door frames in front of the boilers, in addition to ordinary closed fire-doors, are closed so that the fronts of the flues are sealed up airtight, whilst the waste heat alone is being utilised.

When the double damper is lowered, the connection between the boiler and the flue from the destructor is closed, and the boiler is ready for steaming in the usual way. The raising and lowering of the double damper is effected by means of leading pulleys, chains, and counterweights. The counterweights are arranged in front of the boilers, so that the double damper may be operated from the stokehole.

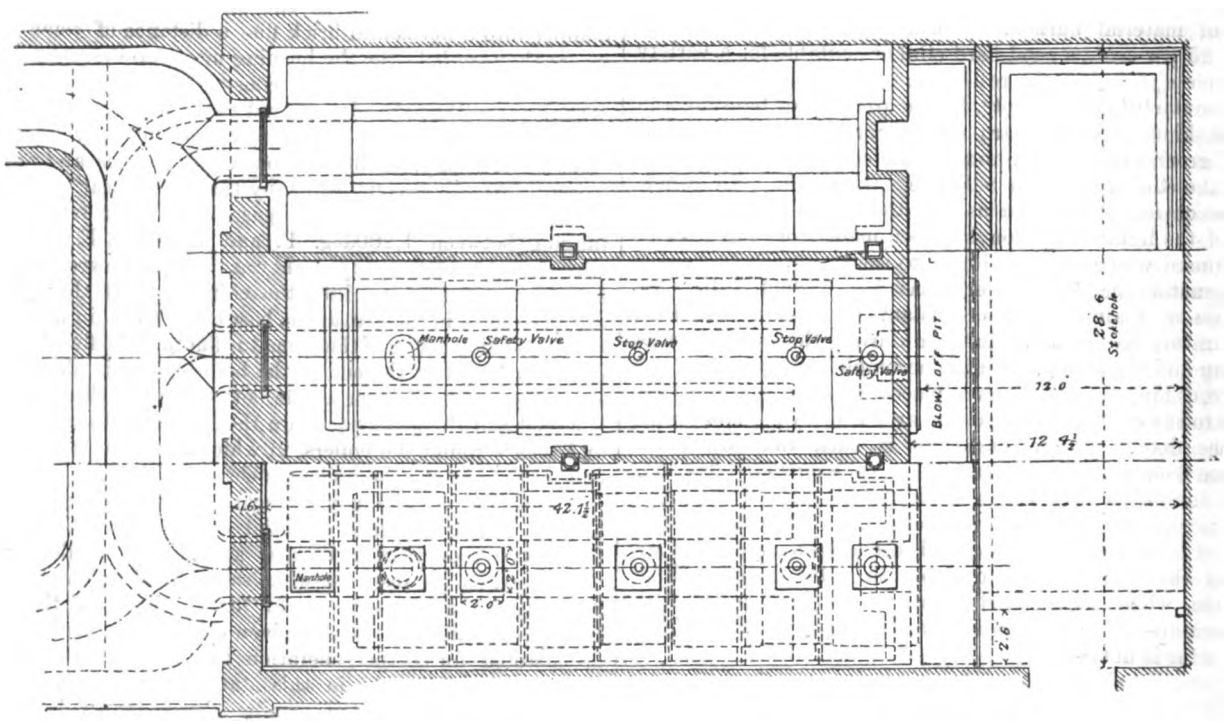
Further, as will be seen, the arrangement is such that hand or mechanical stoking of either or all of the boilers can be carried on simultaneously with the utilisation of the waste heat from the destructors.

The Boiler-House.

Subjoined are given illustrations of the station buildings. The contract for the boilers and accessories was placed

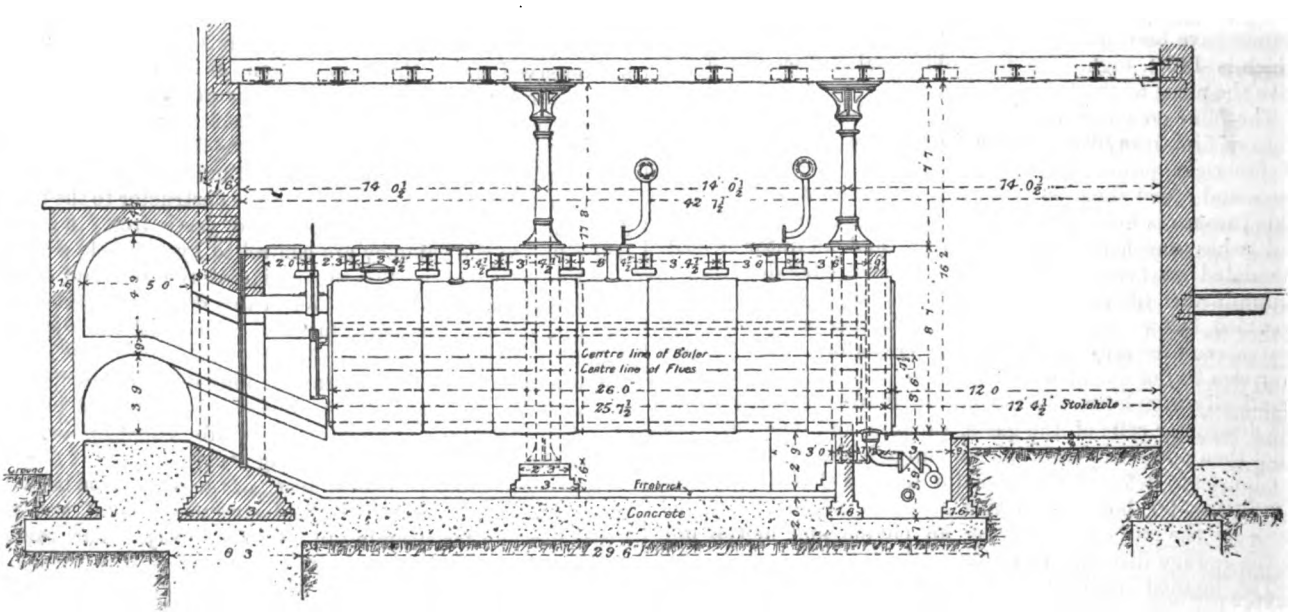
Digitized by Google

with Messrs. J. Watt and Co., of Soho Foundry, Birmingham. The boilers comprise three of the Lancashire type, constructed for a working pressure of 120lb. They are each 26ft. long by 7ft. in diameter, and are made of mild steel. Each boiler is provided with two flues, in each of which is arranged eight cross Galloway tubes of 10½in. internal diameter at the large ends and 5½in. at the small ends. Two of these tubes



Plan of Boiler House.

are placed in each of the parallel flue ring plates behind the furnaces. There are two manhole openings to each boiler: one is arranged in front of the boiler between the flues and below them, and the other is placed in the centre of the back row of shell plates at the top. The boilers are each provided with a double-lever safety valve and two screw-down stop-valves. The latter are bolted to fittings riveted to the top of the boiler, and each valve has a single right-angled branch,



Longitudinal Section of Boiler House.

which has bolted to it a copper bend to allow for expansion; this is turned upwards, and has its other flange bolted to the underside of two 6in. cast-iron mains, which are carried across the boilers at right angles to their length. These mains terminate at one end in a blank flange within 2ft. 6in. of the end wall of the boiler-house; they are at the other end taken through the wall into the engine-house, and finish in a flange to which the main steam-pipes to the engines are connected. Other flanges are provided for connecting the steam-pipes for the donkey feed pump, for the injector, and for the mechanical stokers. A Cowburn dead-weight safety valve is placed on the top of the boiler, and this, together with the double-lever safety-valve already referred to, is arranged to blow off when the boiler pressure reaches 130lb. In addition to these, each boiler is equipped with feed and scum valves, and with a Bourdon pressure gauge registering up to 160lb., and a set of Dewrance's water-gauge fittings.

The boilers, of which detailed illustrations are given herewith, are provided with a feed donkey pump of the Worthington horizontal duplex type; it is operated by steam from the boilers, to which it is capable of delivering 2,000 gallons of water per hour. A cast-iron flanged suction pipe is taken from the suction branch, and is connected to the water-tank in the tower, which is supplied with fresh water from the mains of the Grand Junction Waterworks Company. This tank was made by Messrs. Hunter and English, of Bow-road. The delivery from this pump is effected through a cast-iron flanged pipe connected direct to the feed main, arranged along the front of the boilers. The exhaust is either through the general condenser or into the atmosphere. An 8mm. Giffard injector is also provided, the steam supply

Digitized by Google

being obtained from the 6in. cast-iron main already mentioned. The mechanical stokers, which are of the McDougall type, are driven by an arrangement of cams and cone pulleys from a countershaft actuated by two small engines, which are also of the McDougall type.

Above the boiler-house is a coal-store capable of holding 100 tons of fuel, shoots being left in the floor so as to feed the hoppers of the mechanical stokers direct. The store is on a level with Occupation-road, and is equipped with a five-ton weighbridge, made by Messrs. Avery and Co., Limited, of Birmingham.

The Engine and Dynamo House.

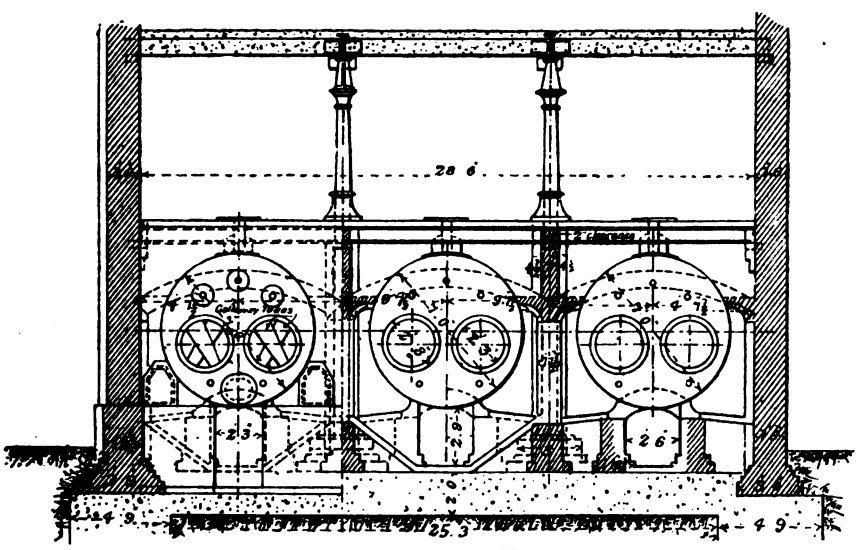
The main steam-pipes in the engine and dynamo room, which receive their supply from the before-mentioned couple of 6in. cast-iron mains, form a complete ring main, having copper expansion joints at the ends; whilst the exhaust pipes are arranged so that the engines can be run at high pressure, exhausting direct into the atmosphere when the general condenser is not in use. These steam-pipes, which are of cast iron, with flanged joints, are below the level of the engine-house floor, and the connecting pipes to and from the engines where they pass above this level are of copper, suitable bends being provided to allow for contraction and expansion.

The whole of the generating plant, comprising engines and dynamos, switchboards, condensing plant, and steam and other mains and pipes in the engine and dynamo room, has been provided under the contract entered into by Messrs. Siemens Bros. and Co., Limited, of Westminster. It is divided into two parts: one for public illumination, and the other for private supply. The plant for public lighting comprises three direct-coupled sets of Browett-Lindley engines, and Siemens constant-current dynamos; and for private illumination, four direct-coupled sets of similar types of engines and Siemens alternators, together with two sets of single engines by the same makers and Siemens exciters direct coupled. The engines and dynamos are laid on beds or piers of concrete surmounted by 18in. of stone.

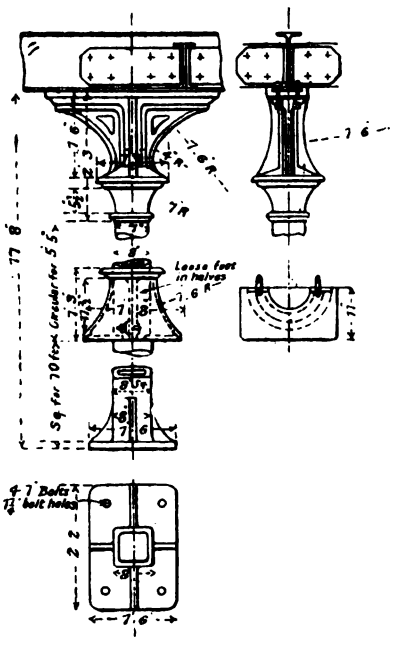
The three engines for public lighting are of the vertical compound condensing type, having cylinders 6in. and 10in., and a stroke of 8in. The crankshaft of each engine has cranks at right angles to each other; at one end it carries a heavy turned flywheel, and at the other it is coupled direct to the spindle of the dynamo by means of a flanged coupling. The engines are of 35 b.h.p., and run at 300 revolutions per minute. The generators to which these engines are direct coupled are Siemens H H D 32/13 dynamos, each giving 10 amperes at 1,800 volts for working a circuit of 40 arc lamps in series. This type of machine has a ring armature revolving in a double magnetic field circuit, and is provided with a regulator which automatically varies the voltage in proportion to variations in the external resistance, and thus maintains the current constant.

The four engines for private illumination are also vertical compound condensing, by Messrs. Browett and Lindley, and are direct coupled to their respective alternators. Two of the sets of engines are of 100 i.h.p., running at 200 revolutions a minute, and having cylinders 10½in. and 17in., and a stroke of 12in. These engines drive two Siemens W 24 alternators having revolving disc armatures and fixed magnets, and capable of giving 60 kilowatts at 2,000 volts at a frequency of 40 periods per second. The other two sets of engines are also of the Browett-Lindley compound type, each giving 50 i.h.p. at 240 revolutions per minute. The engines have cylinders 7½in. and 12in., and the length of stroke is 9in. These engines actuate two Siemens W 20 alternators having each an output of 30 kilowatts at the same pressure and frequency as the larger machines. These alternators are arranged for parallel running by connection with omnibus bars on the switchboard.

There are two exciting dynamos, these being of the Siemens H B 12/16 type, each giving 145 amperes at 66 volts. The output of these two machines is more than sufficient to excite the whole of the alternators simultaneously, they having, in fact, 33 per cent. excess of current over that required for the alternators. They are driven direct at 300 revolutions by two Browett-Lindley single-acting engines, each of 17 b.h.p., having a 8in. cylinder and a stroke of 8in



Cross Section of Boiler House.



Details of Pillars in Boiler House.

The Condensing Plant.

In describing this plant we come to the second novel feature in connection with this undertaking—viz., the use of the sewage effluent for condensing purposes. The condensing plant, which has been manufactured by Messrs. G. E. Belliss and Co., Limited, of Birmingham, is installed in the basement of the engine-house. The arrangement is compact, the air and circulating pumps, which are double acting, being supported on the condenser, and driven direct by a prolongation of the piston rods of the engines. The plant comprises a general surface condenser, to which is connected the main exhaust-pipe receiving the whole of the exhaust steam from the engines. This condenser and its pumps deal with the exhaust steam, not only from all the engines, but also with that from its own steam-pumps, which are vertical and direct acting. The cooling water for this condenser, which, as already mentioned, consists of the sewage effluent from the sewage settling tanks, circulates through the tubes, the steam playing outside them. The condenser has a cast-iron case or cover, and is fitted with solid-drawn tinned Muntz metal tubes ⅝in. diameter of bore 17 B.W.G. thick, secured in planed gun-metal plates. The area of the cooling surface afforded by the tubes, measured on their external face, is 1,500 superficial feet.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
ther Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIII. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

EALING.

It may be some of our readers will imagine that too much is made of this comparatively small installation, but it is well to have a complete description of what is to some extent a new departure. Refuse destruction is a phrase to conjure with among municipal engineers. They have, in the first place, to consider sanitary conditions, and from this point of view have to dispose of a large amount of refuse. How to do this safely and economically is the great problem of their lives. Advancing civilisation makes matters worse, in that a larger and larger population is congregating upon a given area. The tendency of modern municipal engineering is to utilise fire for the destruction of this refuse. Now, one of the properties that must belong to a furnace used for refuse destruction is that high temperature reigns supreme and the residual gases leave the furnace at a high temperature, hence there must be a certain amount of heat available for industrial purposes. So far as we know, Mr. W. B. G. Bennett, the engineer to the Southampton Corporation, was the first to make use of this heat to raise steam for the running of dynamos and the providing of electric light. Since his experiment many minds have been directed to the question, and in various places dynamos are run in connection with refuse destructors. Ealing, however, is the first authority to systematically tackle the question in its public lighting arrangements. Its engineer, Mr. C. Jones, is recognised as an expert upon all that pertains to refuse destructors, and no doubt his views mainly directed his authority in coming to the conclusion they have done. Mr. Jones is nothing if not progressive, and from an engineering point of view it would be difficult to find a suburban district more carefully looked after. The consulting engineers, Messrs. Bramwell and Harris, as will be seen from the description of the station, have accepted the idea of using the waste heat from the destructors as an aid to direct heating, and the experiment will be anxiously watched by the many engineers who have or will have the control of destructors. What the money value of that aid will be is a matter time alone will determine, but no doubt there will be an appreciable saving in coal, and again in using the sewage effluent for condensing purposes. It seems to us, then, that the Ealing station has some novel features worthy of close attention from the very first day of work. We have often heard Mr. Jones express his belief in works, not words, and as crediting actual results rather than theoretical conclusions. Time must show if the anticipations at Ealing are to be realised in practice.

INDIRECT ECONOMIES.

The statement of Mr. Whiteley as to the saving of £500 a year in less paint and whitewash by using the electric light must be taken for what it is worth. At any rate, even if the saving hardly reaches this figure, there is little doubt but that in large establishments of the kind the indirect saving must be

Digitized by Google

considerable. Seldom do those who advocate the retention of gas admit of any except a direct comparison with gas as to cost. This is not fair as regards electrical work, for in many cases the indirect saving must be of paramount importance, and this must be considered in ascertaining the actual cost. Gradually this view of the case is being better understood, and as the result more householders are asking about the light. Thus while there may be no fear, even when the result is cost for cost, the inducement should ever be held out that the indirect benefit ought to ensure the installation of the newer illuminant.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE ETIQUETTE OF JOURNALISTIC ELECTRICAL ENGINEERING.

SIR,—Probably no one takes the leaders and notes in the *Electrical Review* seriously; unless one has plenty of time on one's hands, one usually skips both. They are generally written in a somewhat grandmotherly style, occasionally tempered by the acidity often attendant on the stage known as coppy and surly. Still, it is somewhat startling to find the *Review* claiming immunity from criticism for an inventor who is introducing a new apparatus, on the ground of the unwritten law of etiquette that rules with engineers. One feels tempted to asked whether the editors of the *Review* consider themselves engineers, or on what ground they claim to be freed from this etiquette? No technical journal more frequently disregards even the ordinary courtesies that should rule between the strongest opponents, or claims greater license for itself.

Is one at liberty to criticise an apparatus that an enthusiastic inventor wishes one to purchase? If one is a partner in a firm that is asked to take up some new apparatus, does this mysterious etiquette bar one from giving one's reasons for one's judgment, or should the enthusiast be allowed to exhaust his arts upon a silent audience? If one is a shareholder in an industrial concern in which there are few having any knowledge of some particular apparatus that the concern is desired to adopt, is one not to give one's fellow shareholders the benefit of one's knowledge; or should one keep silence and meekly pay one's share in case of failure? And what is a ratepayer of any particular town but a shareholder in the town and in the undertakings that may be entered into by the governing body of the town? And when, as too often happens, no one on the town council possesses the smallest knowledge of a new undertaking that is being carried out, is not any ratepayer possessing knowledge of the subject really performing a duty to his fellow townsmen in criticising the work, both in its inception and progress? Of course it is annoying to an inventor who can see no difficulties in his path that he cannot easily overcome, as he thinks, and who is accustomed to treat large sums of money as of no consequence so long as a certain object may possibly be accomplished, to have possible sources of failure pointed out. Supposing that by timely criticism a large sum of money may be saved to the ratepayers, is some abstruse theory of etiquette to cause the expert to withhold the information at his command?

But perhaps the strangest point of all in this odd claim set up by the *Review* is that in another part of the paper the same writer claims for himself—and freely exercises it, too—the right to criticise everything and everybody, and severely lectures members of the medical profession, in the good old motherly style peculiar to him, for not supporting him in a crusade he has undertaken in a matter in which he has no concern beyond the general interest taken by all who are electrical engineers in everything connected with electricity.

Some weeks since the *Review* devoted two and a half columns to criticising some remarks of the present writer's in a local paper. Where did this mysterious etiquette come in then? The present writer was solemnly warned against the danger of a little knowledge, and the bad end he would undoubtedly come to if he persisted in using his little knowledge; yet, apparently, the etiquette—was it of journalism or this unwritten one of engineers?—did not allow the editors to reply when their arguments were shown to really prove the points the present writer had brought forward.

Would it not be as well for the editors of the *Review* to study courtesy in their own columns and in the work of their own pens, and leave such mysterious etiquette to take care of itself? Do they not see that while they themselves are claiming the fullest freedom in their criticisms, they are doing their little best to stifle criticism in others?

Yours, etc.,
SYDNEY F. WALKER.

A DEFINITION OF E.M.F.

SIR,—It is indeed astonishing that no author seems to define in a really unobjectionable manner a so fundamental conception as that of E.M.F. The general use of defining it as a difference of potentials is a more or less misleading one, for an E.M.F. may exist even without a difference of potentials, and sometimes it cannot be reduced to that form by opening the circuit. Moreover, such a definition is circuitous—it explains an unknown thing in terms of an equally unknown and not very different one.

Very abstruse and unpractical is the definition of E.M.F. as the line-integral of the electric force, and it leads to uncertainty in some cases; it is inelegant, as being founded on a preliminary electrostatic knowledge, which is rather extraneous to the understanding of electrodynamical phenomena. Profs. Anthony and S. P. Thompson define E.M.F. on purely dynamical base, but in too vague terms, for they do not give any means of reckoning the quantity defined.

I think a proper definition of E.M.F. may be expressed in the following terms, with no other previous knowledge supposed, except that of electric current (quantity of electricity naturally follows, being the product of the current into time.)

Every current flowing in a circuit has always to overcome some oppositions, because in its flow it always generates some kind of work; therefore, it cannot be maintained unless some exterior factors, acting on the circuit, assist the flow by supplying to the current the energy it is spending elsewhere. Everyone of these agents is called a source of E.M.F. It is incorrect to speak of them as sources of electricity, because electricity, like matter, cannot be generated or destroyed, but only set up into circulation.

A source of E.M.F. applied to a circuit is therefore everything that forces or tends to force electricity into a certain motion along the same, and in so doing it necessarily impresses a power when this motion really takes place. The strength of the source, or its capability of determining the flow of electricity, is properly reckoned* by the work it is doing when a unit quantity of electricity is displaced along the circuit, or by the ratio of its activity, K (*i.e.*, power, or rate of doing work), to the intensity, C, of the current flowing at the same time. To this value $E = \frac{K}{C}$, we give the name of E.M.F.

Similarly, every opposition raised against the current is called a source of counter E.M.F., or of negative E.M.F.; for it has a negative activity, and absorbs power from the circuit. It is to be understood that a source of E.M.F. is not necessarily an external one, for the work given out may be supplied from the energy stored in the current itself. Therefore, the impulse given to the current by a diminution of the stored energy is to be accounted for as an intrinsic E.M.F., and the opposition raised by its increase, as an intrinsic counter E.M.F.

The above definition holds true in every case, and it presents no difficulty to be understood. It enables us to write down easily the equations of current in every circuit, as a consequence of the conservation of energy.

* I think no difficulty will be found in this assertion; if so, it could easily be proved.

Digitized by Google

Thus, knowing the work done by a current, c, in a voltameter during a time dt is $p\,q\,c\,dt$ (where p is the electrochemical equivalent, q the specific energy of formation of the electrolyte), we see immediately that the counter E.M.F. of the voltameter necessarily equals $e = \frac{p\,q\,c\,dt}{c\,dt} = p\,q$, according to a well-known law.

The term E.M.F. is not, as claimed, an unfortunate one; on the contrary, it is properly chosen in perfect harmony with the most scientific terminology of modern dynamics. Indeed, according to the generalised theory of Lagrange, in every system whose actual condition depends upon the values of n variable quantities, we mean by "component *force* applied by an exterior agent to the element x" the energy communicated by this agent to the system per unit increase of x, when the other variables remain unchanged.

In a linear circuit the only variable is the quantity, q, of electricity displaced along it, and the energy impressed by an exterior agent per unit increase of q is what we have termed E.M.F. Of course, not all forces are of the same kind. An electromotive force and a Newtonian (or ponderomotive) force are of a quite different nature, for the one acts on electricity, and the other on matter; but the *work* done by the one in displacing electricity, and by the other in displacing matter, are absolutely of the same kind, and may be expressed in terms of the same units. It is the capability of generating a work, measurable in ergs, which enables us to assign to something the character of a force.

Yours, etc.,
G. GIORGI.

Rome, September 17, 1894.

THE ELECTRICITY WORKS AT EALING.

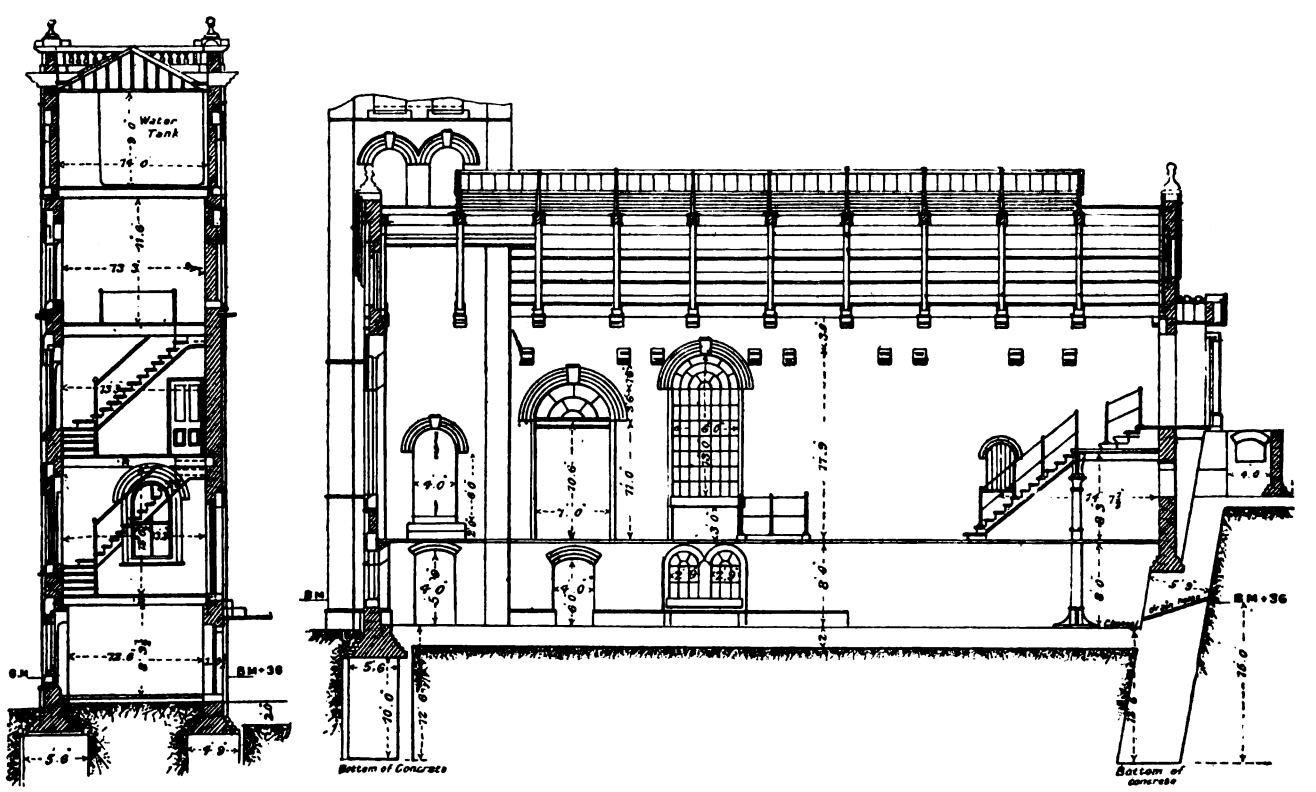
(Continued from page 359.)

The circulating pump suction and delivery pipes are connected to the sumps in the effluent outfall passing through the works. The air-pump suction is connected to the condenser, and its delivery is connected to one of the side plates of a cast-iron close-topped tank or hot-well 4ft. square internally, placed on the floor of the coal-store above the boiler-house. This tank is constructed of six cast-iron ribbed plates, with planed flanges bolted together, and is provided with a planed facing cast on one of these plates to take the flanges of the suction pipe to the boiler feed pump; and with a planed facing on the top plate to take a 4in. wrought-iron open top standpipe, which is sufficiently long to pass through the roof of the boiler-house, delivering there into the roof gutter, and with a facing to take a 3in. cast-iron overflow pipe. Arrangements are provided for emptying this tank when desired.

The placing of the generating plant in position has been facilitated by the employment of an overhead traveller, made by Messrs. Marshall, Fleming, and Jack, of Motherwell. This traveller, which has a span of 35ft., runs on wheels carried on rails secured to stone corbels built on the side walls. It consists of two 12in. by 6in. by 6in. rolled steel joists, trussed underneath, these joists having upon them a four-wheeled travelling carriage supporting an eye for the hook of a self-supporting half-chain pulley block. The traveller is also equipped with traversing gear, so that it may easily be moved the whole length of the engine-house. A plan, elevation, and cross-section of the traveller are annexed. The makers have supplied travellers for other central stations in the kingdom.

The Switchboard Arrangements.

The main switchboard, which is arranged on a stone platform at one end of the engine-house as shown, is divided into two parts. The part on the left-hand side controls the machines and arc light circuits, and that on the right carries the switches, ammeters, and fuses for the seven high-tension feeders. In a future issue we hope to illustrate and describe the board in detail. For the present it may be mentioned that a separate enamelled slate panel is provided for each alternator and feeder. Each of the four panels to the extreme left controls one alternator, and is fitted with a voltmeter, ammeter, two fuses, a double-pole main switch, a switch for breaking the field through a non-inductive resistance, and a field regulating switch. The four field regulating switches are geared together, so that the voltage of all the machines can be raised at the same time, or, when required, each machine can be varied separately by disconnecting the gear. On the panel, to the right of these four alternator panels, is mounted the apparatus for controlling the two exciters; each exciter is furnished with an ammeter, voltmeter, pilot lamp, double-pole main switch, which is interlocked with a field switch, a field regulating switch, automatic cut-out, and two fuses. This panel also contains a double-pole switch and two fuses for the station lighting current, which is supplied by the exciters, and synchronising apparatus, with switches to put the synchroniser on the omnibus bars and on to any machine. The next panel controls the constant-current arc



Longitudinal Section through Engine House.

Digitized by Google

lighters and circuits. It carries for each of the three machines an ammeter, voltmeter, a switch for short-circuiting the field, and a switch for connecting the machines to either of the arc light circuits. Two multiple-way switches are arranged below the feeder panels for connecting the two pilot voltmeters at the top to the various feeders on the other part of the switch-board. The cables for the electrical connections are carried on the rolled joists supporting the engine-house floor, the mains being placed under this floor except where they turn upwards to connect with the dynamos or switchboards.

Digitized by Google

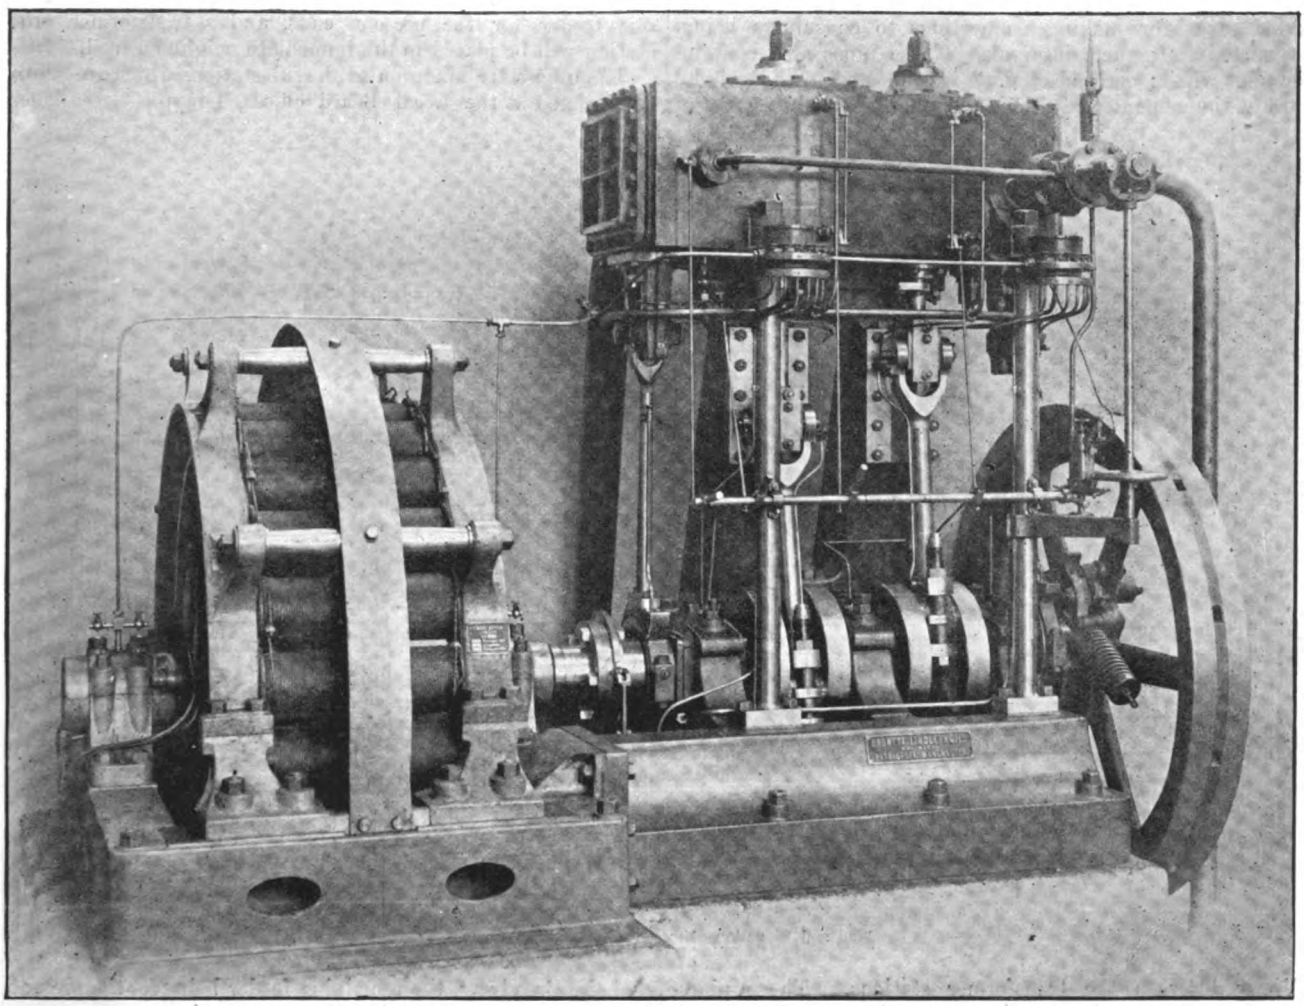
The arc lamps in the sewage and electricity stations are fed from the direct current of the exciters, whilst the incandescent lamps are on the alternating-current circuit, thus minimising the probability of all lights being out in the station in case of breakdown of any machine. For the purpose of supplying these incandescent lights a pair of leads is taken from the board to the engine-house basement, and there connected to the primary circuit of a transformer contained in a cast-iron case supported on brackets secured to the engine foundations. This converter, which is fitted with the necessary earthing devices, transforms from 2,000 volts to 100 volts the current for 80 16-c.p. lamps for the illumination of the sewage works, electric light station, and premises generally. The leads from the terminals of the secondary circuit of this transformer pass to a switchboard placed in the office of the resident engineer, where the lighting of the combined works is controlled by three switches.

underground, at a depth of 2ft. 6in., have a sectional area of copper of ·0225 square inch in each circuit. The arc lamps, which are of the Brockie-Pell type, made by Messrs. Johnson and Phillips, of London and Charlton, are capable of burning for 32 consecutive hours without the necessity of being retrimmed, and taking 10 amperes at from 45 to 50 volts. The arc lamps are suspended at a height of 24ft. from the ground by means of brackets arranged at the top of iron standards, rising 27ft. from the ground level, and cast by Messrs. A. Handyside and Co., of Derby and London.

The Feeder and Distributing Method for Private Lighting.

The "feeder" mains passing out of the generating station at the "main outlet" for the transmission of the high-pressure alternating current to the primary circuits of the transformers are also of the concentric lead-covered armoured



Direct-coupled Siemens Alternator and Browett-Lindley Engine.

The Distributing System for Public Lighting.

Another noticeable feature in connection with the Ealing electricity works is the number of public arc lamps placed in Uxbridge road, the Broadway, High-street, the Green, down to St. Mary's Church, and thence down the South Ealing-road to the generating station. The whole of the work in this direction, as also in the case of supplying and laying the feeders and distributing mains, junction-boxes, etc., for the supply to private consumers, has been undertaken by Callender's Bitumen, Telegraph, and Waterproof Company, of 101, Leadenhall-street, E.C., as previously mentioned. The lighting of these thoroughfares is accomplished by means of 70 10-ampere arc lamps arranged in series and energised from two circuits, the length of each of which is 7,000 yards. These lamps are arranged on alternate circuits, so that in case of accident to one circuit the lamps on the other are still available.

The arc light mains are concentric, lead covered and armoured, have an external waterproof covering, and are laid directly in the ground. These mains, which are laid

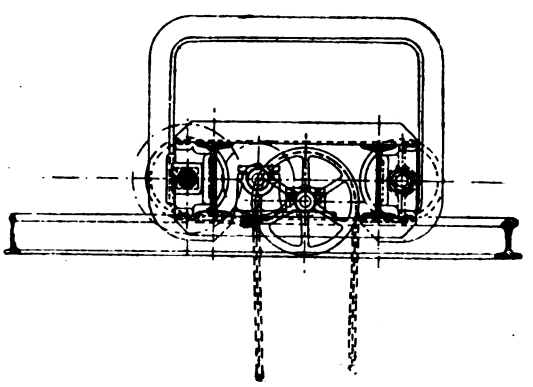
type, and similarly to those for the public supply, so also are these placed direct in the ground at a depth of 3ft. There are five feeder circuits, each of which has a sectional area of copper in each main of ·352 square inch, but provision has been made for two more. These mains have an insulation resistance of at least 1,500 megohms per mile at 60deg. F. and between conductor and conductor, and 750 megohms between the outer conductor and earth.

There will eventually be at least six transformer stations, as shown on the map of the compulsory area, but at present only five have been provided. At these stations the 2,000-volt current is transformed down to 102 volts. One of these is situated in the public buildings in Uxbridge-road, where are installed two Siemens converters, each of 21 kilowatts capacity, and capable of supplying some 600 lamps of 8 c.p. Three of the other transformer stations will be arranged in the base of three of the arc light standards. Each transformer-box is equipped with Cardew earthing devices with proper earth-plate. The connections for each transformer-box from the feeder mains to the primary circuit of the transformer, and

Digitized by Google

from the secondary circuit to the distributing mains, are brought through a separate underground box containing the necessary resistance and fuses, and by means of double-pole switches any one transformer may be put out of work, either through its primary circuit, secondary circuit, or both together. By this arrangement it will be evident that it is not necessary to open the transformer-box to cut out any converter, etc.

The distributing or service mains passing out of these transformer stations are insulated with vulcanised bitumen, taped, braided, and waterproofed, and are connected to the secondary circuits of the transformers and to each other so as to form a complete ring distributing main, in a manner similar to that which is in such successful use in the Derby installation. From these mains the connections to the customers' wires are made. These mains, which have a sectional area of copper of ·428 square inch, carry the low-pressure 102-volt current. They are laid underground in earthenware drain pipes at a depth of about 2ft. 6in., service boxes for making connections to consumers being constructed at frequent intervals. These pipes also contain four pilot wires; one end of these is connected to the switch-board at the generating station, and the other end to a point half-way between the transformer stations. These pipes range from 4in. to 6in. in diameter, and are socketed and jointed in Portland cement mortar. In a few cases, however—*i.e.*, where the pipes are laid beneath roadways—cast-iron socket pipes of the same diameters are used.

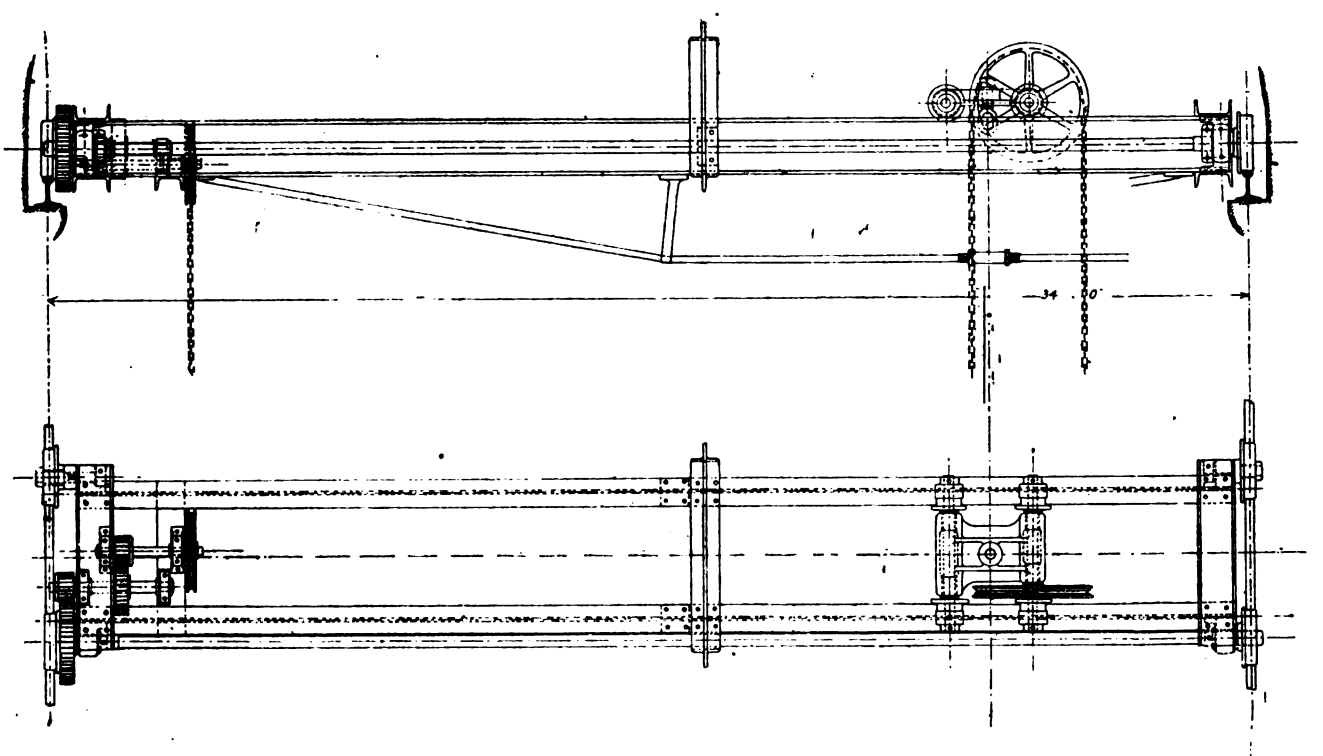


Section of Overhead Traveller.

So far as the mains are concerned, we may enter into a few more details. The entire contract outside the central station was placed in the hands of the Callender Company, and it includes not only the underground mains, but also the lamp-posts, arc lamps, and the various accessories required for the proper working of the apparatus.

The mains are of three classes—one to carry the high-pressure current to the various transformer sub-stations, known as feeders; a second for use on the arc lighting circuits; and a third to supply the consumers with a current of electricity at low pressure, this network being fed into at frequent intervals by the transformers. The feeders consist of lead-covered concentric cables with a dielectric of bitumenised fibre. The lead sheathing is served with a coating of yarn, then armoured by a double layer of steel ribbon, yarned over all, and finally waterproofed. Special precautions have been taken both in the manufacture and laying of these cables to ensure their long life and freedom from injury. They are five in number, and are laid in one trench from the generating station at the southern sewage works, along South Ealing-road and St. Mary's-road to the Greenview Corner. Here one feeder for the present ends, and a transformer sub-station will be placed in the immediate neighbourhood.

The others are taken on to the sub-stations which are being constructed at the Local Board offices, Drayton Green-lane,



Plan and Elevation of Overhead Travelling Crane.

and the Broadway, the remaining feeder being for the present left at the Feathers Hotel for future extension.

For the arc lighting, two concentric cables have been laid in the same trench as the feeders. These are exactly similar in manufacture to the feeders, and are laid along South Ealing-road, St. Mary's-road, and the High-street to the Broadway, and branching there east and west, will be carried without delay to the Acton and Hanwell boundaries. The feeder and arc cables are supplied in 500 yards lengths, and joined throughout in Callender's special cast-iron boxes for concentric work. About seven miles of feeder cables and six miles of arc cables are being laid.

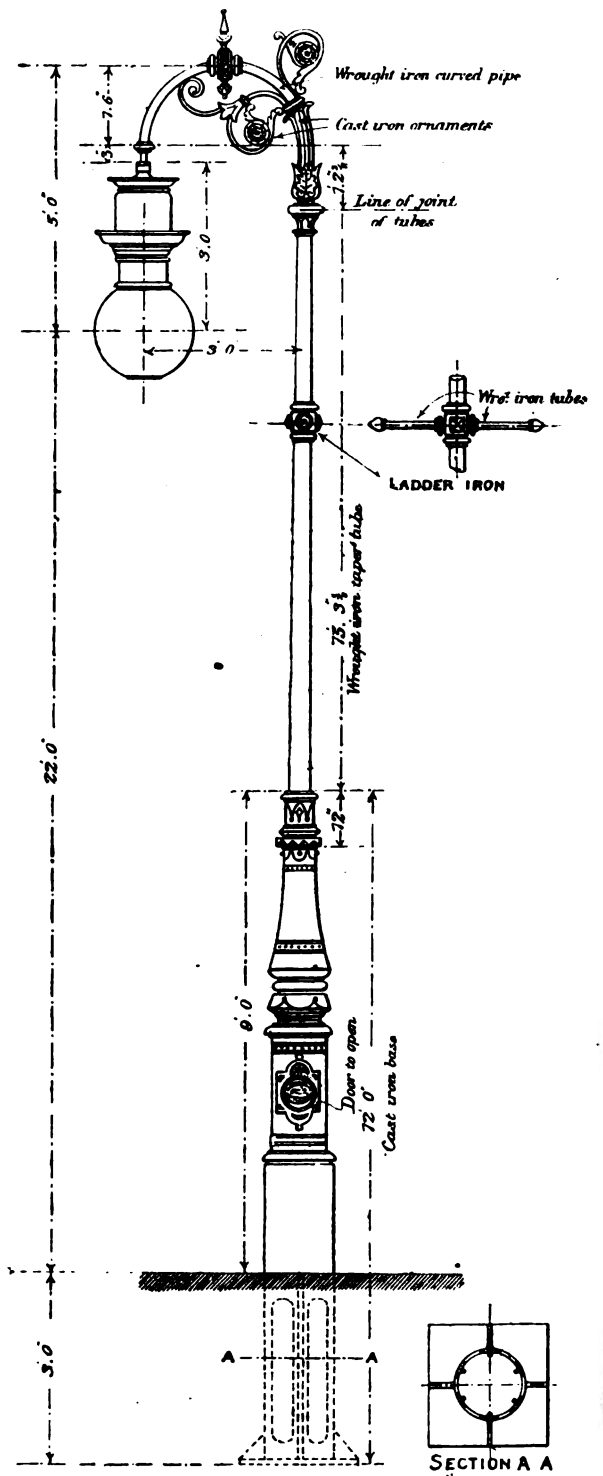
Of the 70 lamps to be put up, one-half is now in position. These are connected alternately to either main by means of branches taken out of boxes specially designed for this work. Brockie-Pell lamps and switches are being used, and a new form of carrier has been got out for the Ealing contract. The lamp columns, as already stated, have been cast for the Callender Company by Messrs. Handyside.

The distributors consist of pairs of cables, the type of which is so largely used for low-tension work all over the country. These are drawn for the most part into 4in. pipes, stoneware under footways, and

Digitized by Google

iron under the roadway. In the Uxbridge-road, however, where the mains are laid for nearly a mile under the roadway, 6in. cast-iron pipes are provided for the distributors. Brick pit boxes are constructed on the pipe line at suitable intervals, as is usual on a drawing-in system. The roadway manhole covers are Brown and Wood's patent, and the footway covers are of the Callender type.

The house connections are made by inserting a small brick pit on the pipe line and running a branch pipe from it into the consumer's premises. The service cables are connected to the distributing mains by joints thoroughly insulated.



Elevation of Arc Lamp Standard.

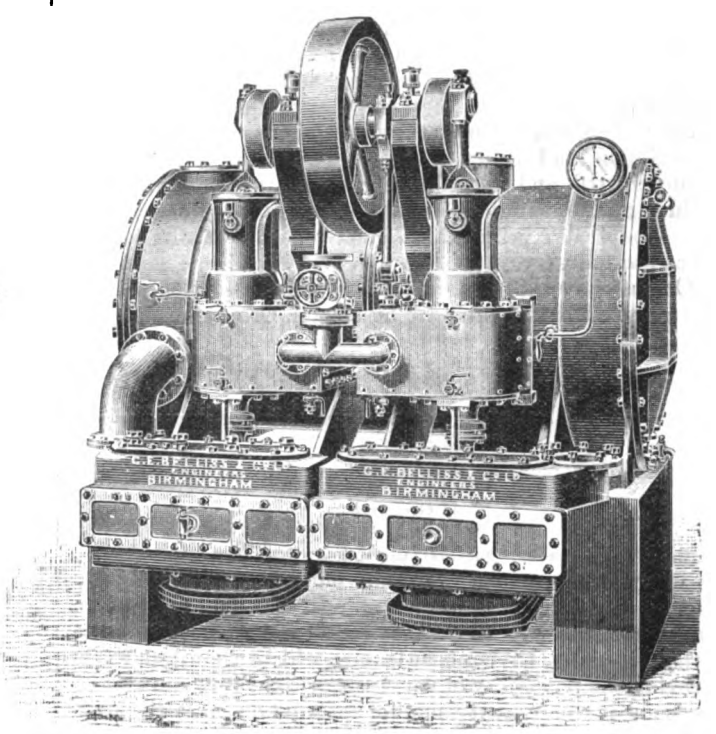
In addition to the electric light mains, a complete system of telephones with metallic circuits has been put down in the same trenches to connect the fire station with various points. These cables are lead covered and armoured, and are laid direct into the ground, branch boxes being provided to connect up the different buildings. This part of the work was commenced under the superintendence of Mr. H. Schiassi, and is being completed by Mr. F. E Procter for Messrs. Callender.

Lighting of the Public Buildings.

The work of wiring the various public buildings owned by the Local Board has been undertaken by Messrs. Paterson and Cooper, of Dalston, N. A portion of these buildings is centred in the structure in the Uxbridge-road, embodying the Public Offices, Victoria Hall, and the Public Library, whilst the remainder comprises the Baths, Fire Station and Stables, and the Fever Hospital, the latter being situated some 180 yards distant from the generating station. In each case the connections from the Board's supply mains to the interior of these buildings have been executed by the Board, who have also provided the main cut-outs and meters for measuring the current used. The contractors' work has been to wire the buildings in question, and to provide the main and branch switchboards, instruments, pendants, and fittings, and to adapt the existing gas fittings in certain cases.

Conclusion.

As already stated, the streets in the compulsory area are lighted by means of 70 arc lamps, and the number of applications sent in by private consumers for lamps is already equivalent to about one-third of the possible output. The charge for current to the public is 6d. per Board of Trade unit for lighting purposes and 4d. per unit for motive-power purposes, the current used being measured through Shallenberger meters. The local gas supply is furnished by the Brentford Gas Company at 3s. 3d. per thousand, and at this rate the inhabitants of Ealing should find it advantageous, both from the point of view of a superior illuminant and from that of a light which is more healthy, and not destructive to wall papers, ceilings, curtains, books, and other household effects, as is the case with gas lighting, to discard gas and substitute the electric light. The sooner the Ealingites take up the whole output of the station, which, as mentioned in the early portion of this description, has a capacity of 5,000 8-c.p. lamps, the better will it be for them directly and also indirectly by allowing the profits of the undertaking to be devoted either towards local improvements or to the relief of the rates. There is every prospect of this period being almost immediately reached, and of extensions of the generating plant being required.



Belliss's Horizontal Condenser.

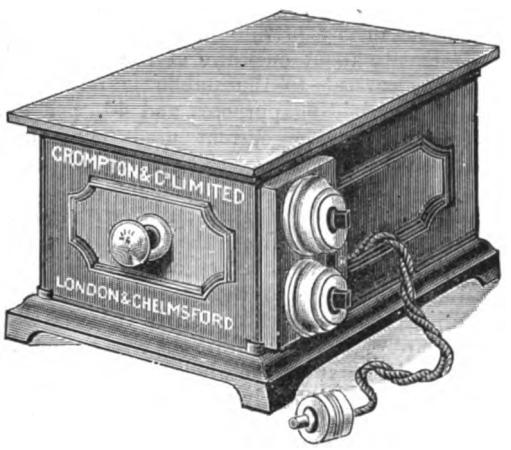
In concluding this article we must congratulate Messrs. Bramwell and Harris on the thoroughness with which the Ealing electricity works have been designed, equipped, and brought to the present position. Not only this, but the boldness and strikingly original characteristics of the works reflect great credit upon them, and also upon the Ealing Local Board, advised by their engineer, Mr. Jones, who had the courage to adopt and introduce a scheme possessing such

Digitized by Google

novel and interesting features as are embodied in the electric light station now set in operation. Our thanks are due to the consulting engineers for the plans and information placed at our disposal; to Mr. Ford Moore, their superintending engineer at the works, for his kind assistance; and also to the firms who were engaged in the different parts of the works now completed. The only remark necessary to terminate this article is to tender our best wishes for the success of the undertaking, and to hope that the extensions now foreshadowed may speedily become necessary.

ELECTRICAL EXHIBITION AT EALING.

An electrical exhibition in connection with the inauguration of the electricity works of the Ealing Local Board, of which a fully illustrated description is given in another part of the present issue, will be opened in the Victoria



Breakfast Cooker.

Hall, Uxbridge-road, on Wednesday next, and will be continued for 10 days. Apart from the exhibits made by various firms in the practical applications of electricity in the directions of lighting, heating, and working, and for motive power purposes, interesting attractions will be provided by demonstrations of the electrophone, the phonograph, search-light, and lectures. A large attendance of the public is anticipated, and the exhibition should not only result in inducing the inhabitants to take up a supply of electricity, but should also bring about good business results to the electrical industry.

One of the most novel features of the exhibition will be the electrical buffet, provided by Messrs. Crompton and Co.,

Electric Frypan.

Limited. The catering department here will be supplied with heat for cooking and warming purposes exclusively by electricity. This is the first instance that we aware of in which electricity has been used for such a purpose. Large urns, hot-plates, hot-cupboards, etc., will be shown at work, proving the possibility of using electric cooking apparatus, as made at the present time, for catering on a fairly large scale. The absence of smell from the usual gas arrangements and of danger of fire will be noticeable features.

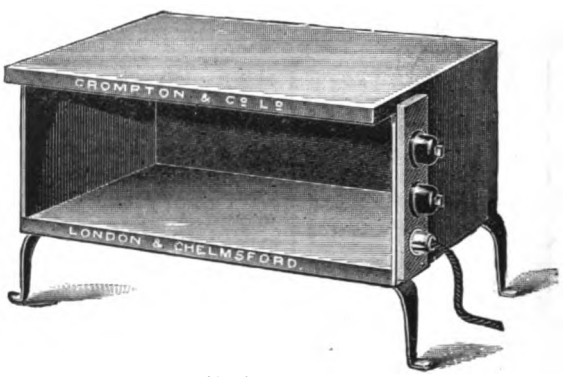
Messrs. Siemens Bros. and Co., Limited, of 12, Queen Anne's-gate, S.W., who have been prominently connected with the electrical plant for the Ealing central station, will show an assortment of samples of cables for laying underground, and samples of indiarubber wires for housework. In addition to these, a display will be made of a variety of switches, cut-outs, dry batteries, etc.

Mr. Harry South, of 10 and 12, Garrick-street, Covent Garden, W.C., will demonstrate a collection of high-class electroliers, brackets, standards, etc. These goods are made in London, and are highly finished with particular attention to detail.

Messrs. Crompton and Co., Limited, of Mansion House-buildings, E.C., and 148, Brompton-road, S.W., who will demonstrate the latest applications of electricity for domestic use, will make a prominent feature of their

Electric Hot Plate.

electric heating and cooking appliances, from electric kettles and saucepans to electric ovens, similar to those that will be used to cook the dinner on the opening night. Some of these appliances are illustrated herewith. The



Hot Plate Stand.

difficulty as regards finish in the earlier applications has been overcome, and the greater part of the apparatus is plated and highly polished. Various types of kettles will be on view fitted with electric heating arrangements at the

Electric Heater.

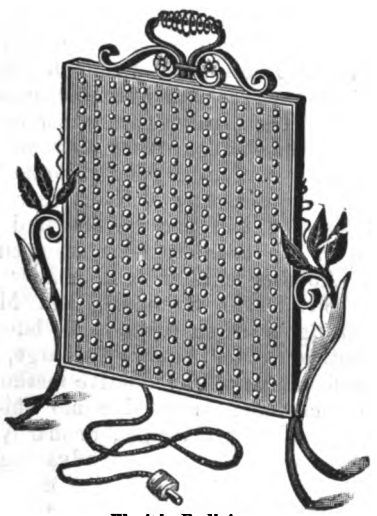
bottom, and no bare terminals are shown. The electric frypans consist of steel pans copper cased, and the connecting wires are brought to terminals at the handles, and

Electric Flat Iron.

large saucepans are made on the same principle. By avoiding soldered joints, the most frequent cause of failure of the apparatus is eliminated. Hot-plates of various sizes

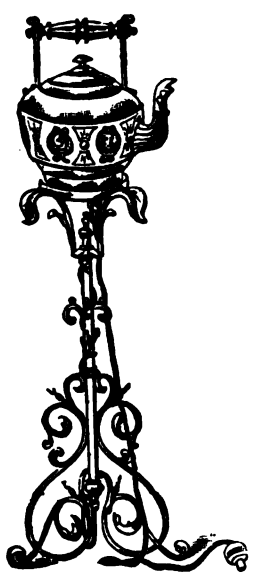
Digitized by Google

will be also exhibited, some being fitted with regulating switches arranged so that various degrees of heat can be obtained. This is not done by means of external resistances, a very wasteful method, but by putting on or off one or more of the heating resistances attached to the plates. In this way the circuits in use are always kept working at their highest efficiency. The hot-closets noticeable are most useful appliances. They consist of two electric hot-plates mounted one above the other, and fixed in a planished iron frame. The whole is placed in a handsome oak or mahogany cabinet with doors Switches are arranged to give almost any heat required for keeping

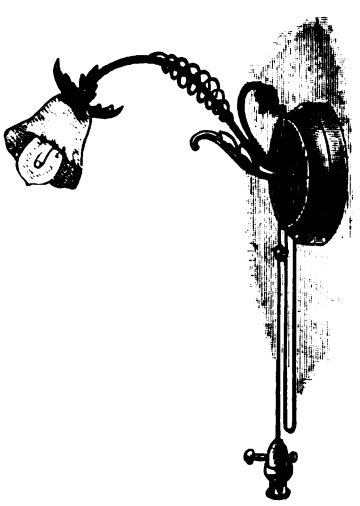


Electric Radiator.

food warm. These hot-cupboards are more suitable for dining-room use, and we understand that a number are already in use, particularly in France, where the new system of heating and warming by electricity is much appreciated. A current of six amperes is sufficient to keep the hot-closet at the proper temperature, and often half of this may be switched off when only pastry is to be kept warm. If the cost of using this arrangement were twice as much, many who could afford to use it would still do so on account of its being so convenient, cleanly, and useful. There is nothing in use at the present time which can compare in any way with



Electric Heater on High Stand with Kettle.



Electric Cigar Lighter with Lamp and Bracket.

this hot-cupboard. Gas is out of the question in the dining-room, spirit is costly and dangerous, and hot-water dishes are only a troublesome makeshift. Messrs. Crompton inform us that they have orders on hand for a number of hot-closets, some of which are of large size. It is probably in warming arrangements of this description, where electricity can beat all its competitors, that most business will at first be done. Heating apparatus will be represented by radiators of various kinds and sizes. Small radiators, suitable for small rooms or as auxiliaries in warming large ones, as also large heaters requiring as much as 10 amperes to fully heat them, will be on view. Small electric heaters are now being used in bedrooms for a couple of hours or more before retiring to rest. They take the chill off the atmosphere, and do not burn or vitiate the air in doing so. The electric heater may be placed close to the bed with perfect safety, and for this reason it is possible to feel warmer with the production of far less heat than would be required with the fire at the other end of the room. It may be mentioned that large heating chambers are now being made to dry wheat for South America, where fuel is dear but water power abundant. Other warming and heating arrangements, such as laundry irons, which appear to be coming rapidly into use, billiard irons, etc., will be exhibited on this stand. With regard to electric power, motors of various powers will be seen at work driving fans, coffee grinders, sewing-machines, etc. In this connection a new gear will be shown with a Cuttris motor, which makes the application of small motors to sewing-machines a simple matter. The motor is fixed on a tilting bedplate, so arranged that when a lever is pulled down by the pressure of the operator's foot the motor is tilted so that its pulley (provided with a rubber or leather covering for friction drive) is brought up to the sewing-machine wheel and drives it. The action of bringing the motor into position switches on the current, and the reverse action cuts it off. A brake is at the same time applied to the machine, which stops it at once, but the motor being released, the armature is allowed to run free.

Electric Urn.

This is a good arrangement, and its completeness recommends it. It is particularly good for alternating currents, as the motor starts free. In addition to the above there will be exhibited incandescent lamps of various candle-power, hammered iron fittings, and the new safety connector. The latter will be shown applied to the cooking and heating apparatus and for electric lighting purposes.

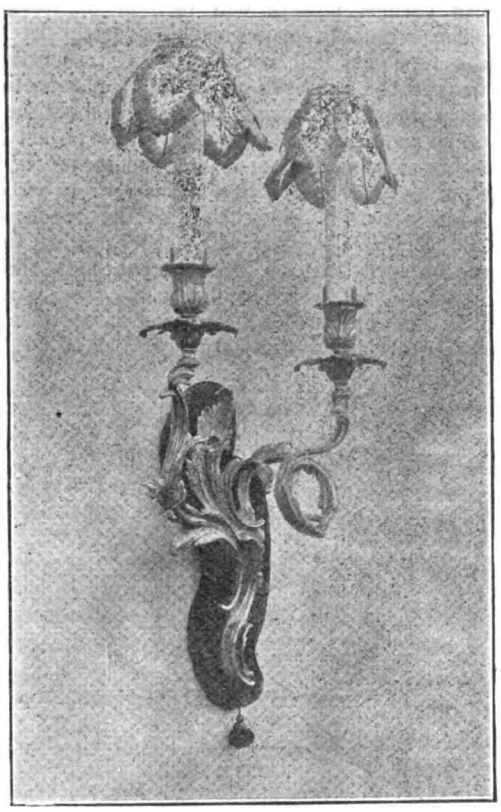
Messrs. Ronald A. Scott, Limited, of Acton-hill, W., will exhibit both finished dynamos and dynamos in course of construction, together with search-light gear. Apart from this a search-light will be fixed and operated from the roof of the building.

Messrs. Rashleigh Phipps and Co., of 102, Oxford-street, W., have been allotted a separate room on the first floor, where a tasteful selection of artistic electric light fittings will be shown, besides a large variety of electric heating, cooking, and ventilating apparatus, all of which will be shown in action. In connection with these the latest developments of electricity as applied to domestic use are made manifest. Cooking demonstrations will be given daily, at which the value of cooking by electricity will be fully displayed. The electric curling-tongs heater should prove of especial interest to the fair sex, who alone are able to appreciate the luxury of curling tongs heated without any of the blackening which is produced by other methods of heating this adjunct to a lady's toilet.

The Waltham Electrical Engineering Company, of Great Chapel-street, Westminster, S.W., will display a combina-

Digitized by Google

tion bracket fitting, of which an illustration is annexed. The fitting is highly chased and is fitted with the firm's new tassel switch and sliding connections. This combination is mounted on slate and other insulating material. It will be seen that this arrangement entirely dispenses with screws through the bracket, and allows of the bracket being lifted off the base without breaking any joints. The fixing is very rigid and makes sure contact. The working parts are concealed from view in the base, the tassel only being visible, and each successive pull of which turns the light alternately on and off. The tassels and plush mounts are made in any colour to suit existing decorations of the room. This fitting, with others of the firm's own make, may be seen on the walls of the refreshment-room.



Combination Bracket Fitting.

Messrs. Strode and Co., of 188, Piccadilly, W., will show a variety of fittings. Among these may be mentioned a wrought-iron dining-room sliding-shade light, and four new-pattern electroliers. In the centre of the stand will be arranged their bronze group of "Victorious Cupid" adapted for electric light. They will also show other bronze figures, and silver and gilt candlesticks of different patterns (some antique copies) fitted with electric candles, etc. Other exhibits will comprise several novelties in cast and wrought brass and silver wall lights, and a few ordinary wrought-iron pendants suitable for halls, etc. A showcase will also be found containing many different kinds of incandescent lamps for different purposes, clear, and coloured, and frosted, and many combinations of colour for fancy twisted lamps (in small bulbs, the peculiarity of which is that they can supply 110-volt lamps in same bulbs as 50 volts by old method). A few new patterns in table standards, fitted with small silk shades, etc., and one or two handsome French (Louis XV., XVI.) gilt sconces will likewise be found at this stand. The foregoing, with a selection of switches, sockets and plugs, ceiling roses, etc., will complete the exhibits, with the exception of pieces of work which have gained first prize at previous exhibitions.

Messrs. Pyke, Harris, and Co., Limited, of 34-36, New Tothill-street, Westminster, S.W., will display high-pressure apparatus and conduct various experiments with them. These will include the following: (*a*) Illustrating various degrees of illumination produced in vacuum tubes under similar inductive influence, the gaseous vacuum being different in each case. This experiment is worked by their inductive method of parallel coupling. (*b*) Showing the bearing of various degrees of exhaustion of two vacuum tubes, in one of which the current is passing and the other lit by approximation thereto. (*c*) Showing the varied brilliancy produced in vacuum tubes connected in series, each being of a different degree of exhaustion. These tubes are numbered similarly as regards their relative degrees of exhaustion as those in experiment (*a*). It will be noticed that tubes of the degree of exhaustion which in experiment (*a*) gave the most satisfactory results, in this case are the least brilliant. (*d*) Sundry other experiments. It has hitherto not been possible to work any considerable number of vacuum tubes from one generating source, as a tension sufficiently high could not be obtained suitable for working a very large number in series. The vacuum tubes are lit by parallel connection, which is effected by their method of interposed condensers, the E.M.F. employed being about 100,000 volts; but although this current is of so high a tension there is no danger from it, as its quantity is so very small. The high-tension transformer (Pyke and Harris's patents) shown depends for its insulation and cooling on the circulation of a dehydrated liquid insulator, and can be worked continuously without fear of heating or damage to insulation, and may be operated anywhere by connection with the ordinary alternating-current electric light wires. Another exhibit is a small "combination" transformer (Sir David Salomon's and Mr. L. Pyke's patent) which lights three tubes with bunch electrodes, specially constructed for heavy discharge, the coupling being by the firm's parallel inductive method. The final exhibit is an alternating-current dynamo which is designed to work on the inductor principle, primarily designed by Faraday; it embodies the following advantages: both the inducing and the induced current coils, together with the inducing magnet and its cores, are stationary, and the closed magnetic circuit ensures a larger amount of magnetism in comparison with the exciting current.

Messrs. Paterson and Cooper, of Pownall-road, Dalston, N.E., will show, among other exhibits, an interesting model of Penn and Lowndes's patent armature which will commend itself to builders of dynamo machinery. The novelty consists in corrugating the armature plates, rendering them perfectly rigid, and ensuring a good drive. Being self-supporting, the objectionable notches and bolts or ribs which are the cause of sparking and armature heating in so many machines are dispensed with.

THE BOARD OF TRADE STANDARDS AND STANDARDISING LABORATORY.

The recent official adoption of certain electrical standards for providing arbitrary units to which all electrical measuring instruments in this country may be—and all such as are used commercially should be—referred, has very naturally attracted considerable attention on the part of electrical engineers, as well as many of the general public, who wish to know something of the arrangements and details that have been employed in fixing the standards and finally settling the units upon which all our electrical calculations are based, and we therefore think it desirable to publish some particulars of the laboratory and instruments at Whitehall which, under the rule of the Board of Trade, now stand at the head and front of English electrical measurement. In carrying out this proposal, we have to acknowledge the ready assistance and courteous goodwill of the chief officials, Major Cardew and Mr. J. Rennie, to whom we are indebted for the illustrations and details contained in the article.

The object of such a laboratory as that under notice may be considered as twofold. In the first place, it constructs, with the utmost possible care, not only the arbitrary standards which are taken as the units of measurement, but also maintains methods by means of which these units may be at any time verified or reobtained; and, in the second place, it provides facilities under which instruments of a commercial type constructed outside may be properly tested as to their fitness for use and consequent authorisation for service under Parliamentary powers.

Both these objects are carried out at the Whitehall laboratory, as will be seen after reading this article, and the equipment for the duties thus involved is of a nature

Digitized by Google

and completeness probably not to be found in any other country whatever.

For the purposes of laboratory work it is obvious that not only must the sources of such current as may be required in testing, etc., be reliable, but it is necessary, in addition, that they should be absolutely steady. The mains of at least two electric light companies pass along the street outside the Whitehall offices, but it has been thought advisable to depend entirely upon plant erected on the premises, not only to be perfectly sure of obtaining current at any time and always, but also to allow of greater variations in current requirements with absolute ease of regulation after any desired manner.

The generating plant thus erected comprises a 6-h.p. Otto gas-engine, by Crossley Bros., driving by means of belts one or other of two Kapp dynamos, built by Messrs. Johnson and Phillips. The latter are designed respectively to give 38 amperes at 130 volts, with a speed of 1,100 revolutions per minute, and 200 amperes at 12·5 volts with a speed of 950 revolutions.

From these machines current is taken to a battery-room containing two sets of E.P.S. cells, 54 in each, and four very powerful Crompton-Howell 61-plate cells for heavy discharges. Switchboards are provided both in the engine and battery rooms for measuring and connecting up, etc. To get a more equal discharge from the Crompton-Howell battery, the current is taken in each case from the centre of the cell instead of one end.

The battery-room is connected directly, by means of a concentric cable, with the "verification" room, where instruments intended for Board of Trade testing with a view to official sanction undergo a very complete series of tests, both electrical and mechanical.

Very heavy copper-strip connections are also led from the Crompton-Howell battery—the cells of which may be coupled either in series or parallel—into the "standards" room, close adjacent, and are there connected with a large Ferranti concentric main running round two sides of the room. From this main cable connections are taken downwards to the "sub-standards" mounted on benching round the walls. Before entering the standards room, however, one of the copper-strip mains is cut in such a way that adjustable carbon resistances may be inserted so as to vary the current passing.

The remaining machinery used for developing current is placed in one of the basement rooms, and includes a B_2 Victoria motor coupled direct to an alternating machine of very special type, constructed by the Brush Company, and arranged with a large number of different combinations both in the field and armature. From a pulley, mounted on the common shaft of these two machines midway between them, is driven with belting a C_2 Victoria high-pressure continuous-current dynamo giving 2,000 volts. When it is desired to run the alternator, this belting is thrown off the motor which is run from the battery; if the high-pressure continuous-current machine is required the belt is slipped on to the pulley again, the alternator fields are cut out of circuit, and its armature then runs as a fly-wheel on the motor spindle.

A number of different transformers are used in obtaining various pressures and periodicities: among them may be cited two of the Brush type, 2,000 watts each; one by Ferranti, for potentials ranging up to 10,000 volts; a Westinghouse, up to 2,000 volts; and a smaller one of the Brush type giving 40 amperes at 100 volts, or 8 amperes at 400 volts.

(To be continued.)

THE INSTITUTION OF CIVIL ENGINEERS.

The council of the Institution of Civil Engineers invites original communications on the subjects included in the following list, as well as on any other questions of professional interest. This list is to be taken merely as suggestive, and not in any sense as exhaustive. For approved papers the council has the power to award premiums, arising out of special funds bequeathed for the purpose:

The arrangement of boilers and engines best adapted for electric light stations under different conditions. Steam locomotion for passenger traffic on common roads. The application of oil and gas engines to tractive purposes on tramways and on common roads, and to marine propulsion. The losses that occur in gas-engines and means for reducing them, with special reference to "after-burning." The relative merits of the several cycles in gas-engines. The theory and development of the compound steam turbine. Mountain railways: their laying out, construction, and working by cables, rack engines, etc. The buoying and lighting of tidal rivers and estuaries. The purification of sewage by filtration, precipitation, electrolysis, and otherwise. The theory and practical working of single and multiphase alternate-current motors, illustrated by examples of existing installations. Alternate *versus* continuous electric currents for (*a*) electric lighting and (*b*) transmission of power. The forms of electrical conductors for lighting, stationary power, heating, and tractive purposes. The utilisation of electric lighting plant during hours of small demand. Electric lighting and haulage plant in mines and collieries. The application of water power, and its transmission to a distance by electricity. Electrical motors for (*a*) inland navigation and (*b*) ocean vessels. The use of electrical motors for driving machine tools in engineering workshops. The effect of small quantities of impurities in commercial copper as regards its use in electrical work. The electrolytic deposition of copper. Aluminium: its manufacture, properties, uses, and alloys. The arrangement of engineering workshops, with descriptions of modern machine tools and appliances.

From the detailed list of the awards made for original communications submitted during the past session we extract the following:

For papers read and discussed at the ordinary meetings—Telford medals and Telford premiums to James Henry Greathead, M.I.C.E., and Francis Fox, M.I.C.E (of Westminster), for their joint paper on "The Liverpool Overhead Railway." A George Stephenson medal and a Telford premium to Thomas Parker, M.I.C.E. (of Wolverhampton), for his narrative on "The Electrical Equipment of the Liverpool Overhead Railway."

WEBBER'S APEX CONNECTOR.

The annexed illustration shows the "Webber connector," as used for joining up a table-standard lamp at the apex of its shade; the flexible in such cases would hang from a ceiling rose, and be hooked out of the way when the standard is not in use. Major-General Webber claims that for such a connector, all that is really necessary for safety is to have the heads of the sockets, into which the plugs have to be pressed, made short of the surface of the

insulating disc which closes the opening into the socket. The only way to cause a short-circuit in the socket cap of his connector would be by inserting a staple in the holes, or some such determined means. The whole connector can be made of hard wood, and has no spring in it or any screwed parts, which is an obvious advantage. Major-General Webber claims that the new safety connector illustrated in our issue of the 21st inst., and brought out by Messrs. Crompton, was anticipated in several of its features by himself in January, 1893, and that to his arrangement Mr. Crompton has added a disc which revolves on its axis actuated by a spring which holds it in the position of covering the heads of the contact tubes.

COMPANIES' MEETINGS.

EDMUNDSONS, LIMITED.

The sixth annual meeting of this Company was held at 19, Great George-street, Westminster, on the 13th inst., Mr. Joshua W. Edmundson, one of the directors, presiding. The report and statement of accounts were taken as read.

The **Chairman**, in moving the adoption of the report, congratulated the shareholders upon a satisfactory year's working. He said that although the profits for the past year were not so large as in several previous years, they were satisfactory when the great depression in trade and the large amount of competition were taken into account. He considered that the outlook for the present year was satisfactory, as they had a larger amount of work in progress than was the case at the same time last year, including, among other installations, the lighting of Warwick Castle, for the Earl of Warwick; Duncombe Park, for the Earl of Feversham; Elveden Hall, for Lord Iveagh; Copped Hall, for Mr. E. J. Wythes; Nidd Hall, for the Hon. H. E. Butler; Wood Hall, for Mr. J. W. Hutchison; and the new asylum for Sunderland. An important contract had also just been signed for lighting a portion of the town of Shrewsbury, provision being made in the first instance for 5,000 lights, and the directors hoped they would be able to extend the Company's operations in this class of work.

The report and accounts were adopted, and a resolution was passed directing the payment of a dividend at the rate of 6 per cent. per annum on both preference and ordinary shares.

Mr. Henry Wigham, the retiring director, was re-elected, as were also the auditors, Messrs. May and Street.

DIRECT SPANISH TELEGRAPH COMPANY.

The half-yearly meeting of the Direct Spanish Telegraph Company was held last Friday at Winchester House, Mr. E. Etlinger in the chair.

The **Chairman** moved the adoption of the report, and said that so long as trade was depressed they could not expect their returns to be very high. The actual decrease in the receipts was £868, against which there was a saving of £284 in debenture interest and £43 in working expenses. Quite recently there had been a marked increase in traffic, and things seemed to be better. It looked to him as if trade had made a start upward. It might be due to the settlement of the tariff in America, and, as far as the directors knew, things were reviving in American trade.

Mr. J. D. Pender seconded the adoption of the report, which, after some discussion, was agreed to.

COMPANIES' REPORTS.

BRUSH ELECTRICAL ENGINEERING COMPANY, LIMITED.

Directors: J. B. Braithwaite, jun., Esq. (of Messrs Foster and Braithwaite), chairman; Arthur Ayres, Esq., M.I.C.E.; Aymor H. Sanderson, Esq.; Colonel Frederick George Steuart; B. H. Van Tromp, Esq.; Edward Woods, Esq. (past-president, Institution of Civil Engineers). Joint managers: John S. Raworth, M.I.E.E.; R. Percy Sellon, M.I.E.E.

Fifth annual report to be presented to the shareholders at the general meeting of the Company to be held at Cannon-street Hotel, London, E.C., on Monday, October 1, 1894, at 3 p.m.

The directors herewith submit the balance-sheet and profit and loss account for the year ended June 30, 1894. The profit and loss account shows a gross profit of £57,157. 19s. 4d. After deducting general charges, maintenance of buildings, plant, and patents, interest on debenture stock, and sundry costs of removal, which the directors consider should be written off the year's profit, there remains a net balance of profit amounting to £27,280. 12s. 1d., to which must be added the sum of £815. 5s. 3d., the balance brought forward from last account. After providing the full dividend on the 6 per cent. preference shares for the year, and an interim dividend at the rate of 5 per cent. per annum which has already been paid on the ordinary shares for the half-year ended December 31, 1893, the directors recommend that a further dividend, at the rate of 5 per cent. per annum, be paid on the ordinary shares for the six months ended June 30, 1894, leaving £3,788 9s. to be carried forward. During the year the sum of £3,710. 13s. 7d. has been expended on the purchase of additional plant and extensions at the Loughborough works, where the whole of the regular home manufacturing work of the Company is now concentrated and carried on. The volume of business which the Company has been called on to undertake during the year is again in excess of that in any previous period of its existence. The prevalent industrial depression has, however, brought with it increased competition and a general fall in prices, with consequent diminution in the rate of profits obtainable. The Company's Vienna factory has yielded improved results during the past year, and shows a fair return upon the capital employed. Important central-station contracts have been successfully carried out, and others are in course of execution. The glow lamp department has during the year largely increased its output, and is now manufacturing at the rate of half a million lamps per annum. The Australian branch of the business has laboured under great disadvantages, arising out of the financial crisis through which the colonies have recently been passing; under these circumstances the directors are glad to be able to state that the bad debts incurred during the year amount to less than £50, and consider that great credit is due to the careful management with which the business has been conducted. The works of the Company are at present fully employed, and the prospects for the coming year are satisfactory. The progressive change in the character of the industry from the lighter class of electrical engineering involved in numerous and isolated installations to the heavier and more considerable works following upon the extension of electricity supply from central stations, is undoubtedly favourable to this Company. The contract with the City of London Electric Lighting Company for the supply and erection of generating plant and accessories for public and private lighting in the City of London has made satisfactory advance during the year. Contracts have also been entered into with the County of London and Brush Provincial Electric Lighting Company for the supply of plant and equipment of central-station undertakings for the districts of St. Luke's, Wandsworth, and elsewhere. Mr. Arthur Ayres, M.I.C.E., has accepted a position upon the Board to fill the vacancy created by the death of the late Duke of Marlborough. Mr. A. H. Sanderson and Colonel F. G. Steuart retire by rotation, and, being eligible, offer themselves for re-election. The auditors, Messrs. Cooper Bros. and Co., also retire and offer themselves for re-election.

BALANCE-SHEET, JUNE 30, 1894.

CONTRACTS FOR ELECTRICAL SUPPLIES

CONTRACTS OPEN.

London, W.—The Great Western Railway Company invite by October 8 tenders for the supply, among other stores, of india-rubber goods, telegraph instruments, telegraph apparatus, copper wire, G P. wire, etc., telegraph ironwork and tools, telegraph drysalteries, and arc light carbons.

Stroud.—Tenders are invited for supplying, fixing, and maintaining fire-calls and telephones for the volunteer and Local Board fire brigades, for the Stroud Local Board, in accordance with the specification prepared by the surveyor, which may be inspected at his office. Tenders, marked "Tender for Fire-calls," should be sent to Mr Percy Witchell, clerk, by October 2.

St. Pancras.—The Vestry are prepared to receive tenders for the following works in connection with their new central station at King's-road, Camden Town, and several sub-stations: main switchboard, electrical instruments, etc., motor transformers and accessories, wiring and lighting certain buildings. The drawings can be inspected, and specifications, schedules of quantities, and general conditions can be obtained at the offices of Prof. Henry Robinson, 13, Victoria-street, Westminster, on payment of 5s. Tenders are to be sent in by Thursday, October 11.

South Shields.—The following tenders are invited for the supply and erection of the following plant, for the Corporation: Section A—boiler-house plant, including boilers (marine type), fittings, pipes, chimneys, etc. Section B—pump-house plant, including double-acting, slow-speed, circulating and feed pumps, cast-iron tank, pipes, and fittings in connection therewith. Section C—engine-house and sub-station plant, including 100 and 25 kilowatt steam alternators, with double or triple compound engines, steam exciter, circulating pipes, switchboard and instruments, sub-stations, and transformers. Section D—underground work, including rubber-covered cables, cast-iron pipes, boxes, switches, and trenching. Section E—arc lamps, lamp-posts, switches, and transformers. Section F—meters. Firms tendering are at liberty to tender for any section or sections, or for the whole of the sections, but not for part of a section. Copies of specification, including plans, conditions of tender, and contract, can be obtained at the Borough Electrical Engineer's Office, South Shields, on and after 17th inst., on payment of £3. 3s., which sum will be returned on receipt of a *bonâ fide* tender. Tenders, sealed and marked "Tender for Electric Lighting," to be delivered to Mr. J. Moore Hayton, town clerk, Court Buildings, South Shields, by October 31.

BUSINESS NOTES.

Portsmouth.—The Sailors' Home is to be lighted electrically.

Belfast.—The premises of the Cornhill Cloth Company are to be lighted by electricity.

Shoreditch.—The Vestry have shelved the electric lighting scheme for six months.

Hull.—The post office is to be lighted electrically, as are St. Mary's and St. Charles's Churches.

Kingswood.—The Local Board are talking of extending the electric lighting of the district at some future time, but nothing is to be done at present.

Eastern Telegraph Company.—The Board announce an interim dividend of 2s 6d. per share for the quarter ended June 30, payable on October 15.

Steamer-Lighting.—Messrs. Ramage and Ferguson, of Leith, have launched a passenger and cargo boat, the "Sofia" for the Eastern Mediterranean trade. She is lighted electrically.

Stroud.—The Board of Health are advertising for tenders for providing electric calls for both the volunteer and town fire brigades, in accordance with the surveyor's specifications.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending 23rd inst. amounted to £955, as compared with £687 in the corresponding week of last year.

Fulham, S W.—The Fulham Vestry have adopted the Electric Lighting Acts, and have decided to provide all the necessary plant for street-lighting and the supply of private consumers.

Western and Brazilian Telegraph Company.—The receipts of the Company for the past week, after deducting 17 per cent. payable to the London Platino-Brazilian Company, were £3,598.

Gas-Blowers.—Mr. H. F. L Orcutt, of 145, Cannon-street, E.C., has issued an illustrated list of gas-blowers and hardening and melting furnaces made by Messrs. Ludwig Loewe and Co., of Berlin.

Newport (Mon.).—The question of lighting the free library by means of electricity has been referred by the General Committee to a sub-committee. The estimates showed a total annual cost of £101. 7s.

W. T. Henley's Telegraph Works Company.—This Company are making the armoured and unarmoured cables for the Glasgow Corporation's electric lighting extensions, which we hear are considerable

Macclesfield.—Mr. W. R. Brown, Mill-street, is lighting Messrs. Felton's Hovis Flour Mills electrically There will be about 150 lights. The premises of Mr. R. Robinson Brown, draper, are also to be fitted up by him.

Store-Lighting.—The Indestructible Ignition Tube Syndicate, Limited, of 100c, Queen Victoria-street, E.C., have just completed an installation at Everett's Stores, Walthamstow. The lamps comprise 16 arcs and 16 incandescents.

Acton.—The Works Committee have reported to the Local Board that they had deferred to their next meeting the consideration of two letters from electrical engineers as to the proposed transfer of the Board's electric lighting order.

Fort Augustus.—Water power has replaced steam power for the electric lighting of the monastery at Fort Augustus. The water is led from the River Turiff to a dam about three-quarters of a mile distant, and the turbine is designed for 45 h.p.—probably the most powerful of the kind in Scotland.

Lymington.—In discussing the question of the lighting of the street lamps some of the Town Council have suggested the introduction of the electric light, Admiral Earle pointing out that many towns smaller than Lymington had the electric light, and it was found to effect a saving for the ratepayers.

Appointments.—Two assistants to Mr. J. E. Stewart, the Derby borough electrical engineer, have been appointed, the chief being Mr. Gwerrier and the second Mr. Lister. Mr. H. Street, of the Exeter Electric Light Company, has been appointed assistant to Mr. T. Wilmhurst, the Derby borough electrical engineer.

City and South London Railway.—The receipts of the Company for the week ended September 23 were £835, against £775 for the corresponding week of 1893, or an increase of £60. The total receipts for the current period of the present half-year amount to £10,237, as against £9,681 in the corresponding period of 1893.

Award.—Messrs. E. Green and Son, Limited, of Manchester, Wakefield, and New York, have again received the highest award for their improved fuel economiser, the diploma of honour having just been granted to them at the Antwerp Exhibition. In all, 16 medals and awards have now been gained by this firm for their apparatus.

Brechin.—There has just been made to Brechin, through Councillor Laing, an offer by Mr. Robert Duke, of the firm of Messrs. D. and R. Duke, Denburn Works, to supply from the dynamo of their works current to light St. Ninian's-square, the improvements of which are now almost completed. The town will, of course, have to bear the cost of erecting the lamps, etc., for the installation.

Poplar, E.—The Works Committee of the Board of Works have recommended that a circular should be issued to and enquiries made from residents and manufacturers and the trustees of public buildings in the district asking if they would take electric light, if established by the Board, at 6d. per unit for lighting and 4d. per unit for power. Mr. Ben Johnson moved the adoption of the recommendation, which was carried.

Digitized by Google

Bacup.—An application from Mr. Alex. Wright has been submitted to the Town Council for permission to stretch two wires (together) across Burnley-road, from the Liberal Club to his new office opposite, to supply his office with the electric light. It was resolved that Mr. Wright be informed that the Corporation could not consent to overhead wires for electric lighting purposes, but that such wires must be laid underground.

Anglo-American Telegraph Company.—At a meeting of the Board of Directors, held on Friday last, it was resolved, after placing £6,000 to the credit of the renewal fund, to declare an interim dividend for the quarter ended September 30 of 9s. per cent. on the ordinary stock and 18s. per cent. on the preferred stock, less income tax, payable on November 1 to the stockholders registered on the books of the Company on September 30.

Brighton.—At the beginning of the month the Lighting Committee of the Town Council held a meeting at which a letter was read from Mr. H. J. Burgess, suggesting that two arc lamps should be erected at the bottom of New England-road during the time the drainage works are being carried out there. It was resolved that the committee deem it inexpedient at present to adopt the suggestion. This has now been confirmed by the Town Council.

Carbon Syndicate, Limited.—This Company has been registered with a capital of £100,000 in £1 shares. The object is to carry into effect an agreement with Mr. C. P. Shrewsbury and others, and to carry on business as manufacturers of carbon plates, slabs, rings, crucibles, rollers, bars, rods, pipes, and other articles for electrical and electrolytical and other purposes; as electricians, electrical engineers, metallurgists, colliery owners, metal founders, fitters, etc.

Luton.—On the motion of Councillor Wilkinson, seconded by Councillor Dillingham, the following motion has been unanimously passed: "That the Highways and Lighting, or a specially appointed committee, do consider and bring up a report upon the question of applying for and ultimately obtaining a provisional order for the supply of electricity for public and private purposes in the borough of Luton, and that they ascertain the cost of obtaining such order and supply."

Stirling.—A special meeting of the Stirling Town Council has been held to consider whether they should apply this year for a provisional order to supply the burgh with the electric light. Bailie Lawson said it was a great undertaking, and he did not think the Council should go into it. The better way, he thought, would have been to allow one of the companies to get the order. It was, however, agreed to proceed with the application, Bailie Lawson and Councillor M'Diarmid dissenting.

Manchester.—The Moss Side School Board have received a report from Mr. J. Nasmyth, showing the comparative cost of lighting the Board's new schools by gas and by electricity. The Chairman moved and Dr. Fraser seconded, that the recommendation of the Sites and Buildings Committee be adopted—namely, that a system of electric lighting by private installation be adopted. As, however, the desire was expressed to discuss Mr. Nasmyth's report at a full meeting of the Board, an amendment was adopted on the motion of the Rev. Dr. Neilson, seconded by Dr. Baynes, that the recommendation be considered at a future meeting.

Altrincham.—An installation has been put up on the premises of Mr. J. B. Wilson, Station-road. The motor comprises a 2-h.p. gas-engine, which drives a dynamo capable of supplying 40 incandescent lamps. The gas-engine has been provided and fixed by the National Gas-Engine Company, of Ashton-under-Lyme. Mr. Joseph Bickerton, Albert-road, Hale, who is connected with the firm named, personally superintended the whole of the arrangements. The establishment is furnished with about 40 lamps. The Altrincham Electric Supply propose commencing the supply of electric light in the Altrincham and Bowdon districts in October. The price which will be charged is 8d. per unit, subject to a discount.

Sunderland.—The Corporation has issued circulars to tradesmen and private residents informing them that the Corporation will be in a position towards the end of the present year to supply electricity in the following streets and thoroughfares: Dunning-street, High-street West (from Villiers-street to Hind's Bridge), Union-street and Waterloo-place, Bridge-street, North Bridge-street (to Wheat Sheaf corner), Fawcett-street, John-street, St. Thomas-street, West Sunniside, and Borough-road (from Norfolk-street to Crowtree-road in Holmeside). The circular affords intending customers every information as to charges. The Corporation strongly impress on customers the importance of having the work of installation done by thoroughly competent contractors.

Fareham.—The award of the arbitrators (Messrs. J. A. Fleming and A. H. Preece) in the matter of the purchase of the Fareham Electric Light Company's works by the Local Board, has been received by the latter body. The arbitrators place the present value of the undertaking as a going concern at £4,866. In addition to this, the transfer, if proceeded with, will involve the spending of £700 on the purchase of land, £1,000 for laying the wires underground and for obtaining an additional engine, £175 for arbitration and loan expenses, and a small item connected with the laying of the wires and the cost of a few new standards will make the total amount required about £7,000. Formal application is to be made to the Local Government Board for power to borrow this amount.

Swansea.—In connection with the report of the Streets Committee of the Swansea County Council, Mr. F. Rocke said that a letter had been received from the gas company declining to light the four lamps which have been erected on the road leading from Upper Bank to Llansamlet on account of the great distance apart thereof. It appeared that the gas company insisted upon their rights to have the lamps 50 yards apart. Incidentally, Mr. Rocke asked what was being done with reference to the important question of electric lighting, in which the ratepayers evinced considerable interest. Many of them were anxious to use the light in their premises. Alderman Richards said a meeting of the Electric Lighting Committee had been held, and there was a probability of the scheme under consideration being put into effect.

Bath.—The Surveying Committee have been considering the subject of the electric light. Alderman Bright thought the electric lighting company ought to switch on the current a little earlier in the evening for the lighting of the streets. They had had several nights lately when if it had not been for the lights in the tradesmen's shops, Southgate-street would have been in darkness. Alderman Sturges explained that their agreement with the company provided for an average lighting throughout the year of 10 hours for each night It was found impossible, however, so to arrange the lighting as to make this average cover the darkness all the year through, and he admitted the justice of Alderman Bright's complaint, which was referred to the Lighting Committee. Mr. Bartrum remarked that it was of no use for the matter to go to the Lighting Committee unless they were prepared to pay more money.

Ulverston.—The clerk to the Rural Sanitary Authority has read the correspondence with the urban authorities of Ulverston, Dalton, and Grange on the subject of the electric light, from which it appeared these Boards had appointed deputations to confer with the special committee of the Authority respecting the intended application to the Board of Trade by the Windermere District Electric Light Supply Company for an order empowering them to supply electricity for public and private purposes in this district. Mr. Holme suggested that if it would not then be too late to take any action that might be necessary, the subject should be deferred for the consideration of the new District Council. Mr. Harrison thought it would be as well to give formal notice of opposition, so that the Authority might have a *locus standi*. Mr. Mason: The proposal at present is simply that this conference be held. On the motion of Mr. Haines, seconded by Mr. Dickson, it was resolved that the clerk arrange with the other bodies for a suitable day for the conference.

Cambridge.—During the vacation considerable additions have been made to the supply of current for house, shop, church, but chiefly college lighting. Ten colleges are connected, and consume large amounts of energy, whilst in Caius and Sydney the light has been installed throughout in place of gas, including courts, staircases, and men's rooms. The new Sidgwick Hall of the ladies' college at Newnham is wired throughout, and current will be available by the beginning of the term. Holy Trinity Church has adopted the light, and the demand for private house-lighting is largely on the increase, a mile of main being laid in the growing residential district of Newnham. The wiring has been executed by the local firm of Messrs. Baily, Grundy, and Barrett, Limited. Street-lighting is in abeyance beyond a limited amount, the gas company having a contract running for some little time to come. To meet the increased demand a new Parsons steam turbine alternator is being fixed for the winter months. The sub-station equipped by Messrs. Parsons and Co. is rapidly replacing the house-to-house transformers.

Country-House Lighting.—Mr. R. Clifford Smith, of Ashford Hall, well known in the Midlands, has decided to have his mansion lighted throughout by electricity. The work has been entrusted to Messrs. Drake and Gorham. No doubt the fact that Chatsworth, the well-known seat of the Duke of Devonshire, which was designed and carried out under the personal supervision of Mr. Bernard Drake, was a great factor in deciding to whom the work should be given. The plant will consist of a dynamo driving a water turbine, and a storage battery of the D.P. type will be installed to provide current when the plant is not running. This battery will permit of double or treble rates being taken from it for short periods without the slightest deleterious effect—a matter of some importance in the case of country houses. The installation will contain a Neville automatic accumulator switch to prevent any possibility of the current discharging itself through the machine, and will be provided with many other conveniences in connection with mansion-lighting, in which Messrs. Drake and Gorham have had such a large experience.

Bilston.—The question of the lighting of the market house having been referred to the General Purposes Committee by the Estates Committee, the Bilston Town Commissioners were recommended to accept the tender of Messrs. Fowler, Lancaster, and Co., Limited, of Birmingham, who offered to do the work for £550. Mr. Davies, in introducing the recommendation, said that the tender of Messrs. Waring and Co., of Liverpool, was accepted as being the most suitable, but subsequently that firm demurred to the terms of the Board. Correspondence had passed on the matter, and Messrs. Waring appeared to have given up the idea of tendering for the work, and the General Purposes Committee recommended the acceptance of the next tender, which was Messrs. Fowler and Lancaster's. It had been intimated that Messrs. Waring were willing to accept the terms offered, and they were now asked to decide between the two. Messrs. Waring's was the lowest tender. Some discussion arose upon the subject, and ultimately Messrs. Waring and Co.'s tender was accepted.

Fermoy.—The clerk has read to the Town Commissioners communications from the town clerks of Bray, Carlow, and Kilkenny

Digitized by Google

concerning the cost for electric lighting in these towns. In these places the electric lighting is run by private companies at their own risk. The town clerk, Bray, said that the cost of lighting the town, for both public and private lighting, would be about £650 a year, if the Commissioners borrowed the money. That amount he made up as follows: interest on loan of £8,000, for plant, etc., at 4 per cent., £320; wages and all other incidental expenses, £330; total, £650. The Board, having discussed the matter, came to the conclusion that putting the cost of public lighting at present, including wages of watchmen, etc., at £150, it would leave a balance of £500 to be derived each year from private consumers. The opinion of the Commissioners was that the gas company derived at least £2,000 per year from the latter source, and the clerk was directed to ask the engineers of the Kilkenny and Bray Electric Lighting Companies on what terms they would come to Fermoy to confer with the Commissioners on the subject, and prepare an estimate of the cost.

Aberdare.—A provisional order having been obtained for the lighting of the centre of Aberdare by electricity, steps are being taken to form a local company for the purpose of carrying the project into execution. At a preliminary meeting held a short time ago, a deputation was appointed to visit Pontypool to inspect the machinery and mode of lighting there. The deputation, which consisted of Messrs. D. Williams, high constable of Aberdare; G. George, J.P.; Thomas Lloyd, grocer; M. R. David, Rock Brewery; L. N. Williams, Cambrian Lampworks; T. Rees, Swan Hotel; D. Hughes, Boot Hotel; D. Tudor Williams; D. J. Gwyn, Metropolitan Bank; E. Arnott, Danygraig; D. P. Richards, Blaengawr, etc., were accompanied by Mr. J. C. Howell (Messrs. J. C. Howells, Limited, Llanelly), in whose name the provisional order was obtained, and Mr. P. T. Rhys, solicitor for the promoters. At Pontypool they visited the electric lighting station, where Mr. J. C. Howell, and the engineer, Mr. Stephens, explained to them in detail the working of the machinery, cost of production, etc. After dinner a visit was paid to the market place, which was lighted by electricity for the occasion.

Chester.—The Town Council on Wednesday of last week met to consider the adoption of a proposed site for the electric light station. The town clerk (Mr. Sam. Smith) read the minutes of the Electric Lighting Committee, who on September 7 considered a report of the sub-committee as to the various sites, including Frodsham-street, land adjoining the sewage works, Tramway-street, Leadworks Field, Water Tower View, the old county gaol, and Herbert's-court, Crook-street. The matter was adjourned for further enquiries until September 13, when he (the town clerk) reported that he had seen Alderman Williams, who would not put a price on his land, but suggested the Corporation should have it valued and make him an offer. Mr. T. A. Fletcher, solicitor, on behalf of the late James Parry's family, offered the Commercial Hall, Frodsham-street, containing 1,804 square yards, but he also had not put the land on a price. As to the other site in Frodsham-street, belonging to the Charity Trustees, a letter was received from the Rev. J. W. Clark, intimating that the Queen-street Chapel trustees would do all they could to discourage its use, as the proposed buildings would be "very prejudicial to them as a religious community, detrimental to their buildings, and injurious to the neighbourhood." Coming next to the Tower Field gardens, the property of the Corporation, it was suggested that there was a very suitable site adjoining Crane-street, and immediately behind the railway embankment as it would be when widened. After discussion, it was moved by Alderman Charles Brown, seconded by Mr. J. W. Huke, and unanimously resolved: "That it be recommended to the Council that the Water Tower Gardens, belonging to the Corporation, be the site for the proposed electric light generating station, and that the committee be authorised to proceed to establish the installation, submitting tenders, or terms of any proposed contract, to the Council in the usual way." Mr. W. C. Deeley, chairman of the committee, moved the adoption of the recommendation, which after some discussion was carried.

Huddersfield.—The Huddersfield County Council have approved of the following proceedings: The Rates and Rents Sub-Committee met, in accordance with the resolution of the Electric Lighting Committee of August 1, to consider the desirability of rearrangements in the charge for electricity in the following directions, or some of them—(1) reduction of rates, (2) adoption of graduated scale, (3) reduction of meter rents. It was resolved that no reduction be made in the charge for the supply of electrical energy, but that the following discounts be allowed—viz.:

On consumption exceeding for half-year.	Discount.	On consumption exceeding for half-year.	Discount.
1,000 units ...	2½ per cent. ...	2,600 units ...	6½ per cent.
1,200 ,, ...	3 ,, ...	2,800 ,, ...	7 ,,
1,400 ,, ...	3½ ,, ...	3,000 ,, ...	7½ ,,
1,600 ,, ...	4 ,, ...	3,200 ,, ...	8 ,,
1,800 ,, ...	4½ ,, ...	3,400 ,, ...	8½ ,,
2,000 ,, ...	5 ,, ...	3 600 ,, ...	9 ,,
2,200 ,, ...	5½ ,, ...	3,800 ,, ...	9½ ,,
2,400 ,, ...	6 ,, ..	4,000 and over ..	10 ,,

And in addition, if the consumption per half-year per 8-c.p. lamp (or equivalent) fixed upon the consumer's premises shall be: above 15 B.T. units, 10 per cent. discount; between 10 and 15 units, 7½ per cent.; between 8 and 10 units, 5 per cent.; between 6 and 8 units, 2½ per cent. It was decided that the revised scale of charges for meter rents as now decided upon be adopted; that the supply of electrical energy for motive and domestic purposes other than lighting be charged at the rate of 4d. per unit; and that the following revised scale of meter rents be adopted: meter and switch rental (30-watt lamps)—1 to 25, 12s. 6d. per annum; 26 to 50, 15s.; 51 to 100, £1; 151 to 200, £1. 7s. 6d.; 201 to 300, £2. 10s.; 301 to 400, £3; 401 to 500, £3. 10s. The Electric Lighting Committee met on August 29, and adopted the recommendations of the sub-committee, the reduction of the charge for electrical energy for motive and domestic purposes other than lighting to 4d. a unit to take effect as and from July 1 last. The engineer submitted applications from Mr. John Sykes, of Acre House, Lindley, and Mr. F. W. Sykes, of Green Lea, Lindley, for an extension of the main from Wellfield to their respective houses, at an estimated cost of £430; estimated revenue, £100. It was resolved that the applications be granted, and the mains extended as early as possible. It was recommended that 3,000 yards $^{7}/_{16}$ cable be ordered from Messrs. Calvert and Co, Folly Hall; and that Mr. Percy Lunn, now engaged as draughtsman at the electric supply station, be appointed junior assistant engineer at a yearly salary of £55.

Dewsbury.—The Corporation in 1891 obtained a provisional order from the Board of Trade, such order defining a compulsory area, in which electrical mains were to be laid. Although, in view of the considerable initial expenditure it would involve, it was with a certain amount of reluctance that the Dewsbury Corporation made their application to the Board of Trade, yet they felt bound, in the interests of the ratepayers whom they represent, to prevent any company setting itself up in the town as a powerful competitor with the public gasworks. The line of argument the Corporation took was something like this—if the people of Dewsbury prefer electricity for lighting purposes, why should not we supply them ourselves, and derive the benefit of their custom, rather than allow a company to come in to utilise what profits might accrue to swell the dividends paid to their shareholders? But it was not so much, perhaps, the hope of future financial gain as the fear of considerable loss of custom, that prompted the Dewsbury Corporation to take the steps they have. The Corporation are making preparations for the changed conditions, and the worst thing that can now happen to them is a mere transfer of custom from their gasworks to their electric lighting station. Of course, a new undertaking of this character could not be commenced without considerable capital, and this the Corporation provided by obtaining legal borrowing powers to the extent of £25,000. It was not anticipated at the time these powers were obtained that the whole of this large sum of money would be required, at any rate, for some considerable period. In fact, the expenditure, so far, does not amount to half this sum; but in municipal, as well as in domestic matters, it is always well to be prepared for an emergency. The new lighting station is a substantial structure, consisting of engine-room, boiler-house, and battery-room. It is situated on the site of the old gasworks in Bradford-road, and has been erected at a cost of a little over £3,500. Mr. Mark Scott, of Earlsheaton, is the contractor. Two 100-kilowatt machines and one 50-kilowatt machine have been supplied by Messrs. Crompton, London, the dynamos being coupled direct to the engines. A local firm—Messrs. J. and J. Horsfield—have put in the boilers. The mains have been laid by Messrs. Siemens Bros. and Co., London, their contract amounting to £3,856. The area in which the Board of Trade, by their provisional order, made it compulsory for the Corporation to lay mains comprises the Market-place, Daisy-hill, Long-causeway, Church-street, Northgate, a portion of Bradford-road, and Wellington-road to the top of Nelson-street. The low-tension three-wire system is the system that has been adopted. Mr. W. H. Preece devised the scheme, which, partly under his own superintendence, and partly under the superintendence of Mr. A. K. Greener, A.I.E.E., has now almost been carried out. It is the intention of the Corporation to supply through meter at 6d. per unit.

Hampstead.—The Electric Lighting Committee have presented two reports to the Vestry, in which they stated that they had appointed Messrs. W. Bathurst, O. Hansom, and E. Sayer as assistant engineers at the electric lighting station at a salary of £104 a year each, such appointments to be determined by one month's notice at any time; E. Kerrison as storekeeper at a salary of 25s. a week, such appointment to be subject to a week's notice at any time; and W. C. Bishop as clerk at a salary of 25s. a week, such appointment to be subject to a week's notice at any time; and that they had empowered Mr. Chattock, the engineer, to engage three drivers at £1. 10s. 4d. per week each, three firemen at £1. 9s. 2d. each, three regulators at £1. 9s. 2d. each, three trimmers, two at £1. 4s. 9d. each, and the other at £1. 5s. 8d., a fitter at £1. 18s., two labourers at £1. 4s. 9d. each, an engine cleaner at £1. 4s. 9d., and a wireman at £1. 11s. 6d. per week, the total amount of the wages, exclusive of the first engineer's salary, being £32. 14s. 11d. per week. They had also accepted the following tenders: Messrs. Radford and Co., for the preliminary supply of 50 tons of best Welsh smokeless slack coal at the electric lighting station; Messrs. Burford and Son, amounting to £57. 15s., for fitting up the offices, stores, etc.; Messrs. Maple and Co., amounting to £64. 19s. 10d., for supplying the furniture for the offices; and Messrs. Yerbury and Sons, amounting to £38, for providing an iron hurdle fence with gates at the entrance to the electric lighting station, for providing five electric bells, and for cutting through wall and erecting a new gate on public footpath adjoining, in accordance with the plan prepared by the engineer and to his satisfaction. The committee recommended the Vestry to advertise for the supply of coal to the electric supply station for 12 months, and also to effect an insurance of the station and plant. They also

Digitized by Google

recommended that the following cheques be drawn : Messrs. Yerbury and Sons, twelfth instalment under contract for the erection of the central electric supply station, as per certificate of architect, £500; Messrs. Siemens Bros. and Co., fourth instalment under contract for supplying and fixing electric lighting plant, as per certificate of engineer—viz , steam dynamos, £962. 16s., arc lamps and posts, etc., £110—£1,072. 16s. ; total, £1,572. 16s. Mr. Churchwarden Thwaites, chairman of the Electric Lighting Committee, in the course of the discussion upon the reports, said that the men would work in three shifts of eight hours each, and, though the whole of the staff would be required soon, they had only appointed for the present work three assistant engineers, three drivers, three firemen, one regulator, one lamp trimmer, one engine cleaner, one clerk, one store and time keeper, one fitter and his labourer, the wages for whom would amount to £24. 9s. 11d. per week. The idea of the committee was to work as economically as possible, but they hoped that they would soon be warranted in employing the whole staff enumerated in the list put forward by the committee.

Cardiff.—The Property and Markets Committee and Lighting Sub-Committee reported at a meeting of the Cardiff County Council on Monday having considered the subject of installing the electric light at the Town Hall and market buildings, and for this work they proposed the acceptance of a tender by Messrs. Fergusson and Co., of Cardiff, at £523. 10s. The committee also proposed that the chairman of the Property and Markets Committee (Alderman David Jones), and the chairman (Councillor Vaughan) and vice-chairman (Alderman Carey) of the Lighting Committee be sent to London to select electric light fittings for the Town Hall, etc Councillor Vaughan moved the adoption of the report, and Alderman Carey seconded, the latter remarking that it was satisfactory that a local firm had secured the contract, and pointing out there was great discrepancy in the tenders, one being as high as £1,784. Alderman Carey added that they would have the electric light in the town before long, and it was necessary to make some show in their own Town Hall, for they could scarcely ask the public to take the electric light unless they were prepared to show what could be done with it. Councillor Vaughan said that they were only waiting for some gunmetal tubing which had been ordered. All else was ready. By the end of the week the engines would be at work, and they hoped to have the light in a week or two. It was not the intention of the Lighting Committee to supply fittings. The Mayor's name was added to the deputation for the selection of fittings, and the report was adopted. In view of the early completion of the Cardiff Corporation electricity works, the Lighting and Electrical Committee have issued a pamphlet containing a few particulars for the guidance of intending users of the electric light, and they strongly recommend that the wiring of premises be put in hand at once. At the outset the committee state that the current will be alternating at a periodicity of 40 per second and the electrical pressure will be 100 volts. The price for current by meter will be 6d. per unit. After giving the forms of requisition by owners and occupiers and forms of agreement the committee give certain general conditions which are to be observed. The Corporation will provide free of cost a main cut-out and two terminals for supplying electrical energy to the consumers' premises, and also a suitable meter, on conditions somewhat similar to those of a gas company. The rental for meters will be as follows : for every 100 lights, 8 c.p., or proportion of same, £1 per annum. For cut-outs and terminals the charges will be : up to 25 lights of 8 c.p. and 16 c.p., 5s. per annum ; above 25 lights and up to 50 lights, of 8 c.p. to 16 c.p., 10s. per annum ; above 50 lights and up to 100 lights, of 8 c.p. to 16 c.p., 15s per annum ; above 100 lights and up to 150 lights, of 8 c.p. to 16 c.p., £1 per annum ; above 150 lights and up to 200 lights, of 8 c.p. to 16 c.p., £1. 5s. per annum ; above 200 lights, by special agreement. The Corporation will make the necessary connections with the service wires and meter and main cut-out at their own cost, provided the run of branch mains does not exceed 60ft., but the cost of connecting to the internal wiring shall be borne by the consumer.

PROVISIONAL PATENTS, 1894.

SEPTEMBER 17.

17668. **Improvements in connecting dry batteries without the aid of either terminals or wires.** Henry Nehmer, Ferdinand Nehmer, and Thomas Adolphus Reynolds, 27, Sekforde-street, Clerkenwell, London.

SEPTEMBER 18.

17737. **Improvements in or relating to the manufacture and insulation of electric cables.** George Hinde Nisbett, 6, Lord-street, Liverpool.

17741. **Improvements in or relating to galvanic batteries.** William Phillips Thompson, 6, Lord-street, Liverpool. (Albert Lessing, Germany.)

17761. **Improvements in electric arc lamps.** James Brockie, 28, Southampton-buildings, Chancery-lane, London.

17774. **Improvements in electrical signalling apparatus.** The Phonopore Company, Limited, and Edward Wythe Smith, Faraday House, Charing Cross-road, London.

SEPTEMBER 19.

17789. **Improved driving gear for actuating dynamo-electric machines.** George Twigden, Bristol Bank-buildings, Bristol.

17808. **Improvements in electric arc lamps.** Henry Lyon, 87, St. Vincent-street, Glasgow.

17845. **Improvements in electric arc lamps.** James Devonshire, 24, Southampton-buildings, Chancery-lane, London. (Elihu Thomson, United States.) (Complete specification.)

17846. **Improvements in electric arc lamps.** James Devonshire, 24, Southampton-buildings, Chancery-lane, London. (Elihu Thomson, United States.) (Complete specification.)

SEPTEMBER 20.

17922. **Improvements in electric arc lamps.** Michael Immler, 3, Fynes-street, Vincent-square, Westminster.

SEPTEMBER 21.

17968. **Improvements in supporting insulators for electric wires.** Lauren S. Beardsley, 38, Chancery-lane, London.

SEPTEMBER 22.

18032. **Improvements in electric stop motions for machines for preparing and spinning fibrous materials.** Edmund Tweedale, Samuel Tweedale, and Joseph Smalley, Castleton, near Manchester.

18057. **An improved carbon regulator for arc lamps.** Leon Zausmer, 97, Newgate-street, London. (Complete specification.)

NOTES.

"Professor" Preece.—Such is the title given to Mr. W. H. Preece by the *Daily Chronicle.*

An Extraordinary Complaint.—The *Globe* complains that in many of the London streets the arc lights are far too brilliant.

Electric Light and Gas.—A correspondence is going on in the *Sheffield Telegraph* on the subject of the respective merits of the electric light and the Welsbach gas-burner.

Teignmouth.—The gasworks of the Local Board are in debt to the extent of £1,160. What position would they be in if a company started the supply of electric light?

Fire.—Early on Wednesday morning a fire broke out on the premises of Messrs. Andrews and Co., electrical engineers, 15, Morsham-street, Westminster. The building was practically destroyed.

Electric Light Carbons.—It is stated that the Allgemeine Elektricitäts-Gesellschaft, of Berlin, will shortly manufacture carbons on the principle invented by Messrs. F. Hardtmuth and Co., of Vienna.

Telephony in the Austrian Army.—Provision is made in the Austro-Hungarian budget for a sum of £2,000 for 14 sets of telephone apparatus, etc., for the establishment of communication in the field.

London Gas.—A conference was held on Tuesday at Hammersmith to complain of the London charges for gas, and formulating other complaints about the form of illuminant which is now passing away from us.

Telegraphy in Mexico.—In a recent message to the local legislature, Governor Villada, of the State of Mexico, says he has devoted attention to the encouragement of public works such as the erection of telegraph and telephone lines.

An Electric Ballet.—On Monday, 15th inst., "The Carnival Electrique" will be transferred from Blackpool to the Oxford Music Hall, London. It is stated that the *finale* is a scene in which the flashing of numerous lamps is cleverly worked.

Junior Engineering Society.—The annual general meeting of this society will be held this (Friday) evening at the Westminster Palace Hotel. To-morrow afternoon a visit will be paid to the gigantic wheel works, Earl's Court Exhibition.

Telephony in Germany.—Telephonic communication will shortly be established between Berlin, Cassel, and Frankfort-on-the-Maine. On Monday telephonic connection was opened between Bremen, Berlin, and Hanover, and also between Cologne and Hamburg.

An Acknowledgment.—We beg herewith to acknowledge the strict respect paid to journalistic etiquette by *Kuhlow's German Trade of Review*, of Berlin, which constantly scissors electrical paragraphs and articles from the *Electrical Engineer*—without any acknowledgment whatever.

The "Electrical Engineer" Testing Set.—Bearing the title of the "Electrical Engineer" resistance-box and the "Electrical Engineer" galvanometer, Mr. W. Turvey, of Notting Hill-gate, has introduced a complete portable testing set, which we hope to illustrate in a future issue.

Telephony in Hungary.—The Hungarian Minister of Commerce proposes to establish telephonic communication between all the larger towns of the kingdom and Budapest. The system is primarily intended for administrative purposes, and secondly for public use. The work is to be carried out within two or three years.

Personal.—Mr. Ernst Thurnauer, general manager in Europe of the General Electric Company, of the United States, and a director of the Compagnie Française pour l'exploitation des Procédés Thomson-Houston at Paris, and of the Union Elektricitäts-Gesellschaft at Berlin, has joined the Board of the British Thomson-Houston, Limited.

Electric Lighting in Switzerland.—The new electric light station at Lotzwyl, which has been carried out by the Zürcher Telephon-Gesellschaft, Aktiengesellschaft für Elektrotechnik, is proving very successful. About 300 16 c.p. lamps can be supplied, and most of these have been taken up. Power is obtained from turbines.

Institution of Civil Engineers.—A recently issued list of members, corrected to September 6, 1894, shows that there are now on the roll of the society 19 honorary members, 1,837 members, 3,597 associate members, and 358 associates—together, 5,811. The students attached to, but not forming part of the corporation, now number 782.

Electric Traction in Hungary.—Mr. Koloman Gulàcsy has received the concession for an electric tramway between Ofner, Kettenbrückenkopf, Gachsenfeld, and Promontor. A project has been prepared by Mr. Alois Bernaczik, of Bielitz, and Mr. Max Déri, of Vienna, for an electric railway between Bielitz and Ober-Ohlisch, in Austrian Silesia.

Telephony in France.—M. G. Fribourg has published in *Le Génie Civil* some statistics as to progress of telephony in France. On September 1, 1889, there were 6,255 telephone subscribers in Paris and 5,185 in the provinces, making a total of 11,440. On May last the numbers had risen to 13,060 in Paris and 12,798 in the provinces, making a total of 25,858.

Electricity in the Transvaal.—The general manager of the Transvaal Gold Exploration and Land Company reports in connection with their new plant that the turbine has been completed, and that work is being continued on the foundations for the dynamo and electric motor. The electric transmission cable has arrived and the cable poles are being delivered.

Russian Military Electrical School.—According to *L'Invalide Russe*, the Czar has issued an order creating in St. Petersburg a military electrical school, the object of which is to prepare engineering officers for special functions where electricity is employed, to form instructors for the men in the engineers, and to study electrical inventions which may prove useful in military service.

The Trans-African Telegraph.—A Reuter's cablegram states that the first section of the trans-continental telegraph is now open as far as Blantyre, and, prior to his departure from Salisbury, Mr. Rhodes received a telegram of farewell from Mr. Sharpe, the administrator. This despatch was sent by a native operator, and was received by Mr. Gordon, a nephew of the late General Gordon, the officer in charge of the Salisbury-Tete section of the telegraph.

New Swindon.—The report of the Electric Lighting Committee was read and approved at the last meeting of the General Purposes Committee of the Local Board. The committee recommended that application be made to the Board of Trade for a provisional order for lighting the district of New Swindon by means of electric light. It has been resolved to make the necessary application, and to take all the necessary steps forthwith to carry out the recommendation.

Digitized by Google

Electric Lighting in Russia.—The central electric light station in St. Petersburg, for which Mr. Smirnhoff has obtained a concession, will be supplied with plant by Messrs. Gantert Bros., of Moscow, the Russian representatives of the Oerlikon Works, and of Messrs. Escher, Wyss, and Co., of Zurich. There will be four alternating-current Oerlikon dynamos, each of 200 kilowatts, each being driven by a vertical triple-expansion engine of 350 i.h.p., made by Messrs. Escher, Wyss, and Co.

German Electro-Chemistry. — The first annual general meeting of the German Electro-Chemical Society is to be held in Berlin to-day and to-morrow. Among the papers to be read are the following: "J. W. Ritter, the Founder of Electro-Chemistry," by Prof. Ostwald; "The Practical Utilisation of Ozone," by Dr. Fröhlich; "Experiments in the Utilisation of the Chemical Energy of Coal as Electricity," by Dr. W. Borchers; and "The Boundaries of Electrolysis," by Dr. le Blanc.

Peculiar.—Sir Augustus Harris has introduced incandescent gas lamps in Drury-lane Theatre. This is a peculiar proceeding, but the Strand Board of Works are probably accountable for it. Their Lighting Committee have recommended that the application of the Charing Cross and Strand Electricity Supply Corporation for leave to lay mains in the parish of St. Paul, Covent Garden, for the purpose of supplying electric light to Drury-lane Theatre be refused. The Board of Works have agreed to the same.

Telephony in Denmark.—Reuter states that the projected State telephone between Copenhagen and Fyen will probably be constructed during the present autumn, and credits are now demanded for the establishment of a telephonic service between Fyen, *vid* Jütland, to the German frontier. This line is intended to form a link in eventual telephonic communications between Copenhagen, Hamburg, and Kiel, from Copenhagen to Nykjöbing, on the island of Falster, and in Jütland from the German frontier to Aarhuus.

Cardiff.—The Public Works Committee of the Town Council have considered a letter read by the town clerk from Mr. Lynch-Blosse, Conway-road, objecting on behalf of himself and sister to the extension of Mr. Sidney Walker's electric works close by; also a letter from Mr. Walker, enclosing a memorial from residents of Conway-road and Severn-road who were in favour of his application. He also stated that he had gone into the matter, and found that the committee had no power to prevent Mr. Walker building on the ground selected, but the ground landlord might.

Telephony in the Eastern Counties.—The trunk telephone line which has been erected by the Post Office authorities between London and Chelmsford, Colchester, and Ipswich, has been opened for public use. A "silence cabinet" has been erected in the Ipswich post office, and three minutes' conversation may be had with Colchester for 3d., with Chelmsford for 6d., with London for 1s., and with Brighton for 1s. 6d. Connections will shortly be made through London with other great towns of the United Kingdom, and the officials have already spoken with Paris.

Electric Transmission of Power in Switzerland.—The Lucerne Municipality have appointed a commission of experts to enquire into the further utilisation of water power for the electric transmission of power for small motors. The utilisation of water power in Switzerland for the electric transmission of power is making constant headway. A large central station is being established in Wynau by Messrs. Siemens and Halske on behalf of the local authorities of Langenthal, who will charge £4 per annum for 1 h.p., and cheaper rates for larger quantities. Another station is to be erected at Rappoldingen by Messrs. Brown, Boveri, and Co. There is 2,700 h.p. available.

Where was Moses?—According to a local paper, a singular incident occurred at St. Nicholas's Church, Bristol, on Sunday. The preacher, selecting a text for the times, dwelt upon the present phase of unbelief, and spoke of one of those phases having developed a disinclination to believe anything which could not actually be seen. "Picture," said the preacher, "the blind telling us that the things around us with which we were familiar were not in existence because the blind themselves could not see them!" The preacher had uttered the words, "there are things around us which we cannot see"—when out went the electric light, leaving the place in utter darkness as there came from the preacher's lips the context—"although we are sure they are there."

A Prize Competition.—The Société Industrielle d'Amiens, 20, Rue de Noyon, Amiens, have decided upon the subjects of the competition for 1894-5: a gold medal for a mechanical or chemical generator of electricity fulfilling the most economical and efficient conditions; a gold medal for the best electric light installation at work for over a year in an industrial establishment, the installation being more economical than gas, the basis of comparison being a works having 300 to 500 burners and manufacturing its own gas; and a gold medal for a new and economical application of electro-chemistry in the district. Foreigners are allowed to compete, but all papers must be written in French. Manuscripts or machines are to be sent in by the end of April next.

Suggested French Cables.—According to Dalziel's Paris correspondent: "Now that the mission to Madagascar is being so much talked about, and the probability of a military expedition discussed, attention is once more being drawn in the Press to the fact that all the confidential communications which M. le Myre de Vilers will have to make to his Government will pass over an English cable, and stress is laid on the great harm this may cause to France. The matter is even considered so important that an agitation is being got up with the view of inducing the Government to organise independent cables all over the world, and to see if one of the great French telegraph companies cannot be induced to lay one immediately for use during the approaching military operations, which are now looked upon as unavoidable."

Electric Traction in Germany.—The Berlin local authorities have decided to call upon the Grand Berlin Horse Tramway Company to proceed at once with the work of laying a tramway from Reichenbergerstrasse to Treptow, as otherwise the project will be passed over to another company. A tramway is also to be constructed in Berlin from the Wienerstrasse *vid* Wienerbrücke and Köpenicker Weg to Treptow. The Berlin Municipality have sent a deputation to Dresden to see Mr. Langen's electric tramway there. The Berliner Elektricitäts-Gesellschaft has formulated a scheme for the erection of an electrical station at Harburg for working an electric tramway, as well as for the supply of current for lighting and motors. The Elektricitäts-Gesellschaft "Union," of Berlin, have been negotiating with the Elbing Municipality to build an electric tramway in that town.

Telephony at the Law Courts.—It is stated that by permission of Lord Chief Justice Russell an interesting experiment in telephony is being made at the Royal Courts of Justice in the Strand. This is the adoption of the system which has been tried in theatres and in churches, by which

Digitized by Google

the subscribers to a telephone exchange are able to hear what is going on in the particular room with which the telephone wire is connected. The experiment is being made in the court of the Lord Chief Justice, where advantage is being taken of the recess to fit a receiver close to the bench, a second at the desk of the clerk of the court, or associate, as he is called there, and a third at the counsels' bench. The idea is that solicitors and others who are interested in any case may, by having their telephones connected with the court of the Lord Chief Justice, listen in their own offices or residences to the legal arguments which are advanced on the one side or the other, as well as the decision of the judge. If successful, the system will be introduced into the other courts.

Transmission of Power in Italy.—An installation of the electrical transmission of power from Pale to Foligno is now being carried out, this being the first plant of its kind in Italy where polyphase currents will be used. The power will be obtained from the Menatre, in the proximity of Pale, and the water will be conveyed to the turbines at the generating station in Pale by means of a canal and conduits. There will be installed three turbines, each of 100 h.p., and each coupled direct from its horizontal shaft to a polyphase generator giving current at 2,000 volts. The length of the primary conductors, which are divided into two circuits, is 4·34 miles. One of these circuits will energise transformers for the supply of current for lighting purposes, and the other for motive power. The distributing station is situated in the centre of Foligno. From here the high-pressure current will pass to nine transformer stations, where the current will be distributed to consumers. The electrical plant emanates from the Oerlikon Maschinenfabrik, and the turbines from the Società Italo-Svizzera, of Bologna.

An Electrical Accident.—Last Sunday afternoon two employés of the Brush Company were repairing one of the switch pillars which stand about 20ft. apart along the switch gallery of the station of the City of London Electric Lighting Company, Limited, at Bankside. One of the men, a fitter, was at work behind the pillar, about 5ft. from the gallery floor, having used a ladder for getting up. His labourer, a man named Hearne, took the ladder away unnoticed, placed it against an adjacent pillar which was "alive" at the time, and went up to the top, where the only exposed contacts are. The first intimation that anything was wrong was conveyed by a scream from the injured man, and on the fitter coming round to the front he saw his mate lying on the gallery. He jumped down, and with the assistance of the station hands, who were soon on the spot, tried to resuscitate the man, but their efforts were unavailing. A doctor arrived shortly after the accident, but he immediately pronounced life extinct. The deceased had been employed on work of the same kind for about two months, and knew thoroughly the danger of touching anything. Only 15ft. from where the accident occurred a notice was displayed absolutely forbidding anyone to do the very thing which led to the man's death. The pressure was 2,000 volts alternating. No burns or discolouration were noticed either on the skin or clothing of the man, but there was an ugly wound on the back of his head caused by the fall against the gallery railing.

Electric Lighting in France.—The company which has undertaken to light the streets of Gucret electrically has commenced to lay the mains; the work is to be completed by January 1. Action has been taken by the owner of the gasworks at Bar-le-Duc against the Municipality for having granted a concession for electric lighting to Mr. Goret. An agreement has been come to between the Biarritz Municipality and the local gas company by which the latter will supply the electric light to the town. Mr. Charton, of Charlieu (Loire), has proposed a scheme for the erection of a central electric light station, which is under the consideration of the authorities, but there is the difficulty in the way that the gas company hold a concession which does not expire until 1911. The electric light is making good headway at Dijon. The local company was formed in 1891, and the following year supplied 1,000 lamps. The figure has now gone up to 8,000 lamps. A central station has been opened at La Terrasse (Isère). Power is obtained from the Carre cascade. The plant has been furnished by Messrs. Alioth, of Basle. Longuyon (Meurthe-et-Moselle) has had the streets hitherto lighted by oil, but will now adopt the electric light. The work will be carried out by Mr. Charles Brézol, of Charleville. At St. Rambert (Ain) a central electric light station is to be established, power being obtained from the stream about a mile and a quarter distant, where about 120 h.p. is available. Seven tenders have been received for electric lighting the port and canal of Caen, and a special committee has been appointed to look into them. The railway station and town of Capdenac are to be lighted by electricity. A committee has been appointed by the Neauville Municipality to enquire into the subject of introducing the electric light. At Aix-les-Bains the local authorities are pressing the gas company for a speedy reply as to whether they are or are not prepared to supply the electric light. Various offers have been made to the Municipality, who desire to have the electric light. Offers have been made to Cosne-sur-l'Œil (Allier), a town of 2,000 inhabitants, for a double scheme of water and electric light supply.

The Waterloo-City Electric Railway. — The *Standard* has now discovered that an electric railway between the City and Waterloo is in course of construction. In the course of an article, it says: The new line has unbroken continuity of more than a mile and a half from the great terminus of the London and South-Western line—a length sufficient for the keenest competition with the omnibuses. Great relief to the street traffic will be afforded by an underground circular subway surrounding the great central underground station, with its booking offices, lifts, and passenger platforms. This will occupy all the space between the ends of Queen Victoria-street, the Poultry, Princes and Threadneedle streets, Cornhill, and Lombard-street. Further interest attaches to the new line of being the first to enter into the longest and most important underground central station of the busiest locality in the world. The circular subway will have its floor at 10ft. below the present surface, and will be itself 8ft. in height, there being 2ft. of roof above it. Access will be had to it by stairs at the angle corner of Queen Victoria-street and the Poultry; at the angle of the Union Bank with Princes-street; at the opposite corner of the Bank of England; in front of the Royal Exchange; at the angle of Cornhill with Lombard-street; at the side of the Mansion House in Walbrook; and at the angle of Walbrook with Queen Victoria-street. By it passengers can pass to or from any of those points without being exposed to the dangers of crossing the busy traffic, or the surface above ground. These stairs have been planned in the slackways which vehicular traffic always leaves near the corners of the streets, so that they will not interfere with the horse roads or the footways. At the Waterloo end the arrangements are planned with special regard to the convenience of passengers arriving or departing by the trains of the South-Western Company. The electric railway will enter at the arches on which the terminus is built, and at right angles to the whole of the numerous

Digitized by Google

arrival, departure, and suburban platforms, from each of which descent by stairs will give access to the platforms of the new railway. The work is being carried on under the joint engineering control of Mr. Galbraith, of the South-Western, and Mr. Greathead. The contract for the two parallel tunnels has been let, and the caissons which will form the means of access to the borings have already been sunk under the staging at Blackfriars Bridge to a depth of 50ft. As soon as the depth of the floors of the intended tunnels (65ft.) is attained, the four protecting shields and the mechanical excavators will be lowered into position, and the driving of the tunnels will be carried on simultaneously in both directions. The site of the generating station has not been fixed upon, but it will probably be at the Waterloo terminus. There will have to be reviewed the question of short trains and short intervals, or long trains and long intervals, although the nature of the traffic arriving by railway main-line trains and by suburban trains will be an essential factor in its determination on the Waterloo and City line.

Laying of New Mains.—The Highways Committee of the County Council reported on Tuesday they had during the recess sanctioned, subject to certain conditions, the laying of electric lighting mains by the Notting Hill Electric Lighting Company, the House-to-House Electric Light Supply Company, and the Woolwich District Electric Light Company. The County of London and Brush Provincial Electric Lighting Company gave various notices under the County of London (North) Electric Lighting Order, 1892. There is, however, one most important point connected with the system of supply proposed to be adopted by the company to which the committee directed special attention. The company proposes to lay high-tension mains from the generating station to transformer-chambers and thence by means of low-tension cables to the consumers. These transformer-chambers, of which under these notices more than 50 would be constructed, and each of which would according to the plan submitted by the company occupy a space of about 13ft. deep, 12ft. long, and 7½ft. wide, the company proposes to place under the surface in the public thoroughfares; and the committee are strongly of opinion that, as it is quite possible for the work of distribution to be carried on if the necessary accommodation were provided in premises adjoining, the Council should hesitate before acceding to the proposition that the public thoroughfares shall be used for the purpose. They have directed that the attention of the Board of Trade shall be called to this matter, with a view to its consideration in connection with the approval or otherwise of the company's system of supply. They accordingly recommended that the sanction of the Council be given to the laying of the mains, and the construction of the small drawing-in and junction boxes, but not the transformer-chambers; that the mains be laid under the footways wherever it is found practicable to do so; that the low-tension mains be placed 9in. below the underside of the paving, and those of high tension at least a foot lower; that no street boxes shall be constructed until full details shall have been submitted to and approved by the Council's chief engineer; that separate boxes be used for the high and low tension mains respectively; and that, as an additional precaution against accident through defective insulation of the mains, each of the high-tension street boxes be provided with an inner as well as an outer cover, the two insulated from each other as far as practicable, and that the outer cover be efficiently connected to earth; and that the Council do formally signify its disapproval of all the works referred to in the nine notices, other than the laying of the mains and the construction of the small drawing in and junction boxes, in the area shown upon the plan No. 198 submitted with the notices. Notices have also been received from the same company under the Wandsworth Electric Lighting Order, 1892, from the Kensington and Knightsbridge Electric Lighting Company, the Vestry of St. Pancras, the St. James's and Pall Mall Electric Light Company, the Charing Cross and Strand Electricity Supply Corporation, the Westminster Electric Supply Corporation, and the Vestry of Islington.

Feeder and Main Patent.—Judge Acheson, of the United States Circuit Court of Appeals in Philadelphia, has given a decision in the case of the Edison Electric Light Company against Westinghouse, Church, Kerr, and Co. The suit was brought for injunction and damages because of the alleged infringement of the Edison feeder and main patent. In the United States Circuit Court for New Jersey last March an interlocutory degree granting the injunction was granted by Judge Green. An appeal was taken to the Circuit Court of Appeals. Judge Acheson's decision is in favour of the defendant, and in his opinion the judge said: "This patent does not deal with the complicated general problem of the distribution of electricity and the subdivision of the current for the purpose of domestic illumination. The patent is not for an incandescent lamp or for a dynamo for generating electricity, or for the arrangement of the lamps in multiple arc, or for indicating and regulating devices for controlling the current from a central station, singly or combined. The patent deals with the one particular difficulty of drop in tension or fall in pressure—loss of E.M.F.—due to the resistance of the conductors to the electric flow. To remedy the evil effect therefrom, the patentee provides special conductors for the transmission of electricity extending from the generator to the main conductors, with which the lamps are connected and from which they are served. The patent is for a specific arrangement and proportioning of the two sets of conductors, which, together, constitute the complete circuit." After a long review of the controversy, the judge continued: "The plan of electric distribution covered by the claims in question is not 'the creative work of that inventive faculty which it was the purpose of the constitution and patent laws to encourage and reward.' To sustain these claims would be to sanction a monopoly in that which belongs to the public." In conclusion, the judge said: "The appellant maintains that, under the ruling of the Supreme Court in the case of Miller *v.* Eagle Manufacturing Company, the first, second, and third claims of the patent in suit are void, because of the grant of an earlier patent to Mr. Edisen . . . . which dealt with the evil of drop in tension, and provided a remedy by feeding conductors, having no lamps therein, connected with the mains of the consumption circuits arranged in sets concentrically around the central generating station, and so proportioned as to secure equal electrical pressure throughout the entire system. It is contended that the invention described and claimed in the earlier patent is for one form of the alleged invention described in the later patent and covered by the three first claims thereof, and that no one could use the invention of the earlier patent without infringing these later claims. The question thus raised is a serious one; but we do not deem it to be necessary to consider it, inasmuch as the views we have expressed upon the other branch of the case are decisive. The decree of the Court below is reversed and the cause is remanded, with directions to enter a decree dismissing the bill of complaint with costs."

Wonders of Science.—A scribe, writing under the initials of "J. H. R.," has been endeavouring to enlighten the readers of *Black and White* on the "wonders of

Digitized by Google

science—a forecast." The illustrations accompanying the article are not bad, but as they bear the artist's name under date of 1892, *Black and White* must have kept them in stock a long time. It is a pity that "J. H. R.,' before writing the forecast in question, did not make himself properly acquainted with what has been done in regard to electric fire-engines and submarine boats. The two leading makers of steam fire-engines have already constructed electric fire-engines, but they have wisely refrained from using storage batteries, simply mounting an electric motor on the engine to actuate the pumps, the current being obtained from a street main. But the idea of storage battery fire-engines seems to be wide of the mark. Even the one illustrated appears to travel so slowly that the boys running in front of it are taking it easy. As to submarine boats, possibly "J. H. R." has never heard of the French "Gymnote" and one or two other submarine electric boats experimentally tried by the French and Italian Governments. However, let "J. H. R." speak for himself: "In the department of electricity alone the question is, where are we going to stop? The lessons learnt from the City and South London electrical subterranean railway, which may be taken as a typical development, have been many and various. There are some half-dozen projects of the kind in view, and we may reasonably look forward to a complete metropolitan network of cheap and speedy subterranean railways—a consummation the contemplation of which would have positively shocked our grandfathers, who were so much astonished at the "Puffing Billy" of the not very remote past. Two of the accompanying illustrations deal with electric motors for the road and the sea. In the former is shown the storage battery at work on the useful 'bus, the fire-engine and the 'trike' all illuminated by the electric light. Although the other day Londoners had the opportunity of witnessing a vehicle propelled by such means running through Cheapside, not so much public attention has been paid to electrical road traffic as the subject deserves. It is true that, as regards surface rail and tramways, marked advances have been made, notably in the North of Ireland and at Walsall, to go no further than these islands. It is always easier, however, to obtain encouragement (and capital) for a big enterprise which appeals to the imagination than to secure support for a purely industrial undertaking, even though the latter may promise to revolutionise our everyday doings. But considering what we know and have done already, it is not at all unreasonable to assume that the horse will be superseded for rapid traffic in our cities, while the electrical tricycle suggests wonderful possibilities. With regard to sub-aqueous enterprise, the limit at present is found in the submarine engine of war, which is looked upon for various reasons as little more than a dangerous toy. But what possibilities have we not here? It may be supposed that no one would be found to argue that a passenger service of the kind illustrated could not be conducted across the Channel. The main question to be considered is not one of possibility from the point of view of the boat, but whether it is worth while financially to engage in such an undertaking, coupled with the necessary consideration whether the Channel on account of depth and traffic is fit for it."

Indo-European Telegraph Tariff.—The Chamber of Commerce at Madras has addressed the following letter to the Government of India: "The Chamber has from time to time pressed upon Government the necessity felt for a reduction of the telegraph tariff between India and Europe. A lecture delivered recently before the Society of Arts by Mr. E. O. Walker, C.I.E., late of the Telegraph Department, has again drawn the attention of the Chamber to the matter, and in view of the approaching international telegraph conference, which will assemble in 1896, I am desired to solicit that the Government of India, in furtherance of the object, will use its influence to secure instructions being given to the Indian delegate who will attend the conference to press for a reduction. Setting aside the probability of an increase of traffic following upon a reduction in charge, which has generally been the case, it is thought that the profits made upon foreign telegrams at present are sufficiently large to admit of at least a tentative reduction. For Indo-European messages the share of the Indian Government amounts to something like Rs. 6,00,000 per annum. In addition, the tolls in transit of messages to and from the Far East bring in a rather larger amount. These earnings must amply meet the interest on capital outlay on the circuits, the cost of maintenance, and the wages of the staff employed to deal with foreign telegrams in India, as well as the expense of check, account, and audit; and it is in this view that the Chamber feels that there is a strong case for the consideration of Government. The Telegraph Department may naturally wish to show good results by massing inland and foreign message revenue, charges for railway telegraphs, and receipts from other sources; but the Chamber respectfully submits that when returns begin to exceed the expenses in any particular direction, the branch of the community which contributes to those returns should receive some remission of charges. It is believed that this aspect of the case will commend itself to Government. As regards the financial result to the Telegraph Department, the Chamber believes that if the tariff were lowered yearly by eight annas per word to Rs. 2, or even less, there would be no loss. This opinion is strengthened by the fact that it has been possible to reduce, since May 1, 1891, the rate between England and the Australian colonies (Queensland excepted) by nearly one-half, and the additional traffic attracted by a lower charge has at the present time compensated for the estimated loss of revenue. At first it would appear that a sacrifice was made, but this occurred, doubtless, from too large a reduction in tariff (one-half) being effected at one time. The Chamber advocates a gradually descending scale. Again, when the minimum chargeable unit for telegrams with Europe was reduced on January 1, 1876, from ten words to one word, in the year following, although the average value of such messages decreased 12 per cent., private senders despatched 22·44 per cent. more messages, and the gross value of the traffic increased by 5·34 per cent. In the year following that again the number of messages increased by 38·14 per cent., and the gross value 27·28 per cent. To take another instance which illustrates the contention of the Chamber. Up to January 1, 1882, a telegram in India cost a minimum of one rupee. On that date the 'deferred' class was introduced. In the year 1881-82 private messages in India numbered 1,035,137, and were valued at Rs. 13,16,851. In the year following (when the eight-anna telegram was sanctioned) there were 1,539,975 telegrams, valued at Rs. 26,18,298. Some years ago, the Chamber is aware, the Indian Government had to consider, in connection with foreign tariff, the loss accruing from the Persian lines and cables—that is, of the Indo-European Telegraph Department—but that loss has now disappeared. As regards the Eastern Telegraph Company and the Indo-European Telegraph Company, the dividends now being paid are so good, and their reserve funds laid by out of earnings so large (over £600,000), that the Chamber thinks that these companies may with propriety be asked to share the risk of a reduced tariff."

EALING ELECTRIC LIGHTING.

The installation described in our last issue was formally opened on Wednesday last by Mr. E. M. Nelson, J.P., chairman of the Local Board, in the presence of a goodly assemblage of invited guests. As we have already described the work, we have only briefly to refer to the proceedings of the evening. Punctually at 6.45 the guests assembled in the dynamo-room, and after a few introductory words from Mr. Graham Harris (Messrs. Bramwell and Harris) the chairman switched on the current, and the energising of the pilot arc was greeted with cheers. We were unable in our last issue to illustrate the switchboard provided by Messrs. Siemens, but that lapse is now remedied, and the accompanying drawing will enable the reader to understand the arrangement. There are two main switchboards—one for public and the other for private lighting. The connections on the board for private lighting allow of either or all of the four alternators being connected either singly or in parallel to any one or all of the four feeder mains, or of either or both exciters being connected to either or all the alternators. The switchboard for public lighting is similar to the alternator board, and is so arranged that any one of the three direct-current machines can be connected to either one of the two circuits upon which the arc lamps are placed. After switching on the current the company left in brakes for the Public Buildings, in the hall of which, as our readers know, an electric exhibition has been arranged. Here Mr. Nelson dwelt briefly upon the history of the electric light movement in Ealing, and insisted that the work was good, and that the day was a most auspicious one in the annals of the district. While speaking, the lamps at the various stands had been switched on, and the declaration "that this exhibition is now open" was greeted with cheers and the martial sound of the trumpet. Subsequently the band discoursed sweet music, while the invited guests made still another move to the Lyric Hall, wherein they were entertained to dinner by the authorities. The dinner was well served, and the after-dinner speeches commendable for their brevity. After the toast of "The Queen," Mr. C. Jones gave "The Town and Industries of Ealing." He described his career at Ealing, coming

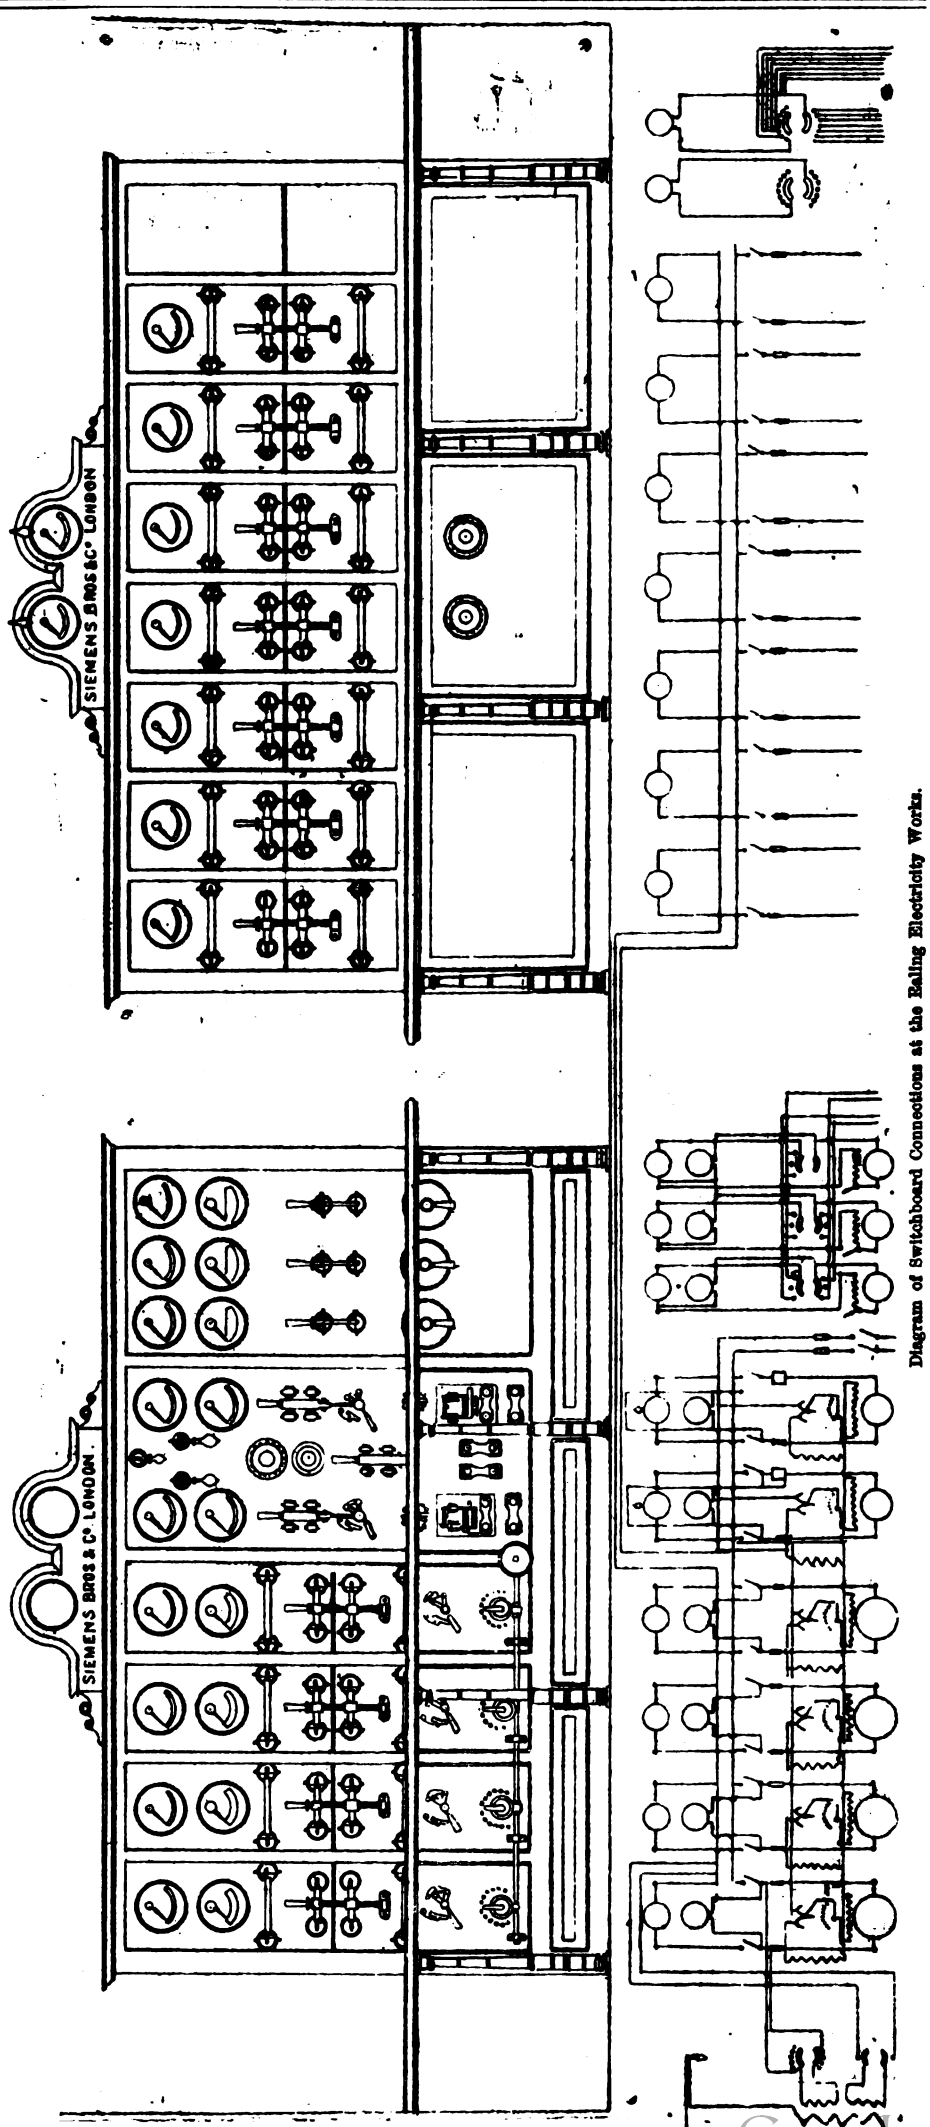

Diagram of Switchboard Connections at the Ealing Electricity Works.

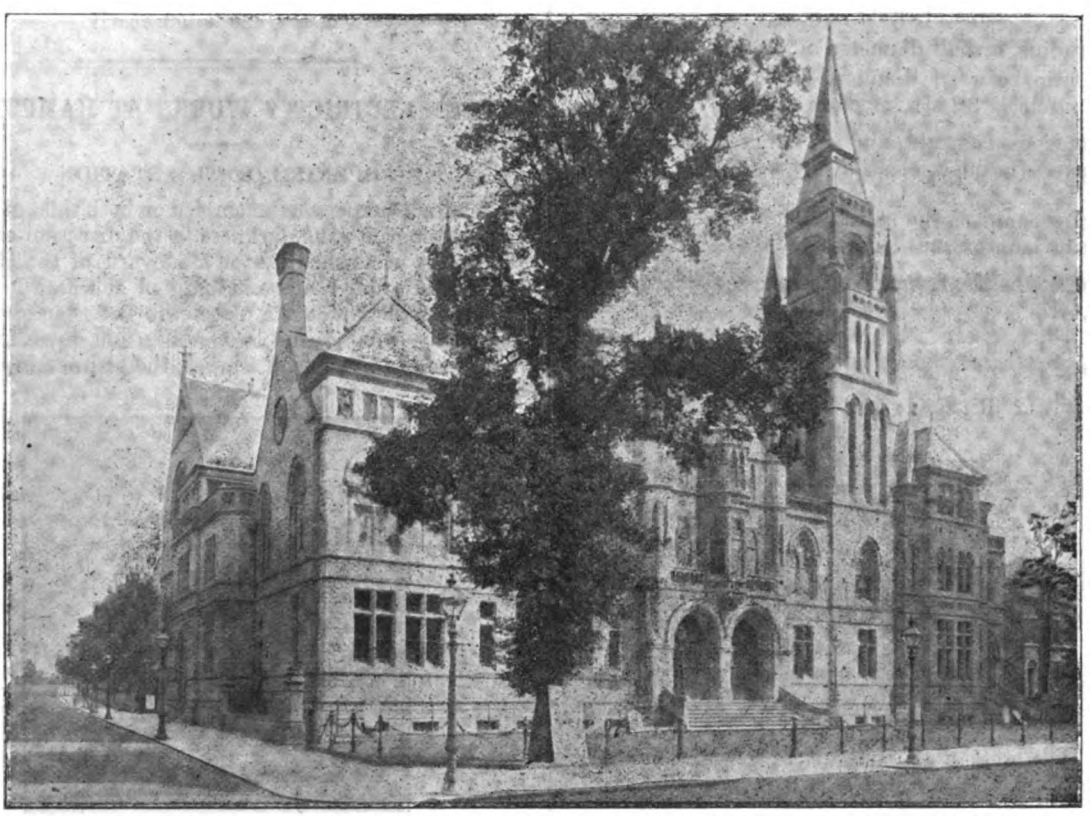
there when it was a mere village, making in those early years a rate upon £17,000 ratable value, watching and participating in its growth till its ratable value had arrived at something like £175,000. He looked upon Ealing as one of the most progressive and best-managed towns in suburban London. It was perfectly evident his hearers thought so likewise, as did the business men who responded to the toast. The chairman had the next toast, and gave "The Engineers" (Messrs. Bramwell and Harris), describing how under great difficulties they had kept their word in being ready to open that night. Sir Frederick Bramwell, in a few happy phrases, declined the credit of the work, throwing that upon the shoulders of Mr. Graham Harris. The latter, in his reply, gave Sir Frederick a Roland for his Oliver, acknowledging the difficulties and crediting the success of overcoming those difficulties to the contractors, whose healths he toasted, and to which toast Mr. A. Siemens and Mr. T. Callender replied. "The Visitors" and "The Chairman" concluded the



Ealing Public Buildings

business of a pleasant evening, and we will simply re-echo the words of various speakers and wish success to the Ealing installation.

CITY AND GUILDS OF LONDON INSTITUTE.

LECTURE IV.—FORMULÆ AND EXAMPLES CONNECTED WITH OHM'S LAW.

(Specially contributed.)

Having Ohm's law, it is easy to tell the voltage required to produce any required current in a wire of given resistance.

Example 1.—Given a wire of two ohms resistance, what voltage is required to obtain a current of 18 amperes?

$$C = \frac{E}{R};$$

putting the given values in the equation, we have

$$18 = \frac{E}{2},$$

or,
$$18 \times 2 = E,$$
$$36 = E:$$

that is, we require 36 volts.

Example 2.—Suppose we have a resistance of $\frac{1}{4}$ ohm, and require a current of 200 amperes. What voltage must we have?

Again putting the given values in the equation,

$$200 = \frac{E}{\frac{1}{4}};$$

or,
$$200 \times \tfrac{1}{4} = E;$$
$$50 = E;$$

that is, we require 50 volts.

Calculations, however, are not usually so simple as this in practice; and unless you can apply your knowledge to practical work, it is of little service to you. Let us first turn our attention to the resistances that go to make up a circuit, and for the moment trouble only about the external circuit. Usually, the conductor in the circuit consists of copper wire of circular section. The formulæ, however, which we obtain will serve for any conductor of circular section.

I have here a piece of wire. Call its length L. Taking another piece of wire of exactly the same section, and connecting it to the first, we have now a length of conductor = L + L, or, = 2 L.

L L

When conductors are added one after the other like that, they are said to be in *series*, or we may speak of them as resistances in series.

Let us symbolise resistance by R. Then if

R represent the resistance of a wire of given length, material, and sectional area,

2 R will represent the resistance of double that length, the materials and sectional area remaining the same.

Thus, the total resistance of any number of resistances in series is the sum of the separate resistances.

If, then, we have four separate resistances in series, having respectively 4, 5, 6, and 7 ohms resistance, the total resistance is 4 + 5 + 6 + 7 = 22 ohms.

Now, if we take any conductor like this copper wire we can at will alter its length or its sectional area, or both, or we can alter the material of the conductor. Whatever change we make, whether of length, sectional area, or material, has its independent effect upon the resistance of the circuit.

Digitized by Google

We have seen that the resistance of any particular wire increases directly as its length; let us now consider the effect of sectional area.

Here are two wires of the same material, length, and section, and I find that by putting these two wires side by side

$$\frac{R}{R}$$

or, as we say, in parallel, the resistance R is not 2 R nor R, but $\frac{R}{2}$.

Doubling the sectional area, then, has halved the resistance, but if I have doubled the sectional area I have doubled the weight, W. Thus, resistance with length and material kept the same varies inversely as the sectional area or the weight.

When the sectional area is circular in form—as it usually is when wire is used—its area is represented thus:

$$\text{area of circle} = r^2 \pi;$$

where r = radius, or half diameter of circle;

π = ratio between diameter and circumference of circle = 3·1416, or more roughly $\frac{22}{7}$.

The value of π is constant, and so the area of any circle must vary as r^2 (radius^2), or as d^2, where d represents the diameter.

We can now compare the resistances of two wires, when we know their lengths and diameters.

Let R and R_1 be the respective resistances;
L „ L_1 „ „ lengths;
d „ d_1 „ „ diameters;
S „ S_1 „ „ sectional areas;

then $$R : R_1 :: \frac{L}{d^2} : \frac{L_1}{d_1^2};$$

$$\frac{R}{R_1} = \frac{\frac{L}{d^2}}{\frac{L_1}{d_1^2}} = \frac{L\,d_1^2}{L_1\,d^2}$$

If sectional area is known this formula is written,

$$\frac{R}{R_1} = \frac{L\,S_1}{L_1\,S}.$$

Fortunately, in practice most of the common calculations are tabulated so that it is only necessary to consult the tables, but it is better that you should thoroughly familiarise yourselves with methods of calculation, rather than rely only on tables which when wanted may not be at hand.

Example 3.—Two wires of the same length and material are found to have resistances of 4 ohms and 11 ohms respectively. If the area of the first is ·0064 square inch, what is the area of the second?

Here length is the same, so we need not trouble about it in the formula, but use

$$\frac{R}{R_1} = \frac{S_1}{S}.$$

Putting in the formula the known values, we get

$$\frac{4}{11} = \frac{S_1}{\cdot 0064},$$

or,
$$\frac{4 \times \cdot 0064}{11} = S_1$$

$$= \frac{\cdot 0256}{11} = S_1$$

$$= \cdot 0023 = S_1,$$

that is, the sectional area of the second wire is ·0023 square inch.

Taking Glover's tables, we find the resistance of 1,000 yards of $^7/_{20\cdot5}$ S.W.G. wire at 60deg. F. given as 4·0864 ohms, and same length, etc., of $^7/_{25}$ as 11·124 ohms, while area of former is given as ·0064 square inch, and of latter as ·0022. In the above question the resistances are not taken exactly the same as in the tables, but sufficiently near to see that the result is correct. If required, we can get the diameter of the wires from the area, for area = $r^2 \pi$, as before stated.

Example 4.—What must be the diameter of a wire 500ft. long that has three times the resistance of a wire 150ft. long, and having a diameter of ·5in.

We know $$\frac{R}{R_1} = \frac{L\,d_1^2}{L_1\,d^2}.$$

In this case $R_1 = 3\,R$. So that we may write

$$\frac{1}{3} = \frac{L\,d_1^2}{L_1\,d^2};$$

$$= \frac{150 \cdot d_1^2}{500 \times \cdot 25} = \frac{150 \cdot d_1^2}{125} = \frac{6 \cdot d_1^2}{5};$$

$$\frac{1}{3} \times \frac{5}{6} = d_1^2;$$

$$\frac{5}{18} = d_1^2;$$

$$d_1^2 = \cdot 28 \text{ nearly};$$

$$d_1 = \sqrt{\cdot 28} = \cdot 53 \text{ nearly}.$$

THE ELECTRICITY WORKS AT HAMPSTEAD.

OPENING OF THE STATION.

A few knots of persons assembled on both sides of Finchley-road, peering into the darkness in the direction of that end of Lithos-road formed by the stoneyard of the Hampstead Vestry, indicated that something of the weird and mysterious was about to take place. It was then about 7 p.m. on Monday evening, the 1st October, and down Lithos-road were passing in twos and threes the visitors invited to be

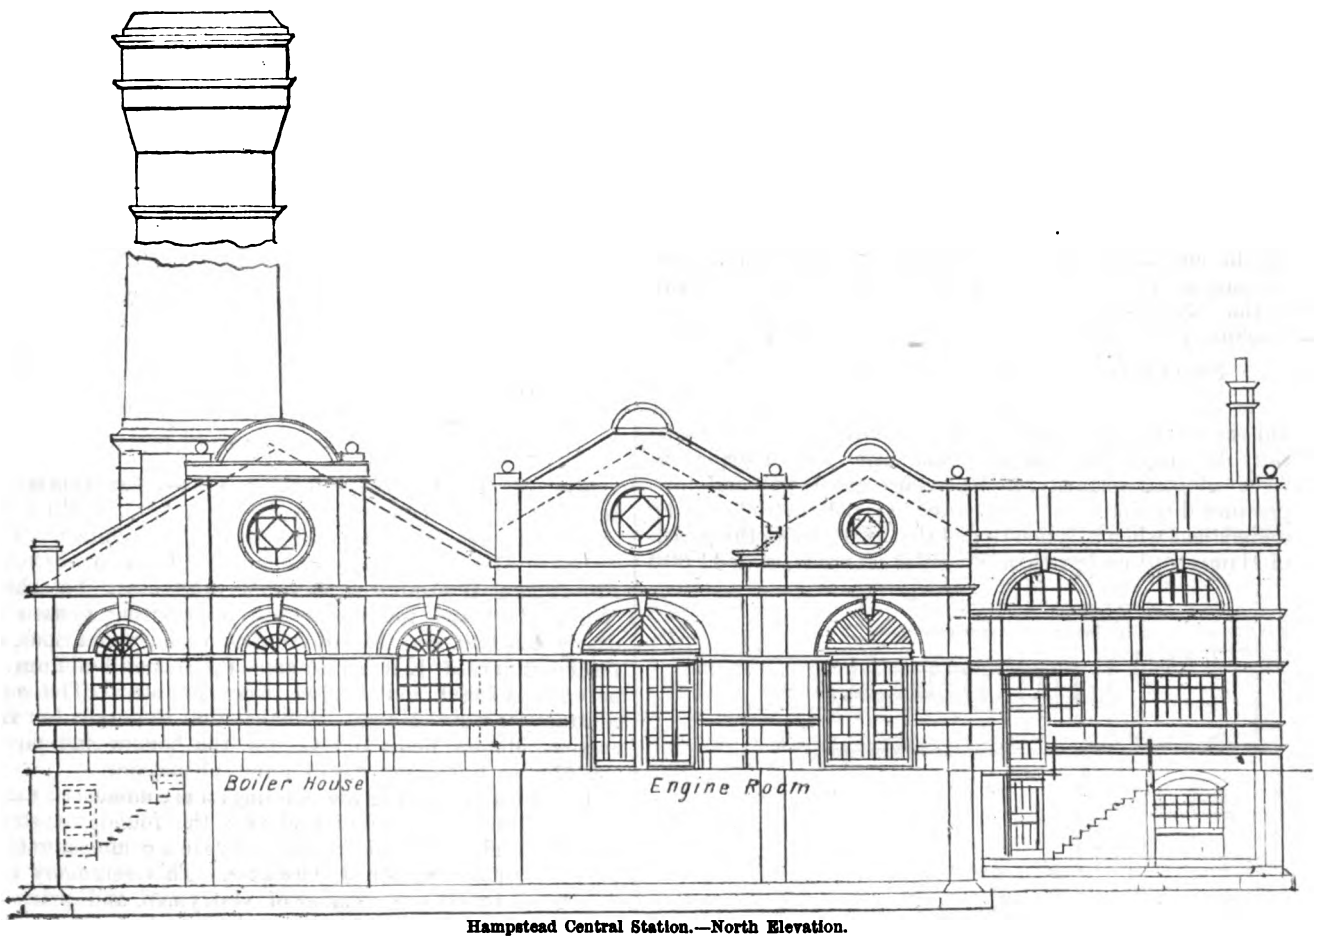
MR. R. A. CHATTOCK.

present at the inauguration of the electricity works of the Hampstead Vestry. Dim oil lamps placed at intervals on the ground guided the footsteps of the guests through the stoneyard, which, it may be mentioned, was established in 1879. This yard, which covers an area of two acres, is the depôt for the carts and implements and materials used by the Vestry, whilst in the winter the unemployed are there provided with a certain amount of work. Reaching the end of the yard, where the electricity works have been built, the visitors entered the station through the outer office. But where was the electric light?

At first sight the engine and dynamo room appeared to be in absolute darkness, but after a little time a few oil lamps arranged round the room became visible. These lamps served their purpose; they were barely sufficient to allow one to grope about the room, but just ample to let the visitors collide with one another, and that, too, with an inward, if not verbally expressed, exchange of compliments. The weird scene was rendered more impressive by the hum of one of the combinations—one of the arc lighters, in fact,

Digitized by Google

A little surprise at this state of affairs was manifested by some of the visitors, but the reason was eventually fully explained. Searches after friends led to little result beyond perhaps a few collisions, but until that evening we were not aware that the science of football was so well understood by the Hampsteadonians. Then, again, one or



Hampstead Central Station.—North Elevation.

two gentlemen endeavoured to make the acquaintance of a Siemens high-pressure arc light machine, but the dynamo refused to be coaxed, shrinking in its shell behind the roping. Now, who would think of making friends with a stranger in the dark, and in this manner, too, especially when the stranger carries on his nose, painted

Hampstead Central Station.—Longitudinal Section.

in large letters, the word "danger." No one, of course; but danger is a thing which is laughed at, and quite right—when the danger is far away. We do not know whether it is true that two new watchmakers' shops have been opened at Hampstead since Monday. If so, that explains why so many gentlemen played in the same field as the alternators on that occasion. After a little trouble, thanks to his photograph which we reproduce, we managed to discover Mr. R. A. Chattock, the electrical engineer to the Vestry.

A nice little joke at the expense of oil was perpetrated. As already stated, the reason for the oil lamp illumination of the station was forthcoming. Mr. J. Thwaites, A.I.E.E., the chairman of the Electric Lighting Committee of the Vestry, committed it. The oil lamps were dim; possibly the rats infesting the district had removed most of the oil, or perhaps the wicks had not been trimmed. Anyhow, it is many years since we saw such ill effects from lighting by means of oil lamps, bad as they are. It was to show, as Mr. Thwaites put it, the great contrast between the old light and the new, the latter being, of course, the electric light, which was subsequently switched on. This striking comparison, it is scarcely necessary to say, hugely tickled the humouristic propensities of those present.

Mr. W. H. PREECE, in the course of some well-chosen remarks, stated that 1,400 incandescent lamps were con

Digitized by Google

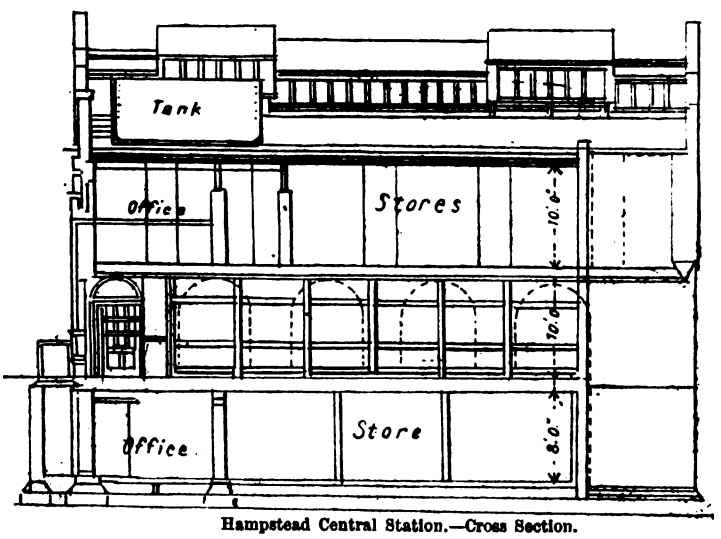
nected to the mains, and that in a week or two this number would be increased to 3,000 lamps, apart, of course, from public lighting. With a view to emphasise his frequently expressed opinion that the electric light is the poor man's light, the speaker said that from an analysis of 24 electric light stations he had found that the average cost of each incandescent electric lamp was 9s. a year, and that it consumed between 17 and 18 units. The figure of 9s. was, he observed, also the average price per annum for a gas light in the case of 24 gas undertakings.

Mr. FLETCHER, having made a few observations, proposed a vote of thanks to Messrs. Siemens Bros. and Co., Limited, the contractors. To this Mr. ALEX. SIEMENS suitably responded.

Amid cheers, Mr. R. Hackworth then switched on the incandescent lamps in the station, and Mr. Thwaites turned on the current to the arc lamps in Finchley-road. The visitors, at the invitation of Mr. A. Siemens, next drank to the "Success of the Electric Light," after which the machinery was inspected and explained by the engineers.

PRELIMINARY STEPS IN ELECTRIC LIGHTING.

As in the case of Ealing, so in regard to Hampstead did the district comprised in the provisional order practically determine the system of production and distribution to be adopted—namely, high-pressure generation and low-pressure distribution. The extent of the district will be understood when it is mentioned that there are in the parish of Hampstead no less than 53 miles of roads, with 11,000



Hampstead Central Station.—Cross Section.

occupied houses, and that there is every prospect of a rapid appropriation by builders of the 400 acres of land which alone remain to fall into their hands. The ratepayers by a free use of the light will help to reduce the public expense, and residents have the satisfaction of knowing that in paying for the electric lighting of their houses they are not helping to fill the pockets of shareholders, but are directing their money into a channel which will assist either in reducing the rates or enable the Vestry to bestow further benefits upon the parish.

The parish of Hampstead has had its vicissitudes in connection with electric lighting. When the matter was first considered several years ago, a committee was appointed to deal with it, but their recommendation that the Vestry should provide a municipal supply was shelved. Mr. F. E. Baines, C.B., who was the first chairman of this committee, was succeeded in 1891 by Mr. James Thwaites, who has taken an active part in bringing the project to a successful issue. Some time after the rejection of the proposal to establish a municipal supply, the Vestry very wisely reconsidered the subject, and as a result the services of Mr. W. H. Preece were called in to advise the Vestry. The report prepared by Mr. Preece having been fully discussed, the Vestry decided to apply for a provisional order, which was granted. In December, 1892, the Vestry resolved, rather than to transfer their powers to a company, to undertake the work of supplying the parish with the electric light, and in due course they applied to the London County Council for permission to borrow the sum of £30,000 upon the security of the lighting rates of the parish. Mr. Preece was instructed to prepare the plans and specifications, and the works have been carried out in accordance with his scheme, and under the supervision of the Electric Lighting Committee.

It will be seen from the list given below that the members of the Electric Lighting Committee are numerous:

J. THWAITES, A.I.E.E.,	HACKWORTH, R.
AITCHISON, T. [chairman.	HALL, C.
BARTLETT, C. T.	HARBEN, H.
BECKETT, H.	HANHART, N.
BENCE, H. R.	HARDCASTLE, J.
BODEN, J. W.	JONES, W. J.
BUCKINGHAM, J. S.	KING, C. B.
BUSTON, S. W.	LEFFMANN, P.
COLLEY, J.	PADBURY, R. H.
CUFF, W. S.	PAYNE, E. S.
DALNTON, S. J.	RANDALL, T. G.
DIMOND, W.	REED, C. H.
DOBBS, S.	RUSSELL, C. A.
EDWARDS, F. YEATS.	RYALLS, C. W.
ELLIOTT, E.	SHAW, P. G. C.
EVANS, M. H.	SMITH, T. EUSTACE.
FARMER, L.	SWAN, E.
FAULKNER, A.	UNDERWOOD, R.
FRAMPTON, W.	WELLS, T. N.
GRAHAM, H. HOWGRAVE.	WILLS, C. A.
GREENHILL, G.	YOUNG, R., Major-General.

Mr. W. H. Preece, F.R.S., has acted as consulting engineer to the Vestry, and Mr. A. Ardron, F.R.I.B.A., of 39, Victoria-street, Westminster, is the architect. The tender of Messrs. Siemens Bros. and Co., Limited, of Queen Anne's-gate, Westminster, to supply and erect the whole of the plant and the feeder and distributing system at nearly £20,000, and that of Messrs. Yerbury and Sons, of Birchington-road, Kilburn, to erect the station buildings at between £7,000 and £8,000, were accepted. The sub-contractors were Messrs. Willans and Robinson for the engines, Messrs. Bellis and Co. for the boilers and pipes, and Messrs. Lucas and Aird for the sub-stations.

The work of erecting the buildings was commenced early in 1893; in the autumn of that year the foundation-stone was laid, and in May of the present year a commemoration tablet was fixed by Mr. J. Thwaites. This ceremony was witnessed by a large number of vestrymen, and prior to the ceremony the company were photographed. The tablet is a large one, and bears the names of the principal gentlemen concerned. The ceremony was followed by a dinner at the Midland Hotel, St. Pancras. The toast of "The Vestry of Hampstead" was proposed by Mr. J. S. Fletcher, J.P., L.C.C., who congratulated that body upon its present work in giving the advantages of the electric light, and hoped it would be a financial success. Mr. Preece on the same occasion observed that the electric light would be the poor man's light, and that it was going to be successful financially.

The compulsory area of supply specified in the provisional order includes Arkwright-road, College-crescent, College-terrace, Finchley-road (from Arkwright-road to Swiss Cottage), Fitzjohn's-avenue, Frognal (from Finchley-road to Arkwright-road), Lithos-road, Maresfield-gardens, Netherhall-gardens, and Nutley-terrace. It appears, however, that the Vestry have a competitor in the Hampstead Electric Battery Company, who have for some time been furnishing a supply of the electric light to private consumers. The works of the company are situated close to those of the Vestry, the former being in Finchley-road, close to Lithos-road. The company, we are informed, have entered into agreements with their customers for periods ranging from 12 to 18 months, so that they intend to retain their clients. The sphere of operations by the company being restricted, the competition between them and the Vestry, who have a wide area of supply, should only be of a mild and friendly nature.

THE STATION BUILDINGS.

The details of the electricity works are shown in the accompanying illustrations, including plan, elevation, and section of the buildings, and views of the boilers and engines and dynamos. The buildings comprise a substantial structure erected in stock bricks, with red-brick dressing, having in the rear a chimney shaft 130ft. high. Ample room for future extensions of the buildings and of the plant is pro-

Digitized by Google

vided from the boiler-house end. As will be seen from the illustrations, the buildings consist of an engine-room built in two spans, one of 26ft. and the other of 16ft. The dimensions of the engine-room are 58ft. long, 42ft. wide, and 23ft. high. It is large enough to accommodate an increase in the incandescent and arc lighting machinery to the extent of 50 per cent. The boiler-house, which is at a lower level than the engine-room, is covered by one roof having a span of 43ft. It is 58ft. long and 24ft. 6in. high; its floor is 9ft. below that of the engine-room, which is on the ground level. It will be noticed that this arrangement allows of coal bunkers being provided under the roadway, these bunkers having a capacity of 100 tons of coal. The chimney is 8ft. in internal diameter, and up to a height of 50ft. it is divided into two compartments only, one of which is used with the present boiler plant, the other half being provided for future extensions. Offices, consisting of engineer's office, clerks' office, stores and testing room, are also provided. The water-tank for the supply of the boilers is fixed on the roof; it has a capacity of 10,000 gallons. Both the boiler-house and the engine and dynamo room are lighted by incandescent lamps, the latter having, in addition, two arc lamps for use as occasion may arise.

The Boiler-house.

The boiler-house, of which a photograph showing the line of boilers and mechanical stokers is annexed, contains four boilers of the Lancashire type, made by the Oldham Boiler Company, and supplied under a sub-contract, together with the steam-pipes, by Messrs. G. E. Belliss and Co., Limited, of Birmingham. Each boiler is 28ft. long and 8ft. in diameter, and will evaporate 5,000lb. of water an hour at a pressure of 150lb. The boilers are of Siemens-Martin steel, and each has been tested to a pressure of 250lb. They are provided with dead-weight safety-valves and Hopkinson's fittings throughout, including two safety-valves, and duplicate feed-water check-valves. The boilers are equipped with mechanical stokers, conveyor, and elevator of the type made by Messrs. Bennis and Co., of Bolton. The fuel is supplied to the stokers by a coal elevator, consisting of an endless chain and buckets working in a sheet-steel case, and a conveyor, consisting of a worm working in a trough from which the coal falls through shoots into the stoker hoppers. The coal, which is Welsh smokeless fuel, is shovelled into the buckets from the coal bunkers by the trimmers. The stoking machinery is driven by a small vertical engine, of which a duplicate is provided as reserve; and the whole is arranged with clutches, loose pulleys, and striking gear so as to be completely under control, and so that the breakdown of any portion of the machinery cannot interfere with the working of the station.

A complete duplicate service of feed water is arranged for each boiler—a supply being obtained from the mains of the water company and also from the before-mentioned storage tank. There are two Worthington feed pumps, each of which is capable of delivering 4,000 gallons of water per hour, and each can supply water to any or all of the boilers independently of the other. The feed water is heated by an exhaust steam-heater of the Babcock and Wilcox type, and also by a Green's economiser of 192 pipes placed in the main flue. Each heater is provided with a by-pass, and each can be used together with or independently of the other. The economiser, made by Messrs. E. Green and Son, Limited, of 2, Exchange-street, Manchester, has been constructed on their improved principle—namely, in two groups—thus allowing a space between to facilitate passage between the pipes in case of repairs or cleaning operations. These groups of pipes are coupled together at the top and bottom by expansion elbows, and the whole apparatus is fitted with patent access pipes at bottom, which provides an easy means of cleaning the deposit out of the bottom boxes without removing the branch pipes absolutely and breaking the whole of the joints. Being constructed to work at high pressure—150lb.—the apparatus is specially strengthened throughout, and fitted with patent internal lids to top boxes, which allows of greater water space therein.

The steam from the boilers is taken to the engines in a wrought-iron ring main, divided by valves placed between each engine and each boiler into sections, each section being drained. A small auxiliary steam ring connected to two sections of the main steam ring supplies steam to the feed-water pumps and stoker engines. The exhaust steam is carried through a cast-iron exhaust-pipe to the atmosphere 50ft. above the ground level.

The Engine and Dynamo Room.

The main steam-piping from the boilers forms a complete ring main in the engine and dynamo room, having connections to each boiler and engine, each connection being fitted with a stop valve. The steam-main is of wrought iron, with solid copper ring joints. Valves are provided in the main steam-pipe, so that the breakdown of any portion will not interfere with the working of more than one engine and one boiler at the same time.

The plant, which is divided into two parts—one for public and the other for private lighting—consists for the latter of one 200-kilowatt steam alternator, capable of supplying 5,700 8-c.p. lamps; two 100-kilowatt steam alternators, each of a capacity of 2,850 8-c.p. lamps; and one 20-kilowatt steam alternator for the supply of 570 8-c.p. lamps. For public arc lighting there are two 13-kilowatt steam dynamos, supplying 22 2,000-c.p. arcs. Two 18-kilowatt steam dynamos are provided for exciting the alternators, and for station lighting. The engines are of the Willans compound and the dynamos of the Siemens type, and are in all cases direct coupled.

The alternators have revolving disc armatures, the periodicity being 90. The large alternator of 200 kilowatts, which is coupled direct to a Willans compound engine, single acting, of 290 b.h.p., gives at 340 revolutions a current of 96 amperes at 2,100 volts. The two 100-kilowatt machines, at 385 revolutions, yield 48 amperes at 2,100 volts, and the 20-kilowatt alternator gives 9·5 amperes at the same pressure.

The two exciters, at 450 revolutions, each give 150 amperes at 100 volts, these being coupled direct to Willans E E type of engines. The exciters have bar armatures.

The two arc light machines, driven at 360 revolutions, are continuous-current generators, each giving 10 amperes at 1,300 volts, and capable of supplying 25 arc lamps in series. Each machine is direct coupled to a Willans D D engine.

The current from these dynamos is led to the station switchboard, which is arranged in a recess on one side of the room. This board, which is somewhat similar to that illustrated on another page in connection with the Ealing electricity works, is built up of polished slate panels, one panel being provided for each dynamo and one for each circuit. The alternators are connected through these panels by omnibus bars to the circuits, and they are arranged to work in parallel, a synchronising panel being provided for this purpose. Each panel is provided with an ammeter and voltmeter, fuses, etc., and the whole of the switchboard is mounted in a polished teak frame, and is railed off from the engine-room.

The engine-room is equipped with an overhead travelling crane of 10 tons capacity. It has a span of 25ft., and was constructed by Messrs. Appleby Bros., 22, Walbrook, E.C. The traveller differs in some respects from the cranes they have made for other dynamo-houses. The hauling ropes or chains respectively for lifting, traversing, and travelling are usually carried on the crab; but some inconvenience having been caused by these ropes fouling machinery, etc., they are worked from the gangway, which in this case runs along one side of the house. The crab has single and double purchase lifting gear and all appliances for travelling longitudinally, and for traversing from end to end of the main beams. These, and the end cradles which carry the travelling wheels, are of steel, and a steel rail for the cross traverse is riveted to the upper table of each main girder. The chain is of Best Best tested quality, and the proportions throughout give a factor of safety of not less than 5. The maximum load is quite easily lifted by two men, but one man works all motions with the ordinary loads. The details are neatly worked out, and attention has been given to several points which are sometimes overlooked, such as provision for lifting close to the wall, etc.

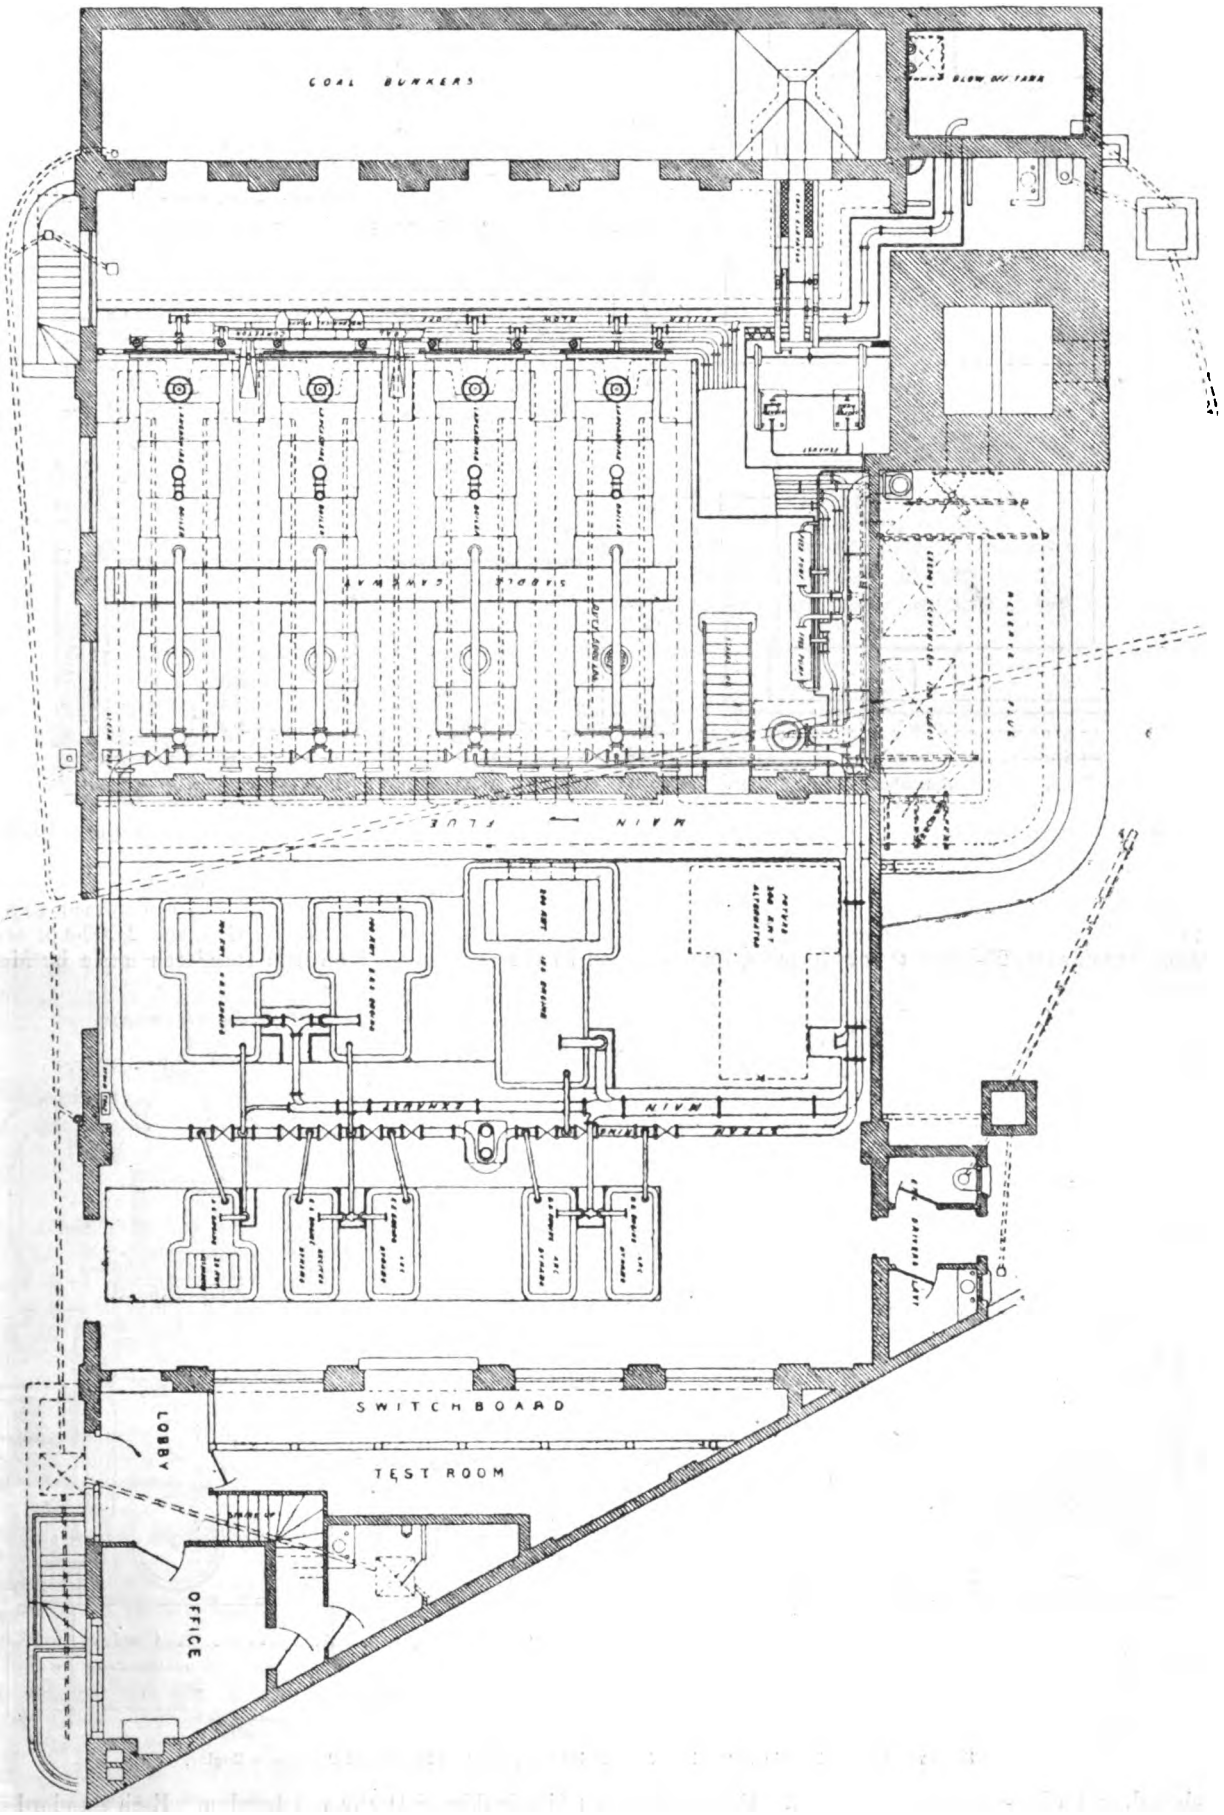
Private Lighting.

The current for the supply to private consumers is taken from the main switchboard by high-tension feeder cables to seven sub-stations, each of which supplies a small area, all the sub-stations to Siemens transformers, which convert the current from 2,000 to 105 volts, at which pressure customers are supplied from low-tension mains similar to the high-tension mains, but not so highly insulated. These



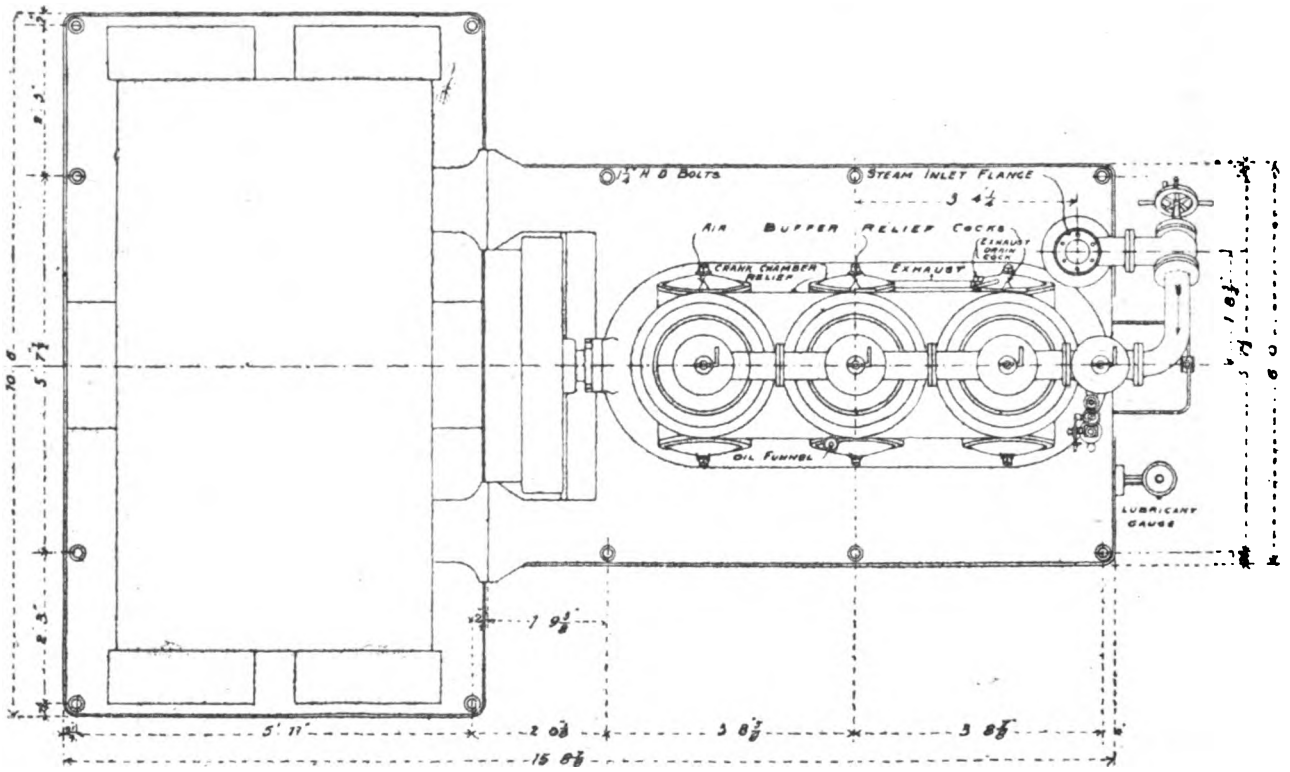
Hampstead Central Station.—General Plan, showing Arrangement of Plant.

seven sub-stations being connected by low-pressure distributing mains. The feeders are of Siemens H.C.N. concentric type, protected with iron armour, insulated with special fibrous material cased in lead, and are connected in feeders are laid direct in the ground, as are also the distributing mains. A pair of pilot wires is arranged in each feeder for measuring the E.M.F. at the sub-stations.

The seven sub-stations are situated (1) at the corner of

Digitized by Google

Arkwright-road and Fitzjohn's-avenue; (2) in Arkwright-road, about 100 yards from Finchley-road; (3) at the corner of Netherhall-gardens and Maresfield-gardens; (4) at the corner of Fitzjohn's-avenue and Nutley-terrace; (5) in Finchley-road; (6) at the corner of Fitzjohn's-avenue and Maresfield-gardens; and (7) in Finchley-road, near College-villas. These sub-stations comprise small brick chambers, 6ft. by 5ft., built under the pavement, access being obtained through a small manhole in the top. Each sub-station contains two 25-kilowatt transformers, a high-tension fuseboard, and a low-tension switchboard. From the latter the distributing mains are taken, and are so arranged that the supply to any length of distributing main between two sub-stations can be cut off for the purpose of connecting customers without interfering with any other part of the system. Each sub-station will supply 1,430 8 c.p. lamps. The total length of feeder main is a little more than 3½ miles, and will carry current for the supply of 17,000 8-c.p. lamps. The total length of low-tension main, which is of the triple concentric type for three-wire distribution, is 3½ miles, and this is sufficient to supply 10,000 8-c.p. lamps.



Hampstead Central Station.—Outline Plan of General Arrangement of IIIS Willans Engine.

Public Lighting.

At present the public lighting is confined to a portion of Finchley-road, where 22 Siemens 2,000-c.p. arc lamps have been erected on iron standards made by Messrs. A. Handyside, of Derby and London. Each standard consists of a cast-iron base surmounted by a wrought-iron stem and and an arched bracket, similar to those adopted at Ealing. The arc lamps are connected in series, and are supplied with current through a Siemens cable protected with iron armour and insulated with vulcanised rubber.

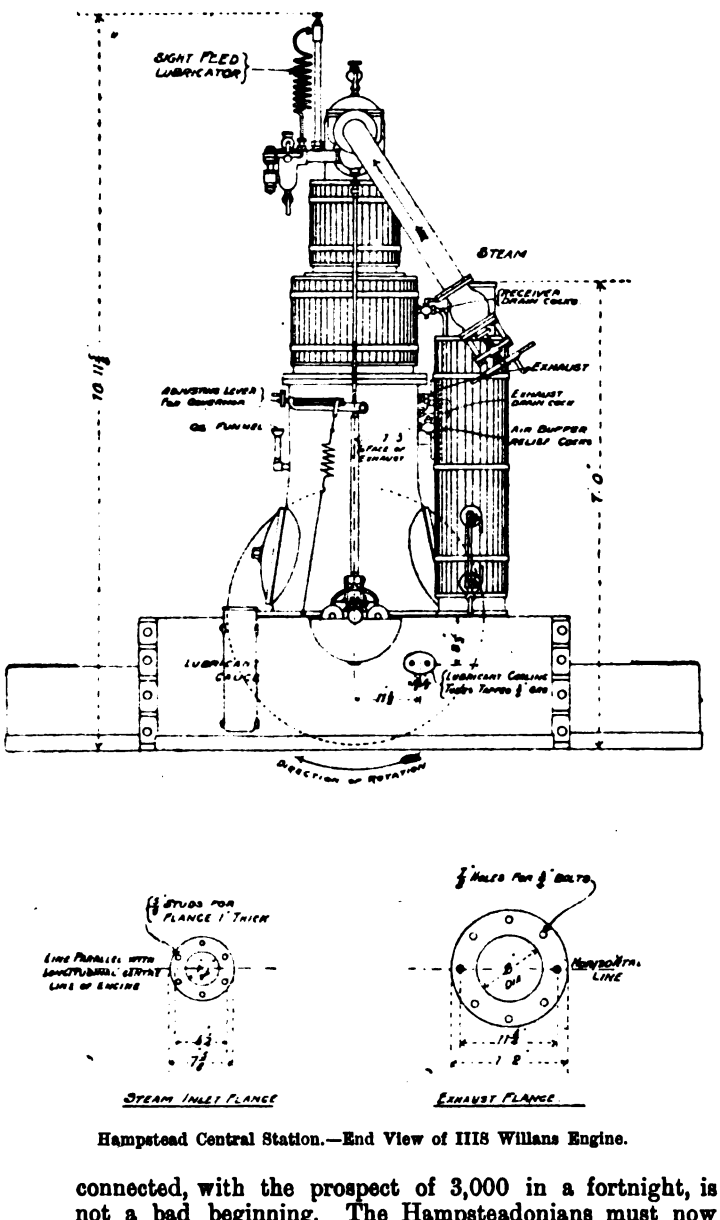
The contractors, Messrs. Siemens Bros. and Co., Limited, are to be congratulated for the very able manner in which they have carried out the whole of the work; the station is thoroughly equipped, and the plant is of the excellent workmanship characteristic of the company. Mr. W. H. Preece, who designed the station, has supervised the work and acted as consulting engineer to the Vestry. To the members of the Vestry congratulations must also be extended for having practically followed the increasing belief in the municipalisation of those undertakings which are of public benefit: and in doing this in the case of electric lighting, they have provided for the public not only the illuminant which is gradually making its way throughout the country, but they have also rendered available a supply of light which is the best and is as reliable as any other. Let the public now step in and take up a supply. To commence with 1,400 lamps



Hampstead Central Station.—End View of IIIS Willans Engine.

connected, with the prospect of 3,000 in a fortnight, is not a bad beginning. The Hampsteadonians must now awake, discard the vile gas now used, and ask the Vestry for a supply of the electric light.

PRACTICAL NOTES ON DYNAMO CALCULATION.*

XIV.

BY ALFRED E. WIENER.

30. *Mechanical Calculations about Armature.* (*a*) *Shaft.*—The length of the armature shaft varies considerably for the different arrangements of the field-magnet frame, and, owing to the length of the commutator, in equal output dynamos of the same design depends upon the voltage: and, therefore, a general rule for the length of the shaft cannot be given.

Its diameter, however, directly depends only upon the output and the speed of the dynamo, and can be expressed as a function of these quantities, different functions, however, being employed for various portions of its length. For while in the bearing portions, d_b (Fig. 43), torsional strength only has to be taken into account, the centre portion, d_c (Fig. 43), between the bearings, which carries the armature core, is to be calculated to withstand the torsional force as well as the bending due to the weight.

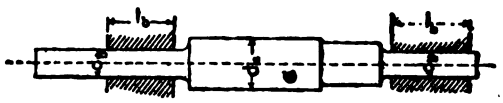


Fig. 43.

For steel shafts the author has found the following empirical formulæ to give good results in practice:

$$\text{For bearing portions: } d_b = k_8 \times \sqrt{W} \times \sqrt[4]{N} \quad . \quad (76)$$

where d_b = diameter of armature shaft at bearings, in inches;
W = output of dynamo, in watts;
N = speed, in revolutions per minute;
k_8 = constant, depending upon the kind of armature (see Table XXXVI.).

The value of k_8 varies between ·0025 and ·005, as follows:

Table XXXVI.—Value of Constant in Formula for Journal Diameter of Armature Shaft.

Kind of armature	Value of k_8.
High-speed drum	·0025
High-speed ring	·003
Slow-speed drum	·004
Slow-speed ring	·005

$$\text{For core portion: } d_c = k_9 \times \sqrt[4]{\frac{W}{N}} \quad . \quad . \quad . \quad . \quad (77)$$

where d_c = diameter of core portion of armature shaft, in inches;
W = output of machine, in watts;
N = speed, in revolutions per minute;
k_9 = constant depending upon output of machine (see Table XXXVII.).

This constant indicates the dependence of the diameter of the shaft upon the length between its supports, and since the weight supported and also the length supporting it increase with the output, it is evident that k_9 has a greater value the larger the output of the machine. For capacities up to 2,000 kilowatts k_9 numerically ranges between 1 and 1·8, thus:

Table XXXVII.—Value of Constant in Formula for Diameter of Core Portion of Armature Shaft.

Capacity in Watts, W.	Value of k_9.
Up to 1,000 watts	1
,, 5,000 ,,	1·1
,, 10,000 ,,	1·2
,, 50,000 ,,	1·3
,, 100,000 ,,	1·4
,, 200,000 ,,	1·5
,, 500,000 ,,	1·6
,, 1,000,000 ,,	1·7
,, 2,000,000 ,,	1·8

Considering the speeds given in Tables VIII., IX., and X., chapter 7, for various outputs, we obtain the following Tables XXXVIII., XXXIX., and XL., giving respectively the diameter of shafts for drum armatures, for high-speed ring armatures, and for slow-speed ring armatures.

For wrought-iron shafts the diameters obtained by formulæ (76) and (77), or those taken from Tables XXXVIII., XXXIX., and XL. respectively, are to be multiplied by 1·25; that is, increased by 25 per cent.

(*b*) *Driving Spokes.*—Ring armature cores usually are attached to the shaft either by means of spider frames or of skeleton pulleys. In both cases the driving of the conductors is effected by a number of spokes, which respectively form part of the spider itself, Fig, 44, or of a separate driving frame keyed to the skeleton pulley, Fig. 45.

In dimensioning these driving spokes, on the one hand

sufficient mechanical strength for driving should be provided, while on the other hand, if spiral winding is to be used, not more than necessary of the inner winding circumference should be made unavailable.

For the latter reason, the axial breadth of the spokes, b_s (Fig. 44 and Fig. 45 respectively), is to be made as large as the construction of the armature allows, and their thickness, h_s, calculated to give the requisite strength.

Multiplying equation (57) for the circumferential force per armature conductor (Chapter 23) by the number of effective conductors we obtain the total peripheral force of the armature:

$$F_p = f_p \times K \times \beta' = \cdot7375 \times \frac{E \times C}{S} \quad . \quad (78)$$

and allowing a factor of safety of about 4, we get:

$$F_p' = 3 \times \frac{W}{S}.$$

Dividing F_p' by the total number of spokes, we have the pull for each spoke, and this multiplied by the leverage gives the external momentum acting on each. The latter

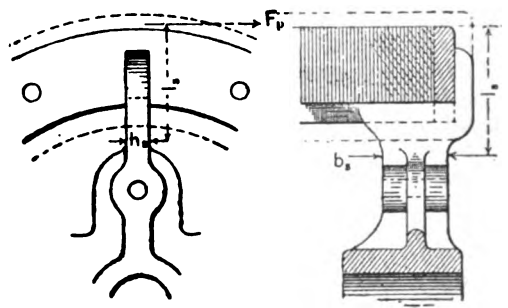

FIG. 44.

must be equal to the internal momentum—*i.e.*, the product of the modules of the cross-section and the safe working stress of the material. In consequence we have the equation

$$\frac{3 \times \frac{W}{S}}{n_s} \times l_s = \frac{b_s \times {h_s}^2}{6} \times Q;$$

or,

$$b_s \times {h_s}^2 = 18 \times \frac{W}{S} \times \frac{l_s}{n_s \times Q} \quad . \quad . \quad . \quad (79)$$

in which b_s = smallest width of spoke (parallel to shaft), in inches;

h_s = smallest thickness of spoke (perpendicular to shaft), in inches;

l_s = leverage at smallest spoke section—*i.e.*, distance of smallest section from active armature conductors—in inches;

n_s = total number of spokes per armature;

W = total output of dynamo, in watts;

S = conductor velocity of armature, in feet, per second;

Q = safe working load of material, in pounds per square inch.

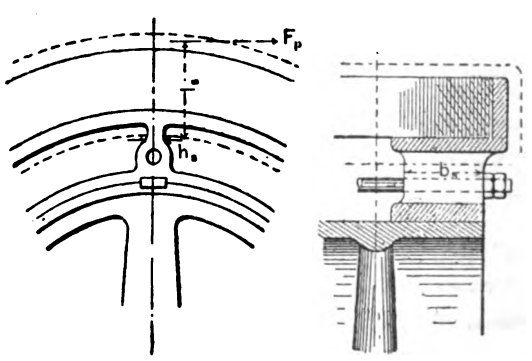

FIG. 45.

Cast iron.....	Q = 5,000lb. per square inch.
Brass	= 6,000lb. ,,
Phosphor bronze	= 7,000lb. ,,
Wrought iron.....	= 10,000lb. ,,
Aluminium bronze.....	= 12,000lb. ,,
Cast steel	= 15,000lb. ,,

For spiral windings, now, b_s, as stated above, is given by making it as large as possible, and from (79) we therefore obtain:

$$h_s = 4{\cdot}25 \times \sqrt{\frac{W}{S} \times \frac{l_s}{n_s \times b_s \times Q}} \quad . \quad (80)$$

For windings external to the core, h_s may be fixed, and then b_s calculated from

Digitized by Google

$$b_s = 18 \times \frac{W}{S} \times \frac{l_s}{n_s \times h_s^{\,2} \times Q} \quad . \quad (81)$$

For very heavy duty dynamos a larger factor of safety should be taken, say from 6 to 8; this will change the numerical coefficient of formulæ (79) and (81) into 27 to 36, and that of equation (80) into 5·3 to 6 respectively.

(*c*) *Bearings.*—To determine the size of the armature bearings, ordinary engineering practice ought to be followed. In machine design, on account of the increased heat generation at higher velocities, it is the rule to provide a larger bearing surface the higher the speed of the revolving shaft. This rule may, for dynamo shafts, be expressed by the formula:

$$l_b = k_{10} \times d_b \times \sqrt{N} \quad . \quad . \quad . \quad . \quad (82)$$

where l_b = length of bearing, in inches;
d_b = diameter of bearing, in inches, from formula (76);
N = speed of shaft in revolutions per minute;
k_{10} = constant depending upon kind of armature and on output of dynamo (see Table XLI.).

The numerical values of k_{10} range between ·1 and ·225 for high-speed armatures, and from ·15 to ·3 for slow-speed armatures, as follows:

TABLE XLI.—Value of Constant in Formula for Length of Armature Bearings.

Capacity in kilowatts.	Value of constant k_{10}.	
	High-speed armatures.	Slow-speed armatures.
Up to 5	·1	·15
,, 10	·1	·175
,, 50	·125	·2
,, 100	·15	·225
,, 500	·175	·25
,, 1,000	·2	·275
,, 2,000	·225	·3

Applying these values to formula (82) and using the journal diameters previously determined, the following Tables XLII., XLIII., and XLIV. are obtained, giving the sizes of bearings for drum armatures, high-speed ring armatures, and slow-speed ring armatures, respectively:

(*d*) *Pulley and Belt.*—The pulley diameter is determined by the speed of the dynamo and the linear belt velocity:

$$d_p = \frac{12 \times S_b}{\pi \times N} = 3{\cdot}7 \times \frac{S_b}{N} \; ; \quad . \quad . \quad (83)$$

d_p = diameter of pulley, in inches;
S_b = belt speed, in speed per minute (see Table XLV.);
N = speed of dynamo, in revolutions per minute.

TABLE XLV.—Belt Velocities for High-Speed Dynamos of Various Capacities.

Capacity in kilowatts.	Belt speed in feet per minute. S_b
Up to 5	2,000 to 3,000
2·5 ,, 25	3,000 ,, 4,000
10 ,, 100	4,000 ,, 5,000
50 ,, 500	5,000 ,, 6,000

The belt speed in modern dynamos ranges between 2,000ft. and 6,000ft. per minute, as above:
The pull at the pulley circumference, in pounds, is:

$$F_p = \frac{33{,}000 \times H.P.}{\frac{d_p \times \pi}{12} \times N} = \frac{33{,}000 \times H.P.}{S_b} = 44{\cdot}2 \times \frac{W}{S_b}$$

For an arc of belt contact of 180deg., which can safely be assumed for dynamo pulleys, the pull, F_p, is to be multiplied by 1·4 in order to obtain the tension on the tight side of the belt; hence the greatest strain upon the belt:

$$F_b = 1{\cdot}4 \times F_p = 62 \times \frac{W}{S_b}.$$

Allowing 300lb. per square inch as the safe working strain of leather, the necessary sectional area of the belt can be found from

$$b_b \times h_b = \frac{F_b}{300} = {\cdot}2 \times \frac{W}{S_b} \; ; \quad . \quad . \quad (84)$$

b_b = width of belt, in inches;
h_b = thickness of belt, in inches;
W = capacity of dynamo, in watts;
S_b = belt speed, in feet per minute (Table XLV.).

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
ther Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

BOUND VOLUMES.

Vol. XIII. of new series of "The Electrical Engineer" can e had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

SPECIFICATIONS.

To judge from the outcry—lately raised with ample justification in quarters well qualified to complain—against the too frequent absurdities of *soi-disant* consulting electrical engineers, there must be at least two distinctly vicious attributes that may be discovered in the characters of these gentlemen. In the first place, their absolute ignorance of *essentials* as compared with the mere frills or trimmings, which only entail useless expense without any material advantage to be gained thereby, is usually on a par with their entire confidence in the self-assertive ability so abundantly bestowed upon them by a nature that seems fond of freaks. Conceit in every line and a gratuitous assumption of superiority are commonplaces in the specifications drawn up by these individuals for the guidance (?) of contractors or engineers whom fate brings within their range.

Such trifles as elaborately printing a folio document, tied with red tape, and bearing outside a red seal (with green ribbons) somewhat smaller than a saucepan lid, with verbal gems inside—such as "Consulting Engineer, John Jorkins, Esq.; "Portable fittings to be based on Mr. John Jorkins's method," etc.—only serve to make the true engineer or hard-headed practical man smile on both sides of his mouth. When, however, ridiculous restrictions are enforced—as, for instance, a minimum coal consumption to be guaranteed—although no help be given in the matter of compounding or condensing, or even the cost of raw fuel *in situ*, the situation becomes more serious; and if hard-and-fast conditions of payment are insisted upon, the unfortunate contractor may consider himself well off at escaping with a *slight* money loss. Yet what is he to do? He cannot retire from business on a competency gained by hard work and fair dealing: efforts in these directions appear too often to result in a competency for someone else more unscrupulous.

This brings us to the second "grievous fault" to be found, we fear, in more than one case; and a far more serious piece of wrong-doing it is than that above named. Much as the trade owes to some half-dozen consulting engineers, whose record is blameless in every way, there are, it may be asserted, some who do not scruple to set up their own personal pecuniary advantage above the interests of their clients; not of course by "accepting insults" in the manner of the Lord High Everything Else in the "Mikado"—the very name of "commission" would cause them to throw up both hands and eyes in holy horror! There are easier and more polite methods than that. Smith's patent engines or boilers, Robinson's improved dynamos (lately patented), Jones's lamps (see specification No. 50,000,004, 1892), are all to be employed on the particular contracts which our "consulting" engineer may have on hand, and no one would dream of accusing the dear man of partiality unless they knew that Smith, Robinson, and Jones are nominees or friends of the consultant, whose name, of course, must not be associated with patent rights, although he may draw the royalties.

This is, however, only a single instance of "how

Digitized by Google

to do it," or from a slightly more moral standpoint of "how *not* to do it." If, speaking more broadly, we did not firmly believe in the capacity of natural law to assert itself sooner or later, and as an essential part of continued existence bring wrong-doing to its ultimate (sometimes *very* ultimate) punishment, life would really not seem worth living. Usually, however, it is the case that sooner or later the Adelphi drama is truly representative of life—virtue becomes victorious and villainy is vanquished. All we ask now is to let it be sooner rather than later.

STEEL v. IRON.

Even to-day we think it more than probable that nine-tenths of the electrical industry, or, to specialise more closely, of the dynamo makers and designers, are prepared to stake their word that there is no material so good, from an electrical standpoint, as soft wrought iron for the cores, poles, and polar extensions of dynamos: and the makers back up their word by using this type of iron, except for very cheap machines, or in cases where power costs little, and magnetic loss may therefore be disregarded.

We have lately, however, received some tabulated reports, accompanied by complete diagrams, concerning a series of tests undertaken by Mr. Kapp and Prof. Ewing upon a particular form of cast steel intended for use in this direction; and to judge from the results therein detailed, there would seem to be no reason for doubting the actual magnetic superiority of certain steels as compared with good wrought iron. The importance and value of such results will hardly require emphasising for those who know the difference in cost between somewhat complicated forgings (with the accompanying disadvantage of magnetic joints) and simple castings which avoid all joints of this kind.

In what manner such excellent results are obtained does not appear evident: we have no information as to whether the effect is reached by such methods as annealing, or whether it is due simply to an alloy such as aluminium. So long as the cost of the metal is not materially greater than usual, its exact constituents may remain the makers' secret: Sheffield will always be sure of orders when its works are able to turn out castings of this kind.

The chief advantage which they offer is a high permeability at such comparatively strong magnetisations as are used in dynamo magnets: this is considerably higher than that of good wrought iron. "Its permeability," says Prof. Ewing, "with respect to low magnetic forces, is somewhat less than that of wrought iron; with high forces the reverse is the case. From B=14,000 upwards, the permeability of this cast metal is superior to that of iron forgings, and it will consequently take up more magnetism for a given exciting current." The results show, for instance, that a force of 40 units produces a magnetic induction of 17,000, as against 15,000 to 16,000 in wrought iron, whilst an induction of 18,000 may be reached with a force of 68 units, whereas ordinary wrought iron would require at least 125 units for the same induction. The diagrams showing complete cycles of double magnetic reversal evince further good qualities of this metal so far as concerns the energy lost in hysteresis, but of course this is not a serious matter in the design or working of dynamo magnets. In five separate tests, the figures representing the area enclosed between the completed curves of magnetisation—*i.e.*, the energy expended in carrying the iron through the magnetic reversals—give a very regular curve; thus taking the positive and negative limits of magnetising force as 3·57, 5·93, 7·83, 15·6, and 37·0 for each cycle, and the similar limits of magnetic induction as 6,080, 9,400, 11,070, 14,500, and 16,800, the corresponding values for the energy lost are 2,780, 5,720, 7,470, 11,740, and 15,420.

A final advantage offered by these steel castings, to judge from the reports, appears to be of a mechanical nature: they can be made remarkably free from blowholes, whilst, in addition, a little care in moulding and casting ensures excellent surfaces, thereby effecting considerable economy of labour and time in the machine-shop. Provided, therefore, the actual cost of such castings can be kept down to the same as, or less than, that of forgings, there would seem to be great inducement for makers to employ them, not only in their own interest, but those also of their customers who have to pay for exciting current.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE PRICE OF GAS AND ELECTRIC LIGHT.

SIR,—Mr. Preece is reported to have stated that electricity at 6d. per B.T. unit is equal to gas at 3s. per thousand; but you will see from the enclosed cutting that the cost of electricity is *ten times* the cost of gas. Can you assist

A PUZZLED RATEPAYER.

[The cutting is an advertisement, which runs as follows: "Gas *v.* Electric Light.—A statement of fact.—A 16-c.p. electric incandescent lamp lasts on an average 1,000 hours, and absorbs 60 units of electricity in that time. A 60-c.p. incandescent gas lamp (the mantle of which lasts on an average 1,000 hours) consumes 3½ cubic feet of gas an hour, or 3,500 cubic feet in 1,000 hours. It may, therefore, be taken that three incandescent electric lamps are required to give the light of one incandescent gaslight. This means that, taking 3s. per 1,000 cubic feet as the average price of gas, and 6d. a unit as the average price for electric current, the cost of electric light is 10 times the cost of incandescent gaslight."]

WORCESTER.

The number of central stations being completed and set in operation at the present time is being rapidly added to. Last week we fully described and illustrated the Ealing electricity works, which were opened on Wednesday, and this week we deal similarly with the Hampstead central station, which was inaugurated on Monday. Before our next issue, the electricity works at Worcester, which pressure on our space prevents our dealing fully with in this issue, will have been opened. Next week we hope to be able to publish a detailed description of the novel features of the Worcester central station.

JAMES PRESCOTT JOULE.*

BY LORD KELVIN.

The unveiling last December of a statute of Dr. James Prescott Joule at Manchester, England, has given that city the possession of a work of art which will ever remain an ornament and an honour to it.

Joule's work began in Manchester, was carried on in Manchester, and finished in Manchester. It began very early, when he was only 19 years of age. He was not altogether a self-taught man in science. After a good ordinary school education, he had the inestimable benefit of the personal teaching of Dalton in chemistry. He and his elder brother, Benjamin, were favourite pupils of Dalton. They went to his house in the rooms of the Literary and Philosophical Society of Manchester for regular daily lessons, and were a little disappointed at first when they found that Dalton, instead of introducing them straight away to the grandeur of the atomic theory of chemistry, kept them to the grindstone, forced them to do their additions correctly, and held up to them, as something essentially necessary for them to learn, the practice of trigonometry and the logarithmic tables. James Joule and his brother got great good from that early severe, almost hard, training by Dalton. They were both full of original brightness and acuteness in their observations. They went through the country, even before they came to be pupils of Dalton, making memoranda of what they saw and heard—an aurora borealis or a wonderful thunderstorm, or sounds of artillery or lightning, they could not tell which.

The two brothers continued pupils of Dalton until the failure of his health; but for a year after that, and no doubt to the very end, they continued to receive ideas from that great man. It must not be thought that Dalton only taught them arithmetic and trigonometry. I rather emphasise that point with an eye perhaps to the young men who aspire to follow in Joule's footsteps, and upon whom I wish to impress the conviction that it was hard work, early begun and persevered in and conscientiously carried out. That is the foundation of all great works, whether in literature, philosophy, or science, or in doing good to the world in any possible way. In electricity and electromagnetism Joule, I think I may say, was wholly self-taught. All he knew he learned from his own reading—from reading in text-books and in Sturgeon's "Annals of Electricity," and also from conferences with Sturgeon himself. The Literary and Philosophical Society of Manchester has the distinguished honour of having been the cradle of Joule's scientific childhood when it was Dalton's home, and of being afterwards Joule's life-long scientific harbour. From those early days he kept constantly in touch with that society. Many of his most important papers were first given to the world there, and during the last years of his life he was an exceedingly regular, it might almost be said a constant, attendant at the meetings of the society. An interesting and sympathetic memoir of Joule, with much important scientific information and judgment regarding his work, by Prof. Osborne Reynolds, constitutes the sixth volume of the fourth series of its *Memoirs and Proceedings*.

A great surprise that came out very early in Joule's work was burning without heat—an absolutely novel idea which Joule developed most wonderfully and most magnificently by his experiments on the generation of heat in the voltaic battery. Joule was the first to develop the idea, and it came to him not as a bright flash of genius, but as the demonstrated result of years of hard, measuring, calculating work. This burning without heat was a fundamental idea that pervaded all Joule's work. A few years later he expanded it in an admirable way. About 1884, in a joint paper by himself and Scoresby, "On the Mechanical Powers of Electromagnetism, Steam, and Horses," he brought out the startling but truly philosophical idea that when a man or any other animal walked uphill, only a part of the heat of combustion of his food was developed, and that it was only when the body was quiescent, or walking about on a level, or going down hill that the chemical attraction between the food and the oxygen dissolved in the blood developed its whole energy in animal heat. He showed, further, that a horse or a man employed in doing mechanical work against resistance was more economical of fuel than was any steam-engine hitherto realised. This was a very far-reaching idea, and seemed to hold out prospects of greatly advancing the efficiency of the steam-engine. That promise has not been lost.

It is due to Joule more than to any other individual that the great improvement of surface condensation is now universal, although it was very rarely practised before 1860 or 1862. Between 1855 and 1862, Joule and I had a small steam-engine fitted up in the stable of his father's house, Oakfield, for use in our joint investigations on the thermic effects on fluids in motion. To that little steam-engine Joule applied a surface condenser on an entirely new principle and plan, which gave us such good results that, starting from it, he undertook a special investigation on the surface condensation of steam with the assistance of a grant from the Royal Society for the purpose. The results of this very elaborate investigation, communicated to the Royal Society on December 13, 1860, and published in the *Philosophical Transactions*, have proved to be of enormous practical importance. They led directly and speedily to the present practical method of surface condensation.

But I have not yet touched upon Joule's great fundamental discovery, the discovery which is first in every one's mouth when asked what was Joule's work—the mechanical equivalent of heat. It was not merely by a chance piece of experiment or of guessing that he stumbled on a result which was afterwards found to be of great value. It was measurement, rigorous experiment and observation, and philosophic thought all round the field of physical science that made the discovery possible to him. Very early, however, in his working time Joule brought out the mechanical equivalent of heat, and in a paper at the British Association of Cork, in 1843, published afterwards in the *Philosophical Magazine*, he gave the number "770." Six years later a second determination gave him a result about one-third per cent. larger, and 29 years later he completed a third determination. The result of this final investigation of Joule's is 772·43 Manchester foot-pounds for the quantity of heat required to warm from 60deg. to 61deg. F. 1lb. of water weighed in vacuum, which is about $\frac{1}{200}$ per cent. greater than the result of 1849 expressed in the same term.

In the year 1894 a great theory was originated by a very young man, who died only a few years later—Sadi Carnot, son of the Republican War Minister and uncle of the late President of the French Republic. It was he who made "Carnot's theory" a household word throughout the world of science. Carnot's theory gave an important fundamental principle regarding the development of motive power from heat. Joule's work, on the other hand, so far as the mechanical equivalent was concerned, was the generation of heat by mechanical work. It was quite the middle of the century before Carnot's theory began to attract attention; but Joule was early made acquainted with it, and after fighting a little against it, as differing from his own theory, he, of all others, took it up in the most hearty manner. I can never forget the British Association at Oxford in the year 1847, when in one of the sections I heard a paper read by a very unassuming young man who betrayed no consciousness in his manner that he had a great idea to unfold. I was tremendously struck with the paper. I at first thought that it could not be true, because it was different from Carnot's theory, and immediately after the reading of the paper I had a few words of conversation with the author, James Joule, which was the beginning of our 40 years' acquaintance and friendship. On the evening of the same day that very valuable institution of the British Association, its conversazione, gave us opportunity for a good hour's talk and discussion over all that either of us knew of thermodynamics. I gained ideas which had never entered my mind before, and I thought I, too, suggested something worthy of Joule's consideration when I told him of Carnot's theory.

Then and there in the Radcliffe Library, Oxford, we parted, both of us, I am sure, feeling that we had much more to say to one another and much matter for reflection in what we had talked over that evening. But what was my surprise a fortnight later when, walking down the

* From *Cassier's Magazine* for September.

Digitized by Google

valley of Chamounix, I saw in the distance a young man walking up the road towards me and carrying in his hand something which looked like a stick, but which he was using neither as an alpenstock nor as a walking-stick. It was Joule with a long thermometer in his hand, which he would not trust by itself in the *char-à-banc* coming slowly up the hill behind him, lest it should get broken. But there, comfortably and safely seated on the *char-à-banc*, was his bride—the sympathetic companion and sharer in his work of after years. He had not told me in Section A or in the Radcliffe Library that he was going to be married in three days, but now in the valley of Chamounix he introduced me to his young wife. We appointed to meet again a fortnight later at Martigny to make experiments on the heat of a waterfall (Sallanches) with that thermometer; and afterwards we met again and again and again, and from that time, indeed, remained close friends till the end of Joule's life. I had the great pleasure and satisfaction for many years, beginning just 40 years ago, of making experiments along with Joule which led to some important results in respect to the theory of thermodynamics. This is one of the most valuable recollections of my life, and is, indeed, as valuable a recollection as I can conceive in the possession of any man interested in science. Joule's initial work was the very foundation of our knowledge of the steam-engine and steam power. Taken along with Carnot's theory it has given the scientific foundation on which all the great improvements since the year 1850 have been worked out, not in a haphazard way, but on a careful philosophical basis. James Watt had anticipated to some degree, in his compound engine and his expansive system, the benefits now realised; but he was before his time in that respect, and he had not the complete foundation which Joule's mechanical equivalent and Carnot's theory have since given for the improvement of the steam-engine.

THE BOARD OF TRADE STANDARDS AND STANDARDISING LABORATORY.

(Continued from page 371.)

Turning now to the "standards" room, a description must be given of the two main standards—the ampere standard and the volt standard; these, with the standard ohm as verified during the present year, giving the permanent units of current, E.M.F., and resistance.

Construction and Use of the Instrument for Determining the Standard of Electrical Current.

The standard ampere-meter is a truly magnificent piece of apparatus. We illustrate it in perspective with some of the chief details. Its construction is practically as follows:

A sensitive balance suitable for the accurate determination of weights up to five kilogrammes, with a beam 16in. in length between the knife-edges, from which the scale pans, S S (Fig. 1), are hung, is fixed on an upper horizontal platform of marble, supported on four marble columns at a height of 2ft. 3in. above a similar platform fixed on a suitable stone pier, bedded solidly in a mass of concrete, and kept clear from contact with the wooden floor of the laboratory.

On the lower platform (see Fig. 2) is placed on three supports—details of which are given below—a cylinder of white statuary marble, partly hollow. The cylinder is thoroughly impregnated with paraffin wax. A block of ebonite, *e* (Figs. 1 and 2), is fixed on one side of the cylinder, and serves as a terminal board.

Two circular grooves are cut completely round the cylinder, in which are wound coils of No. 18 standard wire gauge, 0·012 centimetre diameter, insulated with two coverings of white silk. The wire was passed through a bath of shellac and alcohol as it was wound on the marble, and each layer was well coated with the same material when in its place.

Each coil has 16 turns per layer, and 16 layers of wire. The coils are both wound in the same direction, and the outer ends are strained tight and secured to the terminals, *t t* (Fig. 3). The inner ends are passed through the marble and secured to bolts in connection with terminals, *i i* (Fig. 2).

Between the grooves on the marble cylinder, at points equidistant from each other, are bored through the marble three sighting holes, one of which is shown at *h*, Figs. 1 and 2. These holes are closed on the inside by glass, the exact centres being indicated by the intersection of two straight lines engraved in the glass, and also by the angle of a quadrant of tinfoil affixed to the glass.

A circular coil, shown in sectional elevation at C, Fig. 2, and of the dimensions given, is suspended from one end of the beam of the balance by means of three gilded phosphor-bronze wires, 0·086 centimetre diameter, *w*, *w*, *w* (Fig. 2). These wires pass through an aperture in the upper marble platform.

The wire in this coil is the same as in the fixed coils, and is similarly insulated and varnished. There are 18 turns of wire in each layer, and 18 layers. Each complete layer was allowed 24 hours to dry after being coated with shellac varnish before the next layer was put on. The coil is covered with a taping of silk ribbon, closely laid on to overlap, and varnished with shellac in alcohol four coats, each being allowed to thoroughly dry before applying the next one. The ends of the coil are brought out next each other on the upper surface at *l*, Fig. 2. A considerable length of wire is left for each end, and is formed into a spiral and then projected horizontally to the centre of the coil, where the stiff wires terminate, and flexible connections are made by three silk-covered silver wires No. 40 S.W.G. from each to the posts, *p* (Fig. 2), which are connected to terminals, *n n*.

Three ebonite blocks (*b*, Fig. 2) are fitted over the coils as shown, and secured by a lashing of silk thread, the suspended wires being attached to brass eyelets screwed into the ebonite. At *d*, *d*, *d*, Fig. 2, are shown ivory cranks for effecting the vertical adjustment of the suspended coil.

The details of the attachment of the suspending wires to the balance are shown on Fig. 4; *r*, *r*, *r*, are ivory rings which are hooked on to the three-legged fitting, *f*, this being hooked to the stirrup, *j*, hung on the knife-edge of the beam. The scale pan, S, is also hung from *f*. On the upper part of each ebonite piece, *b*, facing the sighting hole, *h*, is fixed a mirror, *m*, the centre being marked by the intersection of cross-lines and by the angle of a quadrant of tinfoil.

The proper adjustment of position of the suspended coil is indicated by the coincidence of the angles of the tinfoil quadrants on the mirrors, M, and the glass back of holes, *h*, when the eye is so held that no reflected image can be observed.

A means of fine horizontal adjustment is provided in the supports of the marble cylinder, which are three short slate cylinders, *k*, *k*, *k* (Fig. 2), having projections from their upper and lower surfaces, the upper projection being excentric and fitting in a hole in the bottom of the marble cylinder, and the lower projection being concentric and fitting in a radial groove in the marble slab. An iridio-platinum weight is suspended on each side of the scale beam from a system of levers, by means of which it can be lowered into its respective scale pan, and released from the outside of the case.

The marble cylinder is enclosed by means of three sheets of plate glass which slide in grooves cut in the marble platforms, and when in position are in contact with the sides of the three pillars adjacent to the cylinder, the plan of this enclosure being an equilateral triangle with the axis of the marble cylinder at its centre. The planes of the three glass sheets are respectively parallel with those of the glass at the back of the sighting hole viewed through them.

The balance is enclosed within a case of mahogany and glass (see Fig. 1) and arrangements are made, as indicated, for manipulating the rider weights of the balance and the ampere weight from the outside of this case. The whole enclosure is fairly dust-tight, and sufficiently air-tight to prevent any disturbance of the weighing operations by currents of air. The connections to the reversing switch, Z, are brought outside the enclosure by means of rods passing through the pillar adjacent to the ebonite block, *e*. Fig. 3 shows these connections and the direction of the current through the various parts of the apparatus, the lower arrows

Digitized by Google

over the fixed coils showing the alteration of direction caused by operating the switch.

Auxiliary Current Balance.

In the construction of the standard ampere-balance the chief object aimed at has been the securing of the greatest possible constancy and precision of determination. On account of the slow period of vibration of the beam, however, the use of an auxiliary instrument has been found advantageous.

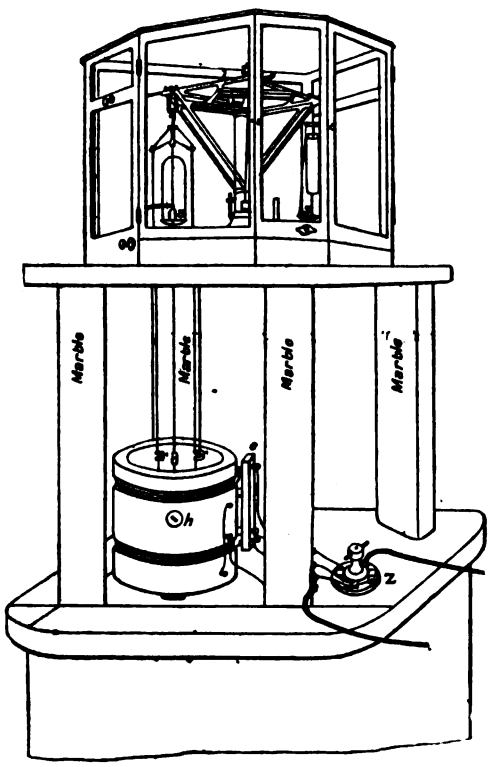

Fig. 1.

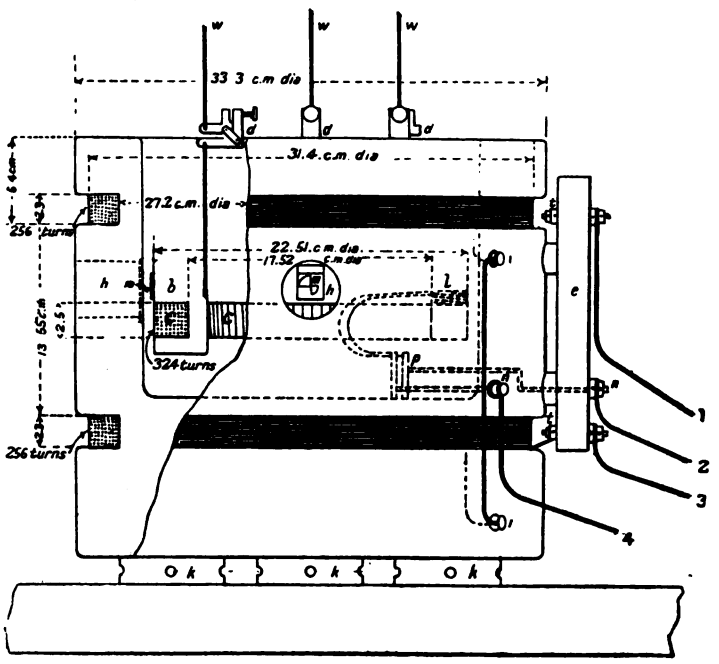

Fig. 2.

This is a special form of Lord Kelvin's current balance instrument arranged to balance with a current of one ampere passing through the coils when a certain weight is applied to one end of the beam, equilibrium being also maintained when, with no current passing, this same weight is applied to the other end of the beam.

Use of the Ampere Standard.

In using the apparatus thus described the standard balance, auxiliary balance, and the instruments to be standardised are connected in circuit with a sufficient number of accumulators and an adjustable resistance, part of which is capable of continuous variation. The whole circuit is arranged so that a current of approximately one ampere will pass on completion of the circuit. This current is allowed to pass continuously for at least one hour, being directed through the coils of the standard, so as to increase the force of gravity on the suspended coil, and the counterweight in the right-hand pan being adjusted from time to time.

At the end of this preliminary period the current is stopped for a short time to take a reading of the zero of the auxiliary balance, and apply a correction by means of the rider weight, if necessary. The current is then again put on, and as rapidly as possible regulated by means of the adjustable resistance to exactly the value of one ampere, as indicated by the auxiliary balance.

The counterweight in the right-hand pan, standard balance, is also exactly adjusted. The switch, Z, is then operated to reverse the current in the fixed coils, and at the same time the weight, A, is lowered into the left-hand scale pan. The balance should then still be maintained when the current, after adjustment, if requisite, is exactly one ampere by the auxiliary balance.

Construction and Use of the 100-Volt Standard.

We may next enter upon a description of the 100-volt electrical standard: the instrument itself is shown in plan and sectional elevation in Figs. 10, 11, and 12. It consists of:

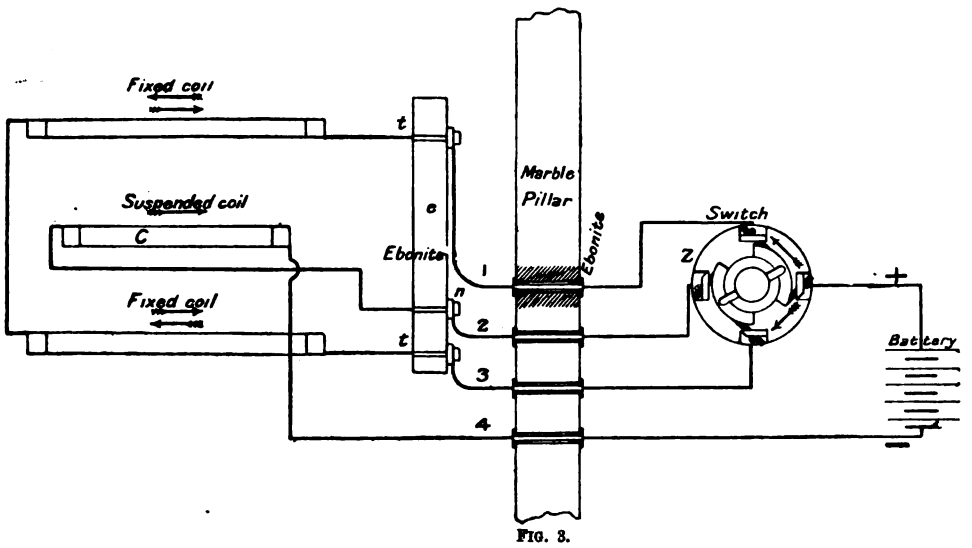

Fig. 3.

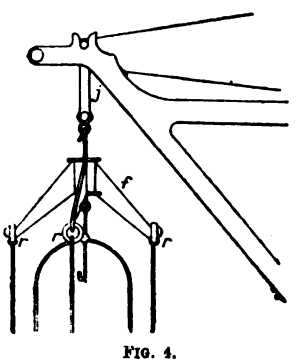

Fig. 4.

(*a*) An arrangement of 10 parallel vanes shaped like the moving portion of Sir W. Thomson's quadrant electrometer fitted on an axis passing through the centre of gravity of each vane, and separated by distance-pieces to a distance of nine millimetres apart.

(*b*) On the same axis is fixed the aluminium frame of a

Digitized by Google

concave mirror 19 millimetres in diameter and about 61 millimetres focal length, which is held in the frame by means of three light phosphor bronze springs.

(*c*) This arrangement is suspended by means of a wire ·05 millimetre in diameter and 18 centimetres in length, formed by an alloy of 10 parts of iridium to 90 parts of platinum, attached to the end of the axis above the mirror, so that the axis hangs in a vertical line.

(*d*) The upper extremity of the suspending wire is fixed to the centre of a circular brass plate having teeth cut in the circumference into which a tangent screw is geared so as to enable the end of the wire to be rotated in the horizontal plane for the horizontal adjustment of the vanes.

(*e*) The vertical adjustment of the position of the vanes is accomplished by the raising or lowering of the platform on which the circular brass plate mentioned above is pivoted by means of three screws for raising and three for lowering. These screws regulate the distance of the platform above a similar platform fixed by means of three supports to the framework of the instrument.

(*f*) The vanes are suspended so as to slightly enter at the zero position of the instrument into the spaces between two sets of 11 thin polished brass plates shaped as quadrants of a circle, which are fixed horizontally one above another to a vertical support. These two sets of plates are in metallic connection, and are carefully insulated from the framework of the instrument.

(*g*) In order to reduce the vibration of the suspended system and the time which must elapse before an accurate observation can be taken, a thin horizontal brass disc is suspended in refined mineral oil, contained within a glass vessel by means of a wire attached to the lower portion of the axis of suspension of the vanes.

(*h*) The suspended system and quadrants with their supports are enclosed in a brass case, having in front of the mirror a rectangular window of parallel worked glass. A hole is cut in this case for the insertion of a key fitting the squared arbor of the tangent screw.

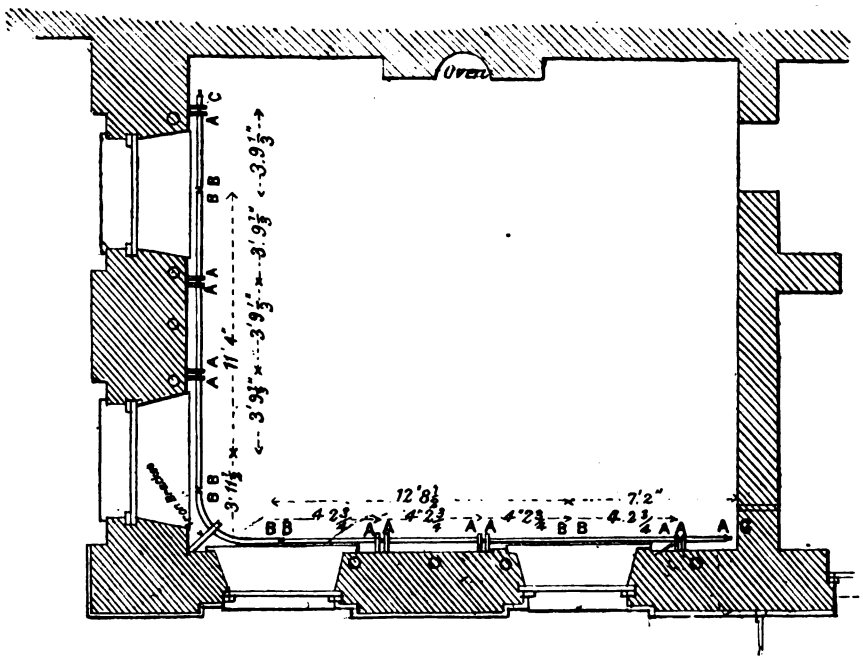

FIG. 5.

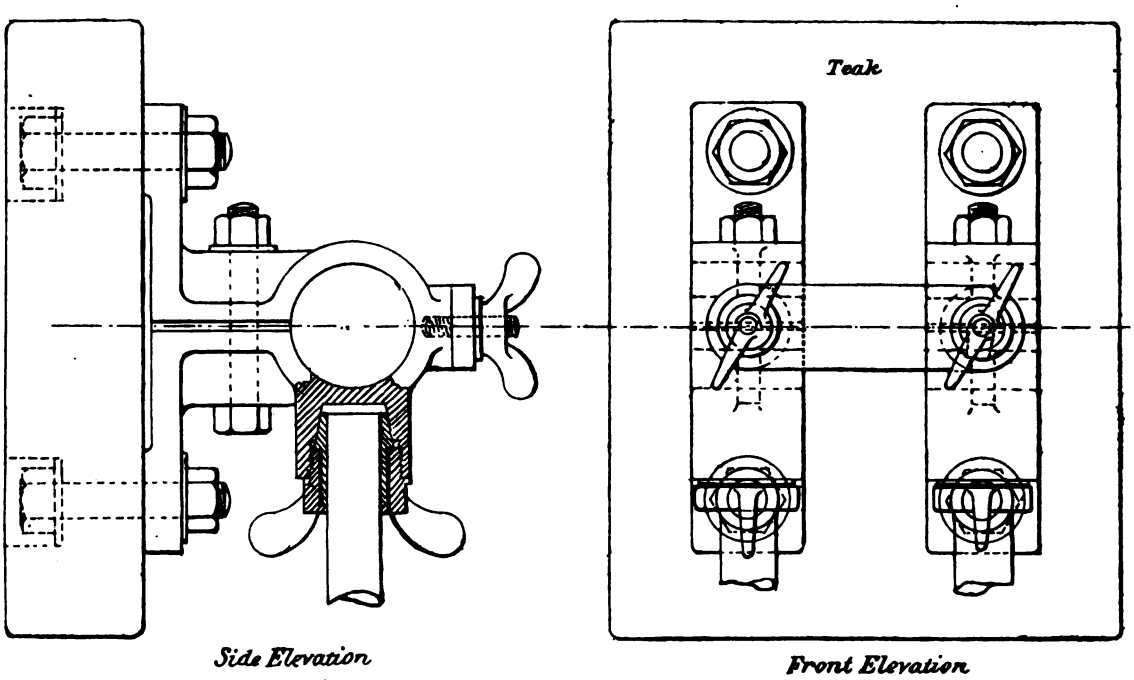


FIGS. 6 AND 7.

(*i*) The terminals by means of which connection is obtained with the vanes and quadrants are fixed on a thick piece of polished ebonite projecting beyond the brass cover. One terminal is in connection with the metal framework, the other is entirely insulated, and a tongue of brass, or switch, connected by means of a brass rod with the two sets of quadrants can be turned so as to make contact either with the insulated or with the uninsulated terminal.

(*k*) The arrangement described above, forming the electrical portion of the instrument, is mounted near the

Digitized by Google

apex of a framework of brass in the form of a circular arc, which rests by means of three feet on a horizontal slab of polished marble supported on a large block of Portland stone on a concrete foundation. A screw thread is cut on the feet for accurate levelling of the framework, to which two spirit-levels are attached.

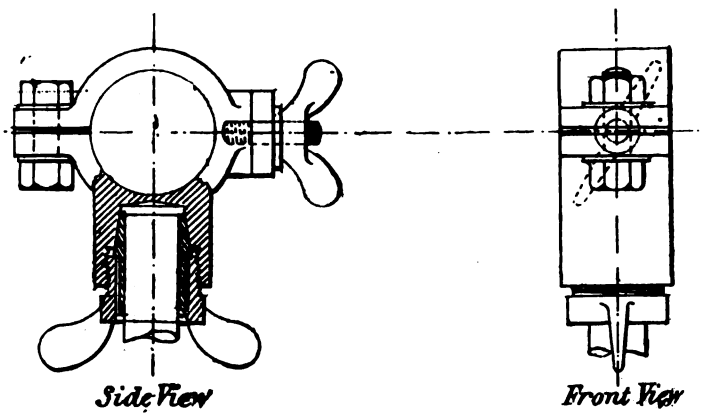
(*l*) On a support attached to the centre of the curved portion of the framework is fixed the observing portion, consisting of a magnifying eye-piece in front, in the focus of which is stretched a vertical copper wire ·06mm. in diameter.

(*m*) At each end of the arc is erected a vertical support, to which is fixed a tablet of brass with the surface facing towards the mirror platinised. On each of these faces is engraved a vertical line. These lines form the fiducial marks—that on the left of the observer giving the zero position, and that on the right the correct position for 100 volts pressure. The distances from the mirror of these tablets and of the sighting wire is adjusted so that the image of the line on the tablet when the mirror is at the proper angle coincides with the sighting wire.

Use of the Instrument.

The instrument is brought into accurate adjustment as regards level and position of the suspended system. The vertical adjustment of the latter is obtained by trial. The vanes are kept at equal distances from the quadrants above and below, this position giving minimum sensibility. The horizontal adjustment of the suspended system is obtained when the image of the zero fiducial mark produced by the mirror exactly coincides with the sighting wire, the switch being turned so as to connect the quadrants with the metal framework of the instrument. The levelling of the framework and vertical adjustment of the suspended portion of the instrument were carefully attended to when the instrument was first set up, and these adjustments have since that time remained constant, but the horizontal adjustment of the suspended system requires occasional attention from time to time.

In taking readings, arrangements are made for obtaining a pressure which can be continuously varied from about



FIGS 8 AND 9.

98 to 102 volts. This pressure is applied to the 100-volt standard and to the instruments to be compared with it, and is adjusted until the image of the fiducial mark indicating 100 volts pressure exactly coincides with the sighting wire by observation through the eye-piece. This coincidence is maintained by adjustment of the pressure, if necessary, until the expiration of five minutes from the time of first applying the pressure, when, if there is no visible vibration of the mirror, the pressure is exactly 100 volts.

In arriving at the value of the 100-volt standard, this instrument was checked and compared a number of times with Cardew voltmeters, the main readings being first taken with standard Clark cells as against the mercury ohm resistance. A sub-standard voltmeter, reading from 20 to 70 volts, is in use for ordinary work; and for high potentials there is a Thomson electrostatic voltmeter of vertical type capable of registering up to 10,000 volts.

Other Instruments, Etc.

In the standards room, as already mentioned, a series of instruments is ranged round the wall on benching, and supplied with current from an overhead Ferranti concentric main. Fig. 5 shows a plan of the room with this main in position; and Figs. 6, 7, 8, and 9 give details of the ingenious coupling adopted in order to secure a good contact between the main and branches leading downwards to each instrument. The main itself is designed to carry currents up to 500 amperes. From it a supply is taken to five instruments used as working sub-standards, and ranging in capacity as follows:

1. ·001 to 1 amperes
2. 1 to 5 „
3. 5 to 30 „
4. 25 to 100 „
5. 100 to 600 „

whilst the largest, measuring from 500 to 2,500 amperes, has special leads of copper strip brought up to it from

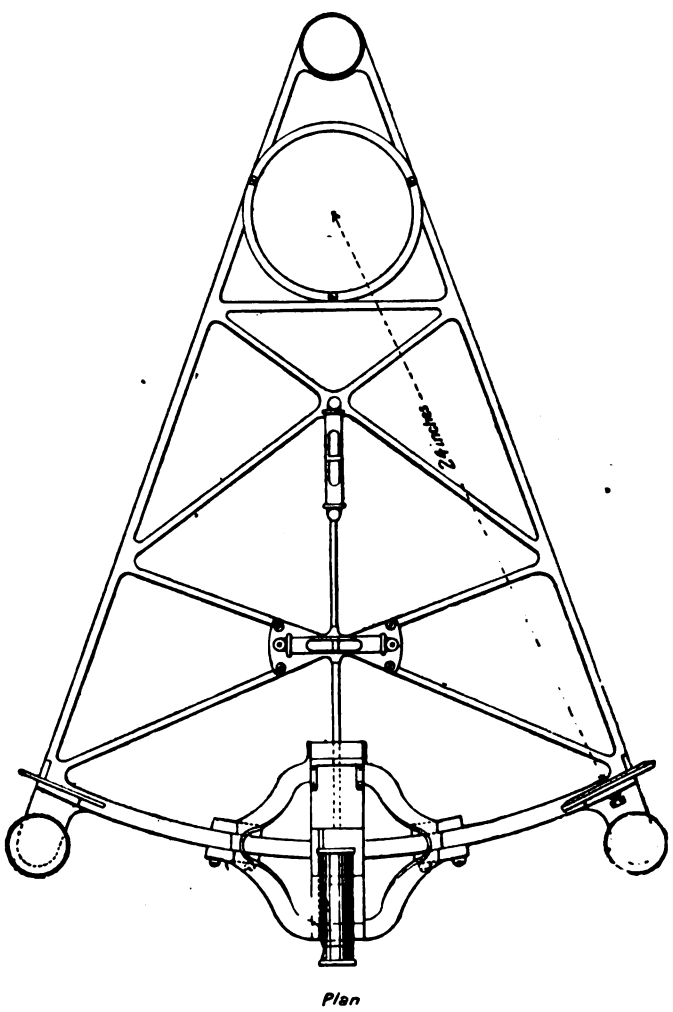


FIG. 10.

the battery mains. These instruments are all of the Thomson balance type.

One corner of the standards room is occupied by an arrangement for registering potentials up to 2,100 volts by means of Cardew voltmeter tubes set in series one with another, the indicating device being left on the end ones only. There are 12 tubes and two indicators, which may be coupled in series or parallel.

The other corner is fitted up with a series of switch and resistance gear to be used with the motor and dynamos already described. The first arrangement consists of adjustable carbon and platinoid resistances for insertion in the main or armature circuit of the motor; the second, of two variable iron wire resistances for insertion in the motor field circuit. The third comprises an adjustable iron wire and water resistances in the alternator field circuit; whilst the fourth consists of a variable iron wire and platinoid resistance in the field circuit of the high-pressure (2,000 volt) continuous-current machine. By the employment of these regulating devices the currents used

Digitized by Google

in the testing work may be altered as desired in almost any manner.

Turning now to the other departments of the laboratory, space will only allow somewhat brief mention of the leading features to be noted.

One small room is devoted to the measurement of resistances, and the illustration which we give in Fig. 14 is taken from a photograph of the arrangement used in obtaining the standard ohm. The latter, indeed, is shown in the foreground on the right. The apparatus includes a Carey-Foster bridge—seen in the centre—the galvanometer, lamp and screen, with resistances to be tested in the foreground. One improvement to be noticed is the bringing forward of the screen right in front, whilst the galvanometer itself is in the background. The spot of light may thus, being nearer to the operator, be more easily watched, whilst the galvanometer is protected by greater distance from small fluctuations due to "personal," if not "bodily," magnetism.

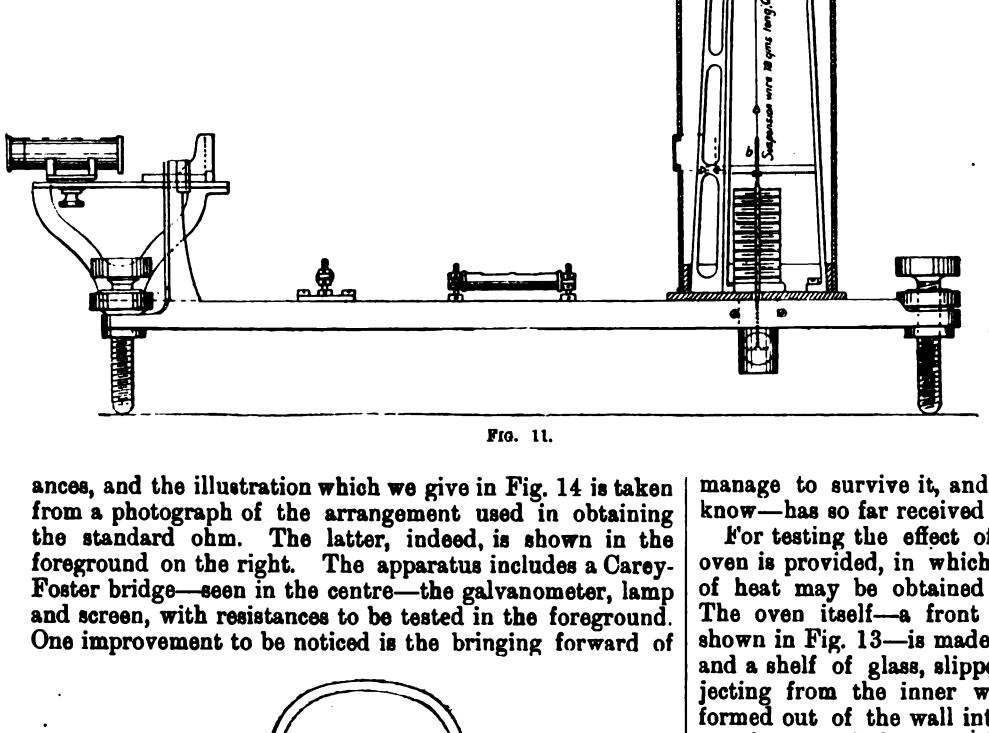

FIG. 11.

FIG. 12.—Showing Angle between Mirror and Vanes at Zero Position of Instrument.

FIG. 13.—Plans on Lines A B and C D.

Not the least important department of the whole laboratory—at any rate, to the electrical trade in general and instrument-makers more particularly—is the verification room, known to some as the "Chamber of Inquisition." Here the commercial electricity meters for which official sanction is sought, undergo crucial tests, both electrical and mechanical. Many there are that come to trial, but few manage to survive it, and one only—as our readers well know—has so far received official sanction.

For testing the effect of heat upon their indications an oven is provided, in which practically any desired degree of heat may be obtained by means of Bunsen burners. The oven itself—a front view and plans of which are shown in Fig. 13—is made of fireclay, with a glass front and a shelf of glass, slipped on to a couple of ribs projecting from the inner walls. At each side, in recesses formed out of the wall into which the oven is built, there are four vertical rows of burners directed against the exterior walls of the oven, and corresponding burners are fixed underneath also.

It would, of course, be against all law and order to give details of what may be seen going on in the verification room: various meters are still under test, but their design and makers must remain undetailed. We need only say, in conclusion, that a visit to this laboratory gives rise to a feeling of absolute security as to the careful and accurate work involved in properly carrying out the duties which have been laid upon the Board of Trade in this direction.

NEW CLOSED-CONDUIT SYSTEM.

There has been in operation for some months, in connection with the Lyons Exhibition, a new closed-conduit electric tramway system devised by Messrs. Claret and Wuillemier. According to this method, the electric motors on the cars are connected with the generating plant at the station by means of contacts or sectional rails laid between the track rails on the street-level, and which are brought into circuit successively and automatically during the short time of the passage of the car over the sectional rails. The line is double, and about two miles in length. The generating station is within the exhibition grounds, motive power being obtained from a Delamarre-Deboutville and Malandin 100-h.p. gas-engine using low-grade gas. This engine drives a Thury six-pole dynamo of 175 kilowatts.

The gauge of the line is one metre, and the rails are laid in lengths of 10 metres. In the centre of the track are placed the before-mentioned contact-pieces, consisting of sections of inverted rails 2·8 metres in length, and laid at intervals of three metres apart. These are insulated from each other and from the rails of the track by wooden pavement arranged in bitumen. Feeding-wires run from these contact-pieces in a wooden channel to the conductor,

receiving current at a pressure of 500 volts. The return current passes along the rails of the track. We give, in Fig. 1, a section of the roadway showing the distributor and cables.

By means of these automatic distributors, which are placed at stated intervals along the line, the sectional contact rails are brought into the circuit successively, only one section being alive at any one time. The details of the distributor, which is placed at distances of 100 metres, are shown in Fig. 2; Fig. 3 represents its connections, Fig. 4 is an elevation and plan of the distributor, and in Fig. 5 is illustrated the method of collecting the current. There are 12 cars in operation on this system.

THE UTILISATION OF TOWN REFUSE FOR GENERATING STEAM.*

BY T. W. BAKER, B.A.

The practice of the larger southern towns in England is that all fluid waste from dwellings is called sewage, and its disposal is provided for in these towns by different systems of treatment; but there are even now some towns in the North where the pail system is still in use. The class of refuse treated under the latter system is not included in this paper, but what will be considered consists of the usual ashbin contents, street sweepings, and sludge. The disposal of the ashbin refuse and street sweepings in large towns has been a source of considerable trouble and expense to the local authorities, and several vestries in London are now paying 3s. per ton for its disposal, exclusive of the expense of collecting it. Consequently, if 70 per cent. can be utilised and barging saved, considerable economy must ensue. There appears at the present time no doubt whatever that ordinary ashbin and street refuse should be dealt with by fire at the earliest moment and at the nearest possible point, as it soon becomes a prolific source of zymotic diseases. Consequently, prompt and localised destruction is particularly desirable, as railway conveyance or barging causes delay and contamination to the surrounding atmosphere.

Component parts.	Average per 1,000 loads. tons.	cwt.	qrs.	lbs.	Weight per cent.
Breeze, cinder, and ashes	611	3	0	4	63·69
Fine dust	187	1	0	8	19·51
Vegetable, animal, and various mineral matters	44	3	3	20	4·61

					100·00

In order to better understand what ashbin contents consists of the author appends the analysis of Mr. Joseph Russell, given in a paper read before the Sanitary Institute on February 10, 1892, and which may be of interest, the same having been practically corroborated by several other authorities.

From the report of the London County Council on dust destructors, the average from several districts gives 260 tons per annum for 1,000 of the population, although the actual quantities vary widely. Taking this into consideration, and the fact of the preponderant amount of combustible material which it will be noticed is present in this refuse, it is apparent that it should be disposed of by fire, not merely with a view to its destruction for hygienic reasons, nor yet to reduce its bulk (which is done by the destructors in present use, leaving only from 25 per cent. to 30 per cent. of ash and clinkers), but that the heat set free in the process of destruction should be utilised.

Prof. Forbes and others have estimated the value of ashbin refuse at a much higher figure than results from practice, the various estimates ranging from 3lb. to 5lb. of water evaporated for 1lb. of refuse. Hitherto, in practice, this result has not been obtained, and according to statistics collected by Mr. C. Jones, M.I.C.E., from the larger towns using destructors with steam generators by the waste heat, 6 h.p. per cell burning from six to eight tons every 24 hours appears to be the average result. This result, doubtless, can be increased by the use of forced draught, at the same time enabling the furnaces to do a far greater amount of work as destructors.

These statistics no doubt include the disposal of the street sweepings, which must be taken carefully into account, they being the vehicle for moisture impregnated with effluvia, which during destruction absorbs some of the active heat from the more combustible ashbin refuse. As the various local authorities, particularly around London, are now anxious to use their powers under the electric lighting provisional orders granted to them for laying down plant for lighting their districts by electricity, this appears to be the better and most direct method of using this source of gratuitous heat. At the same time there are waterworks and sewage pumping stations requiring steam, as well as baths and wash-houses, which frequently belong to the local authorities, where the heat could be advantageously utilised.

There can be no doubt that the calorific value of the refuse is low, particularly when street sludge is used, and from results obtained by the author only 1lb. of water evaporated per pound of unsifted refuse is actually obtained. With screened refuse, however—that is, with the paper and loose rubbish, commonly called breeze, taken out—a fair average of 2½lb. of water evaporated per pound of breeze is the result. For some months past the author has been using this fuel in an ordinary double-flued Galloway boiler 22ft. long, 7ft. diameter, with 22 cross-tubes and steam-jet forced draught, the boiler being used for boiling purposes. These results could only be obtained by burning the breeze in direct contact with the boiler, and could not be so obtained if used in a destructor and then passed through brick flues to the boilers. Mr. Jones's statistics, before referred to, are based upon the working of plants of the latter description.

The trouble in stoking owing to the amount of ashes and clinkers prohibits the general use of town refuse in boiler furnaces to any great extent. A very large boiler capacity and grate area, proportionate to the quantity of steam required, are necessary, far beyond that usually required for ordinary coal burning, and, further, unless the refuse is mixed with coal, 60lb. appears to be the maximum boiler pressure obtainable. Even with a strong forced draught in the ashpit 80lb. only has been obtained. Consequently, to make the use of the town refuse economical in connection with the best modern steam-engine practice, a greater heat must be available and a higher pressure attained. Moreover, in thickly-populated districts all escaping vapours must be rendered innocuous, so that there are three conditions for consideration—namely: (1) facilities for stoking and cleaning the fires; (2) burning up the obnoxious fumes; (3) temperature of combustion to be raised to produce higher pressures.

First, as regards facilities for stoking and cleaning the fires. The principle of the ordinary dust destructor in its general design is doubtless the best—viz., having the feeding hopper at the upper end and the firebars at a lower level continuing towards the cleaning doors, and having mechanically-moved firebars bringing the refuse forward, allowing the green fuel to be gradually brought towards the fire, thus evaporating and burning up the moisture in it. Of the several designs of different makers, that known as Healey's appears to be a good type, and most advantageous when used with a forced air draught, although there are several other designs which are equally applicable—viz., Fryer's, Horsfall's, Whiley's, and Warner's.

In Healey's furnace the hearth-plate is at an upper level on which the refuse is fed, and which in its descent travels on to a movable gridiron and from thence to the firebars proper. In order to keep the furnace at its full work this continual feed is necessary; but Healey's movement of the furnace bars has the triple effect of feeding the furnace and clearing the clinkers off the bars and pushing them into a receptacle for removal. This is accomplished by resting the front of the firebars on the dead plate, the back bearer being a rotating camshaft with eccentrics, on which is fitted each alternate bar which has a slot fitting these eccentric cams on their undersides. The other alternate bars are fixed to a bearer and in a recess on the front dead plate. On their upper edge another bar is fitted with a parallel ball and socket joint. The upper ends of these bars oscillate in a recess in the upper hearth-plate. The fronts of the firebars also oscillate on the front dead plate, so that on the bearer shaft being rotated towards the front the movable bars lift the clinkers and fuel forward off the fixed bars and a constantly clean fire is kept. At the same time new fuel is fed from the upper hearth-plate. The shaft is rotated by a ratchet wheel worked by an eccentric from a rotating shaft at the furnace front driven by the forced draught blast-engine. The air blast is brought from a conduit under the ashpits by pipes on either side and opposite each other in the fore part of the ashpits. Special facilities are provided for clearing away the dust from the flues at all possible points, and a dust-settling flue or chamber is also provided between the furnaces and the chimney, which is preferably on the back of the furnaces.

Hitherto the practice as regards the generation of steam has been to place a tubulous steam-boiler between the destructors and the chimney, leaving the walls of the flues to absorb a large quantity of the heat before reaching the boiler. Between the destructor and the boiler a Jones's fume cremator is frequently used, which consists of coke furnaces so constructed and arranged that the flues from the destructors conduct the gases over these fires by deflecting masonry, thus cremating them and rendering them innocuous by destroying the excess of moisture and effluvia which would otherwise escape as noxious vapours and condense in the atmosphere and cause what has been recently described as an unmitigated nuisance.

At Cambridge, Messrs. Wood and Brodie's system of furnace is being adopted. It consists of a water-tube, Babcock type steam generator placed in series between every two refuse furnaces. The waste gases are conducted through brick flues into a chamber under a V-shaped ash tray or pit, and then over its upper edges through the fire grate to the water-tubes and ordinary setting of the generators.

At Warrington, a special refuse furnace has been erected in front of the furnace of a Babcock steam generator, the place of which it takes. It is fitted with forced draught, the refuse fuel being conducted by hoppers from the floor above to the furnace. The following are the results of working which Messrs. Babcock and Wilcox have kindly supplied:

TEST OF PATENT DESTRUCTOR FURNACE WITH UNSCREENED REFUSE.—WARRINGTON INSTALLATION.

Date, noon to noon	November 23-24, 1893.
Duration of trial	24 hours.
Nature of fuel	unscreened refuse.

* Paper read before the Society of Engineers.

Digitized by Google

Total quantity of fuel burned	53,536lb.
Quantity of fuel per hour	2,231lb.
Total quantity of water evaporated	61,344lb.
Quantity of water per hour	2,556lb.
Weight of clinker produced	14,460lb.
Per cent. of clinker	27
Pressure of steam maintained	66lb.
Temperature of air in boiler-house	45deg. F.
Temperature of feed water	104deg. F.
Temperature of gases leaving damper	550deg. F.
Quantity of water evaporated per pound of house refuse	1·14lb.
Average temperature of copper-wire test	2,000deg. F.
Average air pressure (water) maintained	3½.
Draught velocity in feet per minute	820ft.

From the author's experience the system which recommends itself is that of placing a steam generator directly over the destructor furnace, so that the heat shall pass around or impinge directly on the heating surface of the generator. The ordinary generator furnaces are placed above the refuse furnace, and are used as supplementary furnaces to increase the temperature necessary for the higher pressure demanded, and also to cremate any obnoxious gases from the refuse furnace below. Where destructors are in use, and it is desired to utilise the heat from them to generate steam at high pressures, the generators may be arranged in a series adjoining the main flue to the chimney, and by connections the gases may be directed into their combustion-chambers, and so utilised and cremated. Where it is practicable, however, to place the generators over the existing lower furnaces or destructors, it is greatly to be preferred, as being more effective.

There is no doubt that the gases from refuse are impregnated with a large percentage of moisture, and are of low temperature. This is shown by an analysis of the gases, where a preponderating amount of nitrogen is found, amounting to 22 per cent., and any contact with the side walls of brick flues has the effect of impairing the efficiency, the walls being always ready to absorb some of the moist heat, the surfaces necessarily having to be large. With these considerations it will be seen that to obtain the best effect the radiated heat must be absorbed directly by and transmitted to the generator. This is accomplished by placing a reverberatory perforated firebrick arch over the refuse furnace, with the generator above it, so that when an excess of green fuel comes down from the hearth-plate, the regenerative heat from the arch assists to cremate the fumes before passing to the upper furnace.

There is no doubt that hand sorting of dustbin refuse will be largely discontinued on account of its degrading nature, and also from the decreasing prices of bones, rags, waste paper, etc., making it less profitable than formerly. There will, therefore, be a proportionately greater quantity of animal matter to be disposed of, and the consequent effluvia must be constantly dealt with, so that the need of an effectual fume cremator is absolutely necessary. These fumes it is proposed to cremate and destroy, with the assistance of the reverberatory arch, by the higher temperature of the combustion-chambers of the ordinary and supplemental furnaces of the generators, this being their hottest part, the temperature of which will be never less than 1,500deg. F. It has been found that to effectually destroy refuse fumes, 1,250deg. F. is absolutely necessary, and it would appear almost impossible for any effluvia to escape after passing through these two heats. Means must also be provided for the admission of fresh oxygen into the combustion-chambers if necessary to complete combustion; the gases or fumes from the destructors might also be burnt through the furnace bars of the supplementary furnaces, if desired, when oil or producer gas is used as fuel.

The author has recently had some experience of the effect of escaping effluvia when saturated with moisture. It was proved in a recent law case that persons in close proximity to the 60ft. chimney shaft from whence it was alleged the foul gases were escaping scarcely complained, but numerous complaints arose from those from 300 to 1,000 yards distant, showing that it took that distance to bring the saturated effluvia to earth.

In some existing plants in which no utilisation is attempted, the cost of fuel for the crematory fires has been so great that they have been discontinued, but serious complaints from the neighbourhoods are now arising, thus showing the advantages of cremation.

The calorific value of refuse being low, it is necessary to provide ordinary generator furnaces to assist in raising the steam to the required pressure for economical use as well as for cremating, as in several of the existing plants with the boilers in the flues 40lb. pressure per square inch is all that can be obtained, and at Warrington, as previously stated, 66lb. only is obtained even with forced draught. In the ordinary furnaces of the generator good fuel should be used, and if a supply of Russian oil can be obtained, that, or producer gas, appears to be especially applicable.

Having now described the general principles of the generation and absorption of the heat by the generator, and having specially in view the use of the steam generated by it for electric light stations—viz., to assimilate the supply to the demand—the author will deal with the question from the latter point of view. It is well known that the demand of electricity during the day is so light, even where a fairly high load-factor is obtained, that the use of the steam generating plant at even half its capacity would be an excess, so that a system of heat storage is necessary for the economical use of the refuse, as the destructors must always be at work. Any ordinary form of steam generator may be adopted, but the cylindrical dry-back marine boiler with two flues or the inclined water-tube boiler of the Babcock and Wilcox type are best suited. Lancashire boilers, on account of their length, are not well suited to the present purpose, as the temperature of the gases in the combustion-chambers frequently falls below 1,250 F., and allows the moisture to pass away undecomposed.

In all cases the refuse gases are conducted into the combustion-chambers or their hottest part, while in the marine form they are led to the space above the flues and opposite the tubes, the gases from the ordinary and crematory furnaces of higher temperature mixing with them. In the water-tube generators they enter the ordinary furnace from behind the furnace back, in both cases meeting with the partly incandescent firebrick masonry, which assists in evaporating any moisture and destroying the effluvia. It is also necessary to keep the generators short, otherwise the feeding floors must be placed over the boilers with descending hoppers. This design also takes up more ground area for the inclined roadway, the other forms being conspicuous for the small space occupied by them.

Referring to the refuse destructor and steam generator combined for dealing with 420 tons of refuse per week (which is an average quantity from several London vestries), some six or eight sets would be required for electric lighting purposes. These would be in one battery, adjoining each other, the flues between the arches over the refuse furnaces, and under the generators, would communicate with each other, so that any number of refuse furnaces might be coupled to one generator and its crematory furnace. For the day load, however, they should be worked in sets of three, so that the middle generator alone would have its ordinary furnace in use, the refuse furnaces below all communicating with the one generator by dampers being opened between them, and other dampers closing the two outer generators from the chimney flue. It will thus be seen that the two outer generators would be kept at the same working pressure as the middle one, and would always be available by their own furnaces being brought into use, so that the stand-by losses would be wholly taken up by the refuse. There would also be an excess of steam, during the extreme light loads, which should be stored in the following manner:

A tank or reservoir properly clothed to prevent radiation is to be placed as a roof to the boiler-house, and in this tank near the bottom is fitted a coil of pipes. The waste steam would be taken into this coil, which is immersed in water, thus condensing the steam, and ejecting the condensed water into the tank itself, eventually filling it with practically distilled hot water every day, and this would be the case either with condensing or non-condensing engines; but when condensing engines are used it will be preferable to filter the condensed water from the air-pumps, and use this as feed water through the boilers, and thence into the storage tanks, as before described, but where non-condensing engines are used it would be better to allow the exhaust steam in the coil to heat up and boil the water in the storage tanks, in which would be deposited most of the impurities, the coil being connected by a system of steam flow and water return to the generators. Under these circumstances a live steam feed-water heater and separator would be necessary to feed the generators during the light load, bringing into use the boiled storage water during the heavy demand for steam. When multitubular generators are used, care must be taken that increased internal tube area is afforded for the passing of the gases from the three refuse and crematory furnaces. This system can be applied to existing destructors, as water-tube generators may be made of a width to suit such circumstances where probably cylindrical boilers could not be so placed.

The net result of this system would probably be that ¾lb. of water would be evaporated by 1lb. of refuse, allowing for the lesser value of street sweepings or sludge and the absorption of a certain quantity of heat in the furnace masonry, as compared with the 1lb. of water per 1lb. of refuse, which has actually been accomplished, as before explained—a result which is corroborated by Mr. A. Collins, A.M.I.C.E., of Reading, and the Warrington tests in directly fired generators. Reducing this to financial terms, the saving in barging, which has been mentioned as the only credit, must be first considered. This, according to the average cost per ton to several of the London vestries, amounts to 3s. per ton after collection, and 70 per cent. can be utilised, leaving only 30 per cent. of ash and clinkers as a residue to be disposed of, which in the spring is readily marketable for roadmaking, and where crushing machinery is in use it can be prepared for mortar, and with cement manufactured into street paving. This source of profit will, however, be absorbed by the cartage on the unsold residue, also by the fuel account for the generator furnaces, for working the forced draught, and moving the furnace bars, the net saving being therefore the cost of barging or disposal of 70 per cent. at 3s. per ton; and taking six furnaces burning 10 tons each every 24 hours, equal to the consumption of 420 tons per week of seven days, 294 tons at 3s. will represent the saving in barging, amounting to £44 per week, or £2,288 per annum.

The gross credit will be the value of the steam generated from the refuse. As each furnace will be of a capacity to burn 10 tons every 24 hours, and taking 20lb. of steam per indicated horse-power per hour and non-condensing engines without the cremating fires, the effective evaporation will be equal to 35 i.h.p. per hour per generator set and available for electric lighting.

From the returns of the various London electric lighting plants published in *Lightning*, 1d. per unit appears to be a fair average for the cost of coal. Six destructors and generators would give an hourly output of 210 i.h.p. from refuse only, or, allowing 15 per cent. for frictional loss = 177 e.h.p., which at 1·34 h.p. per unit = 128 units at 1d., or 11s. 1d. per hour, say £93. 1s. 6d. per week, against which the extra cost of maintenance, wear, and tear have to be debited. If ashbin refuse alone were burnt the results would be 15 to 20 per cent. in excess of this, but this result could only be attained if the steam were used by the engine as generated, but against this, and as a general debit, the inherent losses of storing the heat and the reheating will have to be considered. As this process will be going on for two-thirds of each 24 hours, the author estimates this loss at 30 per cent., but being 16 hours only out of the 24 = 20 per cent. on the total 35 i.h.p., leaving a net effective result (after deducting 15 per cent. for frictional losses) of 23·6 e.h.p. per hour per set, which may be absolutely depended upon. The total value at 1·34 h.p.

Digitized by Google

per unit equals 1s. 5½d. per hour per set, or 8s. 9d. per hour for the six sets—that is

£73. 10s. per week, or, per annum ...	£3,822
Less £350 for steam for auxiliary blast and grate,engines and pumps	350
	£3,472

Mr. G. Watson, C.E., of Leeds, in his paper read before the British Association in 1892, gives the theoretical value of ashbin refuse as 11lb. evaporating 2·13lb. of water, and the practical result at 1d. per indicated horse-power per hour with a steam generating plant of improved type, or 1s. 3d. per cell per hour, burning 5cwt. of refuse at a total cost of 1s. 10d. per ton. At Oldham some authorities give the cost at 1s. 6d. per ton, including all expenses and depreciation. Taking these figures and the evaporative tests of the author, of Mr. Collins, and those from Warrington, the foregoing figures may be considered fairly substantiated, together with the results deducible therefrom. The ordinary or supplementary furnace heat is not considered in these estimates, as that would be directly available for extra evaporation at proportionately increased returns.

The author considers, as previously stated, that plant capable of dealing with 420 tons of refuse per week would be of suitable working capacity for a London vestry. The plant would consist of eight refuse furnaces (two in reserve), with six steam generators for 140lb. working pressure, with feeding, coal, and cleaning floors, forced draught, machinery, movable firebars, storage tanks, and chimney, and capable of a total output of 900 brake or electrical horse-power when fully loaded. The author estimates the cost, including £3,000 for the site, at £18,000. The maximum indicated horse-power from the refuse only is computed at 48 h.p. per cell, the extra evaporation by the supplementary furnaces at high load utilising the remainder of the heated feed water out of a total of 25,000 gallons. The following is a statement of the returns, which are inclusive of engineers' charges and royalties.

Wages, renewals, repairs, oil, lighting, depreciation, water, etc., at the Oldham estimates of 1s. 10d. per ton	£2,002
Yearly payment for redemption in 25 years of interest at 3½ per cent. and principal on a loan of £18,000	1,092
Credit balance.....	378
	£3,472
Value of heat	£3,472
From heat account	378
From saving in barging.....	2,288
Net saving	£2,666

The quality of ashbin refuse varies greatly. During the summer it is generally very poor, but from the better districts of London it may be advisable to sift it over a shoot during early spring, reserving the better fuel which it will be found to contain for use in the ordinary furnaces during the summer, and thus increasing the economy. From enquiries the author finds that the refuse from some localities would not repay this necessary outlay. The author's experience is that the Paddington siftings have been fully 25 per cent. less in value in July than in March, which has caused a lower evaporative average value to be given than the individual tests before referred to by others, as on individual weeks in January to March the breeze was particularly good, which is shown by the water and quantity tests.

The author has endeavoured to place the complex question of the disposal of town refuse in a practical light before the society. The obtaining of the facts has been the outcome of the necessity of obtaining a cheap fuel for slow steaming, and of utilising refuse for producing electricity. The author's experience in connection with electric lighting since 1878, particularly when required for factories, is that would-be users first ask themselves, "Have I engine or boiler power to spare?" The idea of a separate plant using a waste product has been, until the past few years, quite foreign to the question. It now, however, may be said to solve an important problem. It will probably be admitted from what has been stated that, in addition to meeting sanitary and hygienic requirements, this system of refuse utilisation constitutes a valuable source of profit, to which public authorities are at length becoming alive.

THE ELECTRICAL STANDARDS COMMITTEE.

FINAL REPORT.

In our issue of August 31 we reproduced an order by the Queen in Council describing the new standards of electrical measurements for use in trade. There has now been published, as a parliamentary paper, a supplementary report and final report of the Electrical Standards Committee. The supplementary report deals with the work of the committee down to the close of 1892. From the final report we extract the following:

To the Right Honourable James Bryce, M.P., President of the Board of Trade.

Since the date of our last report the Board of Trade have laid before us a *résumé* of the action of the International Electrical Congress held in Chicago in August, 1893, to determine the units of electrical measurement. We were also informed by the Board of Trade that her Majesty's Government had been invited by the United States Ambassador in London to take steps to adopt the recommendations of the congress.

These recommendations, so far as they refer to the units of electrical resistance, electrical current, and electrical pressure, are substantially the same as those suggested for adoption in our previous reports.

We see no reason for further delay in the legalisation of standards of the above-mentioned units, and we have prepared and attach a revised draft order in Council which we advise may be submitted for her Majesty's gracious approval.

The accompanying notes to the specification for the Clark's cell have been communicated by Mr. Glazebrook, and will be found of great assistance in the preparation of this form of cell.—(Signed) COURTENAY BOYLE, KELVIN, FRANCIS J. S. HOPWOOD, P. CARDEW, W. H. PREECE, RAYLEIGH, G. CAREY FOSTER, R. T. GLAZEBROOK, J. HOPKINSON, W. E. AYRTON, T. W. P. BLOMEFIELD (secretary), August 2, 1894.

NOTES TO THE SPECIFICATION ON THE PREPARATION OF THE CLARK CELL.*

The Mercurous Sulphate.—The treatment of the mercurous sulphate has for its object the removal of any mercuric sulphate which is often present as an impurity. Mercuric sulphate decomposes in the presence of water into an acid and a basic sulphate. The latter is a yellow substance—turpeth mineral—practically insoluble in water; its presence at any rate in moderate quantities has no effect on the cell. If, however, it is formed, the acid sulphate is formed also. This is soluble in water, and the acid produced affects the E.M.F. The object of the washings is to dissolve and removed this acid sulphate, and for this purpose the three washings described in the specification will in nearly all cases suffice. If, however, a great deal of the turpeth mineral is formed it shows that there is a great deal of the acid sulphate present, and it will then be wiser to obtain a fresh sample of mercurous sulphate rather than to try by repeated washings to get rid of all the acid. The free mercury helps in the process of removing the acid, for the acid mercuric sulphate attacks it, forming mercurous sulphate and acid, which is washed away. Pure mercurous sulphate when quite free from acid shows on repeated washing a faint primrose tinge which is due to the formation of a basic mercurous salt, and is distinct from the turpeth mineral or basic mercuric sulphate. The appearance of this primrose tint may be taken as an indication of the fact that all the acid has been removed, and the washing may with advantage be continued until this primrose tint appears. Should large quantities of this basic mercurous salt be formed, the sulphate should be treated as described in the instructions for setting up Clark cells issued from the Physical Technical Institute of Berlin (*Zeitschrift für Instrumentenkunde*, 1893, Heft 5).

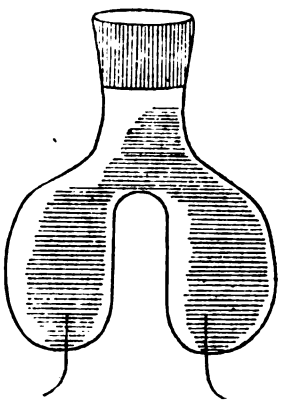
The Zinc Sulphate Solution.—The object to be attained is the preparation of a neutral solution of pure zinc sulphate saturated with $ZnSO_4 7H_2O$. At temperatures above 30deg. C. the zinc sulphate may crystallise out in another form; to avoid this, 30deg. C. should be the upper limit of temperature. At this temperature water will dissolve about 1·9 times its weight of the crystals. If any of the crystals put in remain undissolved, they will be removed by the filtration. The zinc sulphate should be free from iron, and should be tested before use with sulphocyanide of potassium to ascertain that this condition is satisfied. If an appreciable amount of iron is present it should be removed by the method given in the directions already quoted (*Zeitschrift für Instrumentenkunde*, 1893, Heft 5). The amount of zinc oxide required depends on the acidity of the solution, but 2 per cent. will in all cases which will arise in practice with reasonably good zinc sulphate be ample. Another rule would be to add the zinc oxide gradually until the solution became slightly milky. The solution when put into the cell should not contain any free oxide. If it does, then, when mixed with the mercurous sulphate, zinc sulphate and mercurous oxide are formed. The latter may be deposited on the zinc and affect the E.M.F. of the cell. The difficulty is avoided by adding, as described, about 12 per cent. of mercurous sulphate before filtration. This is more than sufficient to combine with the whole of the zinc oxide originally put in if it all remains free. The mercurous oxide formed, together with any undissolved mercurous sulphate, is removed by the filtration.

The Mercurous Sulphate and Zinc Sulphate Paste.—Although, after the last washing of the mercurous sulphate, as much water as possible may have been drained off, sufficient water generally remains to necessitate the addition of a very considerable quantity of crystals of zinc sulphate from the stock bottle, in order to ensure saturation, when the washed mercurous sulphate is added to the zinc sulphate solution as described in No. 4 of Specification B appended to the order in Council. If the sides of the test-tube above the cork be soiled by the introduction of the paste, the marine glue does not adhere to the glass; the liquid in the cell rises by capillary action between the glue and the glass, and may damage the cell. The form of the vessel containing the cell may be varied. In the H form devised by Lord Rayleigh and modified by Dr. Kahle the zinc is replaced by an amalgam of zinc and mercury. The other materials should be prepared as already described. Contact is made with the amalgam in one leg of the cell and with the mercury in the other by means of platinum wires sealed through the glass. The amalgam consists of about 90 parts of pure mercury mixed with 10 parts of pure redistilled zinc. These are heated in a porcelain crucible to about 100deg. C., and gently

*The specification will be found in the *Electrical Engineer* of August 31, 1894.

Digitized by Google

stirred until the zinc is completely dissolved in the mercury. The amalgam is liquid while warm, and must be poured into the cell before it becomes solid on cooling. The vessel containing the element consists of two vertical tubes. These, as shown in the figure, are closed below and open above into a common neck, which can be closed by a ground stopper of glass. The two tubes should be 2cm. in diameter and 3cm. in length. The neck should be at least 1·5cm. in diameter and 2cm. long. A short length of platinum wire is sealed through the bottom of each tube. The end of the wire in one tube is covered by a small quantity of pure mercury, that in the other tube by the zinc mercury amalgam. Above the mercury a layer about 1cm. thick of the mercurous sulphate paste is placed; above this, and also above the amalgam, a layer also about 1cm. in thickness of zinc sulphate crystals, and the vessel is filled up with the saturated zinc sulphate solution. The zinc sulphate crystals are obtained by evaporating at a temperature of less than 30deg. C. some of the zinc sulphate solution prepared as in 4 of the specification. The stopper is then inserted, leaving a small air bubble above the liquid, and sealed on the outside with shellac dissolved in alcohol. The ends



of the platinum wires outside the cell form the two poles, and should be connected to suitable terminals.

The final report concludes with the order in Council published, as already stated, in the *Electrical Engineer* of August 31, 1894.

NEW AYRTON-MATHER GALVANOMETER.

About two years ago we described* an improved form of moving-coil or D'Arsonval galvanometer, which has since been widely used under the name of the Ayrton-Mather galvanometer. The principal feature is the adoption of a narrow coil of peculiar cross-section, enclosed in a tube and suspended freely between the poles of the permanent magnet by a phosphor-bronze torsion strip. In these instruments the working parts are enclosed in an outer tube, Fig. 1, so as to protect them and render them interchangeable. No cover is required in this form.

It has been thought, however, that for laboratory and test-room work, where compactness and portability are not the chief essentials, an instrument whose working parts were more accessible and open to view would be useful. It was considered desirable to retain the interchangeability of the working parts, so that aperiodic or ballistic coils of different resistances could be used in any instrument.

The manner in which this requirement has been met will be seen from Fig. 2. A brass base, with levelling screws and a circular level, carries a tripod on which a powerful permanent magnet is firmly clamped. An insulated socket, connected to one terminal, is fixed beneath the poles of the magnet, and carries a vertical brass tube, cut away in front for the greater part of its length. The suspension strip is fixed to a torsion-head in the upper part of the tube, but is not screwed to it directly; it first passes through a fine hole in a thin bronze spring, which yields when the instrument is set down roughly, and prevents breakage of the suspension. The lower end of the tube is fitted with an ebonite plug, through which a brass stud is screwed, whose lower end makes contact on an insulated spring attached to the remaining terminal. This stud is slotted at its upper end, and fitted with a collar and set-screw to close the slot; similar clamps, seen in Fig. 3, are provided at the extremities of the tube containing the moving coil. The suspension strip is clamped in the upper of these, and the lower grips one end of the light spiral of phosphor bronze, which connects it with the fixed stud. Thus the coil is put in circuit with the insulated terminals, and hangs with its centre of gravity accurately below the point of suspension; it can be suspended by those who would find a difficulty in soldering the connections, but soldered contacts on the coil tube may be provided for those who prefer the original arrangement.

To clamp the coil securely, a slot is cut in the brass tube, opposite the middle of the coil, in which two phosphor-bronze springs work; when drawn back they embrace the coil and hold it firmly to the brass tube, and when pushed forward they clear it so that it swings freely. The flexibility of the connections allows this motion of the coil and clamping does not alter the adjustments; any number of the brass suspension tubes may be fitted to one instrument, and slipping them in place makes the connections.

The cover is made in two parts, so that only the cap need be lifted off to get at the torsion-head and set the spot on the scale. Aperiodic coils are enclosed in tubes of fine silver, but ballistic coils are fixed in ivory tubes. The mirror is attached to a metal clip soldered to the prolongation of the tube.

FIG. 1.

FIG. 3.

The general adoption of the moving-coil galvanometer by electrical engineers is due to its quickness of action, aperiodicity or "dead-beatness," and the fact that it is unaffected by the magnetic disturbances which make the use of sensitive Thomson galvanometers in the works such a misery.

Owing to the comparative unsensitiveness of the early D'Arsonval galvanometers, there is an impression that they cannot be as sensitive as those with suspended magnets, but Prof. Ayrton and Mr. Mather in 1892 showed that their pattern was more sensitive than the best Thomson galvanometers, having regard to resistance and time of swing.

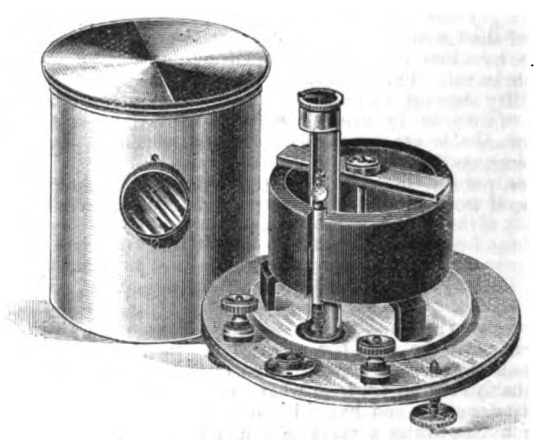


FIG. 2.

Great difficulties were, however, found to arise when the extreme sensitiveness sometimes required in the laboratory were attempted, though a good working instrument could be made to give 100mm. deflection with a millionth of an ampere. The difficulties were chiefly due to the traces of magnetism found to exist in the silk and other parts of the coil usually considered non-magnetic, and to the fatigue of elasticity or sub-permanent set of the fine suspension required in this case. A great number of trials was made at the Central Technical College, which showed that magnetism could be detected in almost all bodies by suspending them and noting the times of vibration within and without a magnetic field. The purest wire of electrolytic copper or of fine silver, specially drawn and covered, showed traces, and a method of treating the coils was at length devised which has practically solved this difficulty. The effect of "fatigue" of the suspension which causes the spot to come to rest slightly above zero may be reduced to a great extent by "ageing" the strip—*i.e.*, deflecting the coil, say, half-a-million times. By care in these details, and by proportioning the parts properly, the sensitiveness can now be pushed further than ever before without destroying the good working of the instrument, while the non-magnetic property of the coil allows a magnet to be used whose field is four times as strong as those originally used in this pattern. The instruments are made by Mr. Paul, of 44, Hatton-garden, E.C.

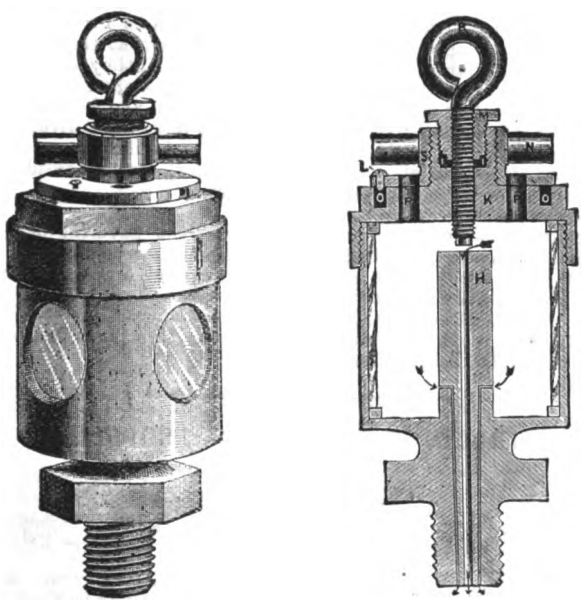
"SAFETY" AUTOMATIC DOUBLE-FEED CRANK-PIN LUBRICATOR.

In the accompanying illustrations is shown a lubricator now being introduced by Messrs. W. H. Willcox and Co., of 34 and 36, Southwark-street, S.E. This lubricator, the makers inform us, is the only lubricator specially made for the crank-pins of engines, pumps, etc.; all others up to the present time in use being make-shifts—such as syphon lubricators, needle lubricators, etc. It will be seen from the illustration that the feed of this lubricator can be regulated to suit the exact speed at which the crank is running, and by such regulation will only feed the absolutely necessary quantity of oil required; this is done by giving the piston, marked H, more or less play as necessary. There is no waste of oil through running away, when the crank is standing, as the piston comes down on to its seating, and thus closes the outlet.



There is no trouble in adjustment when once the screw is set, the refilling being done by turning the handle, N, to the left, and pouring the oil into the holes then opened on the top of the cover. To close this again it is simply necessary to turn this hard to the right, and the lubricator is then ready for use again. The body of the lubricator is of glass, enclosed in a strong gunmetal casing, by which means the quantity of oil can always be seen in the lubricator. The makers claim that for simplicity, safety, and reliability this lubricator stands out before all others, and as a result of its great efficiency and merits many of the largest engine-makers are now adopting it on traction engines, portable engines, fixed engines for electric light and other purposes, gas and oil engines, pumps, and all rods and cranks where there is any motion to keep it working.

ELECTRICITY IN CHELSEA.

We have received from Mr. T. W. E. Higgens, the surveyor to the Chelsea Vestry, his annual report, which, among other matter, contains the following information about the electric lighting of the district: The number of houses in Chelsea lighted by electricity by the various companies for the last three years was as follows:

	1891-2	1892-3	1893-4
Chelsea Electricity Supply Company ...	312	390	500
Cadogan Electric Light Company	18	—	—
London Electric Supply Corporation ...	2 (?)	—	6

It will thus be seen that the Chelsea Electricity Supply Company have maintained a steady progress, and appear to be giving satisfaction to their customers.

Meter Testing.—Under the Chelsea Electricity Company's order the Vestry, who are the electrical authority, are authorised to examine and test meters. Only one application was made during the past year to have a meter tested, which was from 59, Cadogan-square. Mr. Morgan Williams, A.M.I.C.E., tested it on behalf of the Vestry, and found that at the average load it registered 8·27 per cent. too low. The supply company on receiving this intimation fixed a new meter in place of the defective one. To avoid delay in the testing of meters the Vestry authorised the surveyor to make arrangements to have electric light meters tested immediately an application is received.

Extensions of Electric Mains.—The Chelsea Electricity Supply Company made application in April to lay mains in Redesdale-street, Tedworth-square, Christchurch-street, Oakley-street, Chelsea-embankment, Manresa-road, Elm Park Estate, and other streets in these neighbourhoods, and in December to lay mains in Wellington-square. The London Electric Supply Corporation gave notice of their intention to lay mains in Sloane-square and King's-road as far as Smith-street in May, but in October they extended as far as Flood-street.

St. Luke's Electric Lighting Order, 1891.—On June 9, the Board of Trade officially notified that they had revoked this order. The circumstances connected with the cancelling were detailed in the last annual report of the surveyor.

London Electric Supply Corporation.—In the early part of October, a slight accident, causing more alarm than damage, occurred on this company's circuit—namely, the blowing off the cover of a pavement box in Sloane-square. Major Cardew, on behalf of the Board of Trade, reported upon the accident, and recommended certain alterations in the circuit and the insertion of a more sensitive fuse. At the end of the year, however, the requisite alterations had not been carried out to the satisfaction of the Board of Trade.

Proposed Electric Lighting Scheme of the Kensington Vestry.—In November, the Kensington Vestry gave notice in the *London Gazette* of their intention to apply to Parliament for power to lay mains for electric lighting from their wharf in Lots-road through certain streets in Chelsea, so as to light a portion of South Kensington, and from their depôt in Kensal-road to light a portion of North Kensington. These notices, in the opinion of the surveyor, did not comply with the Electric Lighting Acts, and they were subsequently withdrawn, without the Bills being deposited.

Pressure Records.—Chelsea Electricity Supply Company.—From time to time the surveyor has examined the records of pressure kept by the Chelsea Electricity Supply Company. They still maintain a very good average where the records are taken at a pressure point in the mains. The automatic system of regulation adopted appears to be very satisfactory. Self-registering records of pressure are maintained at all the stations and sub-stations belonging to this company.

London Electric Supply Corporation.—After the explosion in the street box in Sloane-square, the Vestry authorised the surveyor to examine the records of the London Electric Supply Corporation. He finds that they have one record of pressure kept at Adelphi-terrace, which appears to be the only continuous record kept. The records are not so regular as those of the Chelsea Electricity Supply Company, but as the system of the London Company is, of course, a high-pressure system, it is, perhaps, not to be expected that there should be the same regularity as in a smaller low-pressure station. In the early part of December, owing to an accident to the machinery at the generating station at Deptford, the supply was cut off for a short time, which was also the case at the end of October, when the fault appeared in the mains at Sloane-square, but otherwise the supply appears to have been constant.

Town Hall Lighting.—During the year the Vestry had under consideration the adoption of electric light at the Town Hall and Council-chamber. Estimates were submitted by 13 firms, and varied from £225 to £500. The surveyor reported upon the four lowest estimates, and finally the Vestry undertook to adopt electricity in the Town Hall, Council-chamber, large room and corridors. At the end of the year the actual contract had not been entered into.

COMPANIES' MEETINGS.

BRUSH ELECTRICAL ENGINEERING COMPANY, LIMITED.

The fifth annual general meeting of this Company was held on Monday to receive the report of the directors and the accounts, which we published in our last issue. Mr. J. B. Braithwaite, jun., the chairman of the Company, occupied the chair.

The **Chairman** said that the past year with the Brush Company had been one of continuous employment in their factory, and one of great commercial prosperity, considering the very keen competition. The balance-sheet showed that there had been no change in the capital issued during the past year. There was a loan from bankers on security of £25,000. It might be asked how it was that they had arranged for this overdraft instead of issuing further capital, in view of the fact that the debenture stock and preference shares were at a premium. The answer to this was that they did not require any additional working capital; that the reasons which made it desirable to arrange for a temporary advance from their bankers were only of a temporary character—one, the increased overturn of business; another, the large amount of money they had locked up at the present moment in the retention fund on the municipal contracts that they were executing. In addition, they would see from the credit side of the balance-sheet that they held £43,000 in shares and debentures of other companies. It was probable that during the present year at least half would be realised and turned into money, which, they would see again, would enable them, by itself, to repay the loan to the bankers and have plenty of cash in hand. With regard to the closing of the Manchester and Cardiff stations, that was the fortune of war. In both those cases the Brush Company was the pioneer of electric lighting in those two cities. In Cardiff they had had an electric station for a considerable number of years, and the only trouble was that they did the work so well that the Corporation said: "This is too good a business; we will do it ourselves." So when they applied for the provisional order, thinking that having supplied the town for some years would give them a reasonable claim to it, they found that their supply had been so excellent, and had given such universal satisfaction, that they could not induce them to give the provisional order. The same thing occurred in Manchester. In the present state of the

Digitized by Google

electric industry there would be no occasion to go further in the way of pioneering and setting an example, for municipalities were convinced that it was to their interest to do the work themselves. In many cases they had come to the Brush Company as the people who were the most competent to supply them with first-class central-station plant. None of that plant, which was represented by £114,681 as in course of manufacture, was being manufactured for stock simply to keep the men employed and works going on. All of it was in execution of orders received. The net result, after paying interim dividend and charging interest on debenture stock, for the whole year was £15,938. 9s., out of which it was proposed that the sum of £12,150 be appropriated to paying the second half of the preference dividend, and a dividend on their ordinary shares at the rate of 5 per cent for the past half-year, carrying forward the balance, £3,788. Probably someone would ask why they did not pay the same dividend that was paid last year. It was quite true that they had earned it, but paying 7 per cent. instead of 5 per cent. would absorb £2,700. They could do that and still carry forward £1,088, and it was not unreasonable to ask if there was any special reason for not doing so. They had no special reason, except that the balance-sheets published by two competitors—the Electric Construction Company and Messrs. Cromptons—were of such a character that neither of them had earned their preference dividend out of trading profits, and it occurred to the directors that in an industrial company a carry forward of £800 or £1,000 was not sufficient. Turning to the profit and loss account, they would find that the gross profit this year had been £57,157, compared with a gross profit of £49,405, so that the gross profit had improved by £8 000. The standing charges had increased about 11 per cent., whilst the turnover had increased about 50 per cent. The business in Australia had been during the past year very much reduced and hampered owing to the crisis through which the Australian colonies had passed; but notwithstanding the financial depression the amount of debts that had been made was inside £50. With regard to the Vienna business, that had made exceedingly satisfactory progress during the past year. Turning to the accounts, there was a new item in their balance-sheet called "Trustees' Account," in connection with the employés' bonus scheme. With regard to the general prospects of the Company, it might interest the shareholders to know that during the year the stations which they had erected for the Municipalities of Lancaster, Huddersfield, and Hanley had been opened for work. They had also completed an installation for the Duke of Norfolk at Arundel Castle. They had now in hand the fitting up of a central station at Worcester, which was to be opened on the 11th of this month, and also works in hand for the Municipality of Leicester, which would be opened before the end of this year, and also for the Dover Company. With regard to the City of London contract, they were able to report satisfactory progress in regard to that from year to year. When they took that contract the largest size of dynamo machine made was one capable of giving 100 kilowatts, supplying 3,000 lights. The contract provided for their manufacturing machines of four times that size, and he was able to tell them at the meeting the year before last that they had successfully manufactured a machine of 200 kilowatts, which turned out to be capable of supplying, not 6,000 lights, but nearly 7,500. He was able to tell them last year that the two first of the larger machines had been built and erected in the City station These machines were specified to be capable of supplying 400 kilowatts, and they actually turned out machines capable of supplying 500 kilowatts—that was to say, each of those machines was capable of supplying current for 15,000 lights. Since last year they had erected four more machines of the same size, so that the City of London Electric Company had six of their 15,000-light machines over at its Bankside station, and its directors had ordered three additional ones. So far as the tests prescribed under specification had been carried out, in every instance the machinery supplied had exceeded the specification. The specification provided that the combined efficiency of the engine and dynamo should be not less than 80 per cent. The tests made by Profs. Kennedy and Thompson gave a result of 83 per cent. The specification also provided that the regulation test of the machinery should be 10 per cent., and the test came well within that figure. Credit was due to the technical officers by whom these results had been obtained. The engineer, Mr. Raworth, was responsible for the design of the engines, and the electrician, Mr. Mordey, was responsible for the design of the dynamos; and the fact that these gentlemen should have made designs of machines four times larger than they had ever built before, and that those machines should have been constructed from those designs practically without modification or alteration, was a very high testimony to the capability of those gentlemen. From the City Company they expected orders for another £100,000. As to the prospects of the County of London Company, he did not think it would be fair to say that they were one whit inferior to those of the City of London. The County of London Company held three very good London districts—St Luke's, Clerkenwell, and Wandsworth. In addition to that it held a very nice electric light station at Bournemouth, which already had nearly 18,000 lamps connected to its mains, and was earning a very satisfactory profit. Besides that it had a station at Dover which had a contract with the Corporation for the lighting of the town streets; also a contract with the pier company for the lighting of the pier, and also for lighting the harbour, besides the private lighting which it would get. In addition to that, the County of London Company had secured the outfall of Lake Windermere. Its directors would take the necessary steps for applying to Parliament for a provisional order, and if the scheme proposed should be carried out, they would be able to supply all the towns within a radius of 10 miles from their station at Newby Bridge. It would be one of the finest water-power stations that had ever been seen. In other directions the prospects of the Company were exceedingly good, and as they expected from them in the course of the next few years something like £1,000,000 worth of orders, they naturally felt a benevolent interest in their progress. Whilst it was impossible to prophesy what the financial result of the current year would be, so far as they had gone they had every reason to be satisfied. The works were at present employed to their utmost capacity, and orders were in hand which would keep them employed certainly up to the end of the present year, and additional orders continued to come in at a satisfactory rate. He moved that the report of the directors and statement of accounts to June 30, 1894, now presented to the shareholders be received, and that the same be adopted.

Mr. B. H. Van Tromp seconded the motion.

Mr. Boys said it should be borne in mind that for two years the ordinary shareholders received no dividend, and, while agreeing with the desire to have a reserve fund, he thought the ordinary shareholders might have been given 6 per cent.

The **Chairman** said there was no reason, in a sense, why they should not pay 7 per cent. on the ordinary shares for the past year, but he thought shareholders would agree that this was an opportunity for strengthening their position which they ought not to lose. His experience in industrial companies showed that a conservative policy was the best in the long run, and he thought that when people saw that this was a sound 5 per cent. dividend-paying company it would gain immensely in public favour, not only from an industrial standpoint, but from the lower consideration—the price of the shares on the market.

The motion was carried unanimously.

Resolutions were then passed confirming the payment of the interim dividends, and declaring the amounts recommended—namely, 6 per cent. on the preference shares and 5 per cent. on the ordinary for the six months ended June 30.

The retiring directors (Mr. A. H. Sanderson and Colonel F. G. Steuart) were re-elected, and Messrs. Cooper Bros. and Co. were reappointed the Company's auditors.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Manchester.—The Lancashire and Yorkshire Railway Company invite tenders by the 8th inst., for various stores, including copper and indiarubber.

Bradford.—Tenders are invited for the supply and erection of feed pumps and steam-pipes, for the Corporation. Copies of plans and specifications can be obtained at the Electrical Engineer's Office, Town Hall, on payment of £1. 1s., which sum will be returned on receipt of a bona fide tender. Sealed tenders, endorsed "Tender for Pumps," are to be forwarded to Mr. W. T. McGowen, town clerk, Town Hall, Bradford, by 15th inst.

RESULTS OF TENDERS.

Morley.—The Town Council have decided to buy an engine and dynamo from Messrs. Fowler and Co., of Leeds, for the purpose of lighting the Town Hall by electricity.

Cardiff.—For installing the electric light at the Town Hall and market buildings, for the Town Council, the tender of Messrs. Fergusson and Co., Cardiff, has been accepted at £523. 10s.

Kendal.—The Urban Sanitary Authority have accepted, for supplying and fixing telephonic communication between the gas company's offices, Parkside-road, and the borough treasurer's office, 69, Highgate, the tender of Mr. J. Tanner, 54, Stramongate, Kendal, at £21. 5s. Mr. W. Wilson, Entry-lane, Kendal, tendered at £21. 15s.

BUSINESS NOTES.

Southport.—An electricity class has been formed at the Science and Art Schools.

Hull.—Mr. Geo. B. Blanchard is to instal the electric light in the General Post Office.

Bedford.—Messrs. W. H. Allen and Co., of Lambeth, have erected new works here.

Killarney.—The lunatic asylum is to be lighted electrically by the Killarney Electric Light Company.

Basingstoke.—The Town Council have issued circulars to ascertain the probable demand for the electric light.

Southsea.—The residence of Captain Bradley, R.M., has been installed with the electric light by Messrs. Bowerman Bros.

Eastern Telegraph Company.—The receipts for the month of September were £57,368, as against £55,997 for the corresponding period.

Cuba Submarine Telegraph Company.—For the month of September the receipts were £186 less than for the corresponding period of last year.

Todmorden.—Messrs. Baxendale and Co. are carrying out electrical installations in Messrs. Bancroft and Co.'s Millsteads and Cinderhill Mills.

Direct Spanish Telegraph Company.—For the month of September the receipts were £1,898, as against £1,865 for the corresponding period.

Digitized by Google

Castleford (Yorkshire).—The matter of lighting the town by electricity is being left by the Local Board to be dealt with by the new District Council.

Eastern Extension Telegraph Company.—For the month of September the receipts show an increase of £839 as compared with the corresponding period.

Cheltenham.—Mrs. Wetherhed, the mayoress, will lay the memorial stone at the central electric supply station. The charge for current is to be 6d. per unit.

Croydon.—The General Purposes Committee of the County Council are considering the question of having all telegraph and telephone wires laid underground.

West India and Panama Telegraph Company.—For the two weeks ended September 30 the receipts show a decrease of £122 as compared with the corresponding period of last year.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending 30th ult. amounted to £988, as compared with £649 in the correspondingweek of last year.

Direct United States Cable Company.—A quarterly interim dividend of 2s. per share has been declared, payable on the 24th inst., being at the rate of 2 per cent. per annum for the quarter ended September 30.

Henley's Telegraph Works Company, Limited.—Warrants have been posted for a dividend on the preference shares of this Company for the half-year ending June 30, 1894, at the rate of 7 per cent. per annum.

Coventry.—The technical institute is to be lighted electrically by the Coventry Gas Fittings, Electrical, and Engineering Company, Limited, until such time as the Corporation are able to supply from their central station.

Bangor (Wales).—It is proposed to erect a pier and landing-stage at Garth Point. A tramway of 3ft. gauge will be fixed on the pier for carrying passengers' luggage and light merchandise. This tramway will probably be worked by electricity.

Sunderland.—The Museum and Library Committee have discussed the question of lighting certain portions of the building by electricity. Mr. Brown, the engineer, was in attendance, and was instructed to prepare an estimate of the cost, and furnish other information.

Capsule Battery Company, Limited.—This Company has been registered, with a capital of £30,000 in £1 shares, to acquire certain patents, patent rights, etc., for galvanic batteries, call bells, etc., and to develop and turn to account the same, as electrical and general engineers, metal founders, etc.

City and South London Railway.—The receipts of the Company for the week ended September 30 were £881, against £798 for the corresponding week of 1893, or an increase of £83. The total receipts for the current period of the present half-year amount to £11,118, as against £10,479 in the corresponding period of 1893, an increase of £639.

Cardiff.—The installation of the electric light in Cardiff is delayed through the lack of a sufficient supply of gunmetal tubing. Otherwise the work has advanced almost to completion, but through the delay consequent on the want of this material it will be probably from four to six weeks ere the streets will be lighted by the new illuminant.

Wells.—The Town Council have received an application from Mr. Dixon Browne for the consent of the Council to his application for a license to provide the city with electricity for lighting, and after a brief discussion it was resolved, on the casting vote of the Mayor, to refer the question of electric lighting to the Lighting Committee to consider and report to the Council.

Keighley.—A proposal was brought forward at Tuesday's meeting of the Town Council in favour of making application to the Board of Trade for a provisional order to supply electric light. The Gas Committee, however, who had brought forward the proposal, considered it rather premature, as only a few people had signified their desire to have the light. The matter was referred back to the committee.

Chelmsford.—Mr. Shepherd, the clerk to the Essex Provident Society, has complained to the Town Council of the dark state of the entrance to the Market-road from Duke-street, and it was agreed to place an incandescent electric lamp there. The Deputy Mayor complained of the delay in the lighting of Maltese-road, and suggested that Messrs. Crompton and Co. should be pressed to carry out the work at once. It was resolved to write a letter.

Aberystwith.—On Tuesday evening the Mayor and Corporation of Aberystwith inaugurated the installation of the electric lighting of the marine front and main portion of the town by a banquet. The marine esplanade is lighted by arc lights of 2,000 c.p., placed 45 yards apart, and similar lamps are placed in the main thoroughfares. The lighting is carried out by Messrs. Bourne and Grant, electrical engineers, of London, under a contract with the Corporation of Aberystwith.

Dublin.—The *Evening Telegraph* says: "The shareholders of the Alliance and Dublin Gas Consumers' Company had the pleasant fact before them at their half-yearly meeting that the profit for the half-year showed an increase of £12,000. This, representing as it does a great increase in the use of gas, is a remarkable fact side by side with the more extensive use of electricity as an illuminant." The South City Markets, which have been rebuilt, are lighted by means of six arc lamps.

Hereford.—Having received notice of intention of the Great Western Electric Light and Power Company to apply in the next session for a provisional order to supply electricity within this district, the Gas Committee on Tuesday recommended that it was desirable the Corporation should obtain such order under the Electric Lighting Acts of 1882 and 1888. The recommendation was referred by the Town Council to a committee for consideration, with power to call a special meeting of the Council.

Ealing.—Messrs Paterson and Cooper have wired and fitted the following buildings for the electric light, for the Ealing Local Board, under the specifications of Messrs Bramwell and Harris, the consulting engineers: the public offices, Victoria Hall, Princes' Hall, etc., public library and newsrooms, public baths, fire station, stables, hospital, mortuary, and laundry, and Woodlands-terrace and lecture hall. The current was supplied to these buildings on Wednesday. The firm have also carried out numerous other installations in this district in connection with the public supply.

Liverpool.—Mr. J. Miles presided at the weekly meeting of the Finance Committee of the Town Council. A letter was received from Councillor Meade-King suggesting that the electric light should be substituted for gas at St. George's Hall and the Municipal Buildings. The Finance Sub-Committee had considered the matter, and recommended that in view of the great improvements constantly being made in the electric light, it was not desirable to incur any large expenditure on the electric light at present. It was resolved to send a letter to Councillor Meade-King to that effect.

Aluminium Company, Limited.—The Oldbury trading account shows a profit of £19,456. 5s. 2d. for the financial year. After providing for debenture interest, amounting to £7 043, and other fixed charges, and allowing for depreciation on plant and buildings, there is a balance of £4,775. 6s. 2d. Out of this the directors recommend the payment of a dividend of 5 per cent. for the year on the A shares, which will absorb £3,000, leaving a balance of £1,775. 6s. 2d. to be carried forward, less the sum of £300 due to Mr. Castner, under his agreement with the Company. The electrolytic process adopted by the Company is turning out well.

Ealing Electrical Exhibition.—Messrs. Paterson and Cooper have wired the whole of the buildings for the temporary lighting of the electrical exhibition. A pretty effect has been obtained by the grouping of about 400 united incandescent lamps and artificial foliage in the entrance hall and staircases. Their exhibit is worthy of note, containing as it does some excellent examples of hammered iron, brass, and other artistic fittings for domestic lighting. This firm also exhibit several of their well-known measuring instruments, arc lamps, dynamos, and other specialities. A search-light projector, of the Suez Canal type, manufactured by them, is also shown, and is used with great effect on the forest scene at the back of the hall.

St. Helens.—The Electric Lighting Sub-Committee of the St. Helens Corporation have had under consideration the question of electric lighting in the borough, and the town clerk, who was instructed to arrange terms with Mr. R. Hammond for a report as to the adoption of a scheme for the supply of electricity, reported at a subsequent meeting that Mr. Hammond had agreed to make such a report for the inclusive fee of 50 guineas, such fee in the event of his being engaged as engineer for the carrying out of the scheme to merge into his charges, which would be 5 per cent on the cost of the work. Mr. Hammond has paid a visit to St. Helens and discussed with the committee the local circumstances, the probable demand for and the best means of providing electricity for the purposes of his report upon the matter.

Monmouth.—On Monday, at a meeting of the Corporation, the official seal was affixed to agreements with Messrs. Bramwell and Harris, C.E., and Mr. Charles N. Lailey, C.E., London, for preparing plans and specifications and superintending the work of a combined scheme of drainage and electric lighting in the borough at an estimated cost of £17,600—£12,000 for drainage and £5,600 for electric light. The Corporation are to pay the engineers 5 per cent. on the total outlay, find a clerk of works, pay for advertising and out-of-pocket expenses. Mr. Lailey is engaged for the sewerage scheme, and Messrs. Bramwell for the electric light and pumping sewage to the purifying station. Both engineers agree to make any alterations in the plans which the Local Government Board may require without any extra cost to the Corporation.

Woking.—The Sanitary and Lighting Committee of the Local Board have reported that Messrs. New and Mayne expected to be able to light the streets, according to their contract, on the 8th inst. Mr Storey said the Lighting Committee found it advisable to make certain alterations in the positions of some of the lamps. On the other side of the station some of the lights were taken away, as it was found that the road got a considerable amount of light from the station lamps. One or two double lamps had been replaced by single ones. The plan was before the Board, and he proposed that the positions of the lights should be modified accordingly. Mr. Wenham seconded the motion, which was agreed to. Mr. Storey then proposed that the expense of lighting the Woking Station and Maybury Ward should be charged to that ward, and this being seconded by Mr. Wenham was also carried.

The Mildé Telephones and Electric Supply Company, Limited.—This Company has been formed (1) with the object of acquiring the sole right granted to Mr. M. Kotyra by Messrs. Ch. Mildé Fils and Co., of Paris, to sell their improved telephones in Great Britain and Ireland and the English colonies, and also to purchase certain royalty rights granted to Mr. Kotyra by Messrs. Mildé Fils and Co.; (2) to establish, local, provincial, and private telephone exchanges for hotel services, central railways, ships, mines, factories, public and private offices, clubs, works, and private dwelling-houses; (3) to carry on other branches of electrical works, such as electric light signals, lightning conductors, bells, etc.; and (4) to supply and fix all the appliances and fittings

Digitized by Google

required in connection with telephones, and the distribution of electric current, whether for lighting or other purposes. The capital of the Company is £20,000 in 15,000 7 per cent. cumulative preference shares and 5,000 deferred shares of £1 each.

Redditch.—On Tuesday night Mr. Evans, at a meeting of the Local Board, read the report of the Electric Lighting Committee, who had engaged Mr. J. A. M'Mullen to prepare a scheme for and report upon the probable cost of lighting the town by electricity. Mr. M'Mullen had prepared two schemes. The first provided for lights amounting to 1,500 lamps at an estimated cost of £7,000 or £8,000; the other to provide 4,000 lamps at an estimated cost of £13,000 to £14,000. The committee found that by making a charge for the light equivalent to that now being paid for gas the first scheme would more than pay expenses, and that the second scheme, with charges on the same basis, would result in at least £1,200 per annum profit to the town. The committee suggested that as soon as promises for the adoption of from 1,500 to 2,000 lights had been obtained a provisional order should be applied for, but as the new Council would shortly be elected it would be advisable to postpone the decision.

Bristol.—The Lighting Committee reported on Monday to the Town Council that it was desirable in the interests of the citizens to adopt the electric light for the city, but that it should be carried out by the Urban Sanitary Authority, and that the town clerk should ascertain from other towns where similar works have been carried out the name of a competent engineer to advise the Authority, and report the same at the next meeting. After a long discussion, the recommendations of the committee were adopted. Messrs. Verrier's shops and warehouse have been fitted with 12 of Messrs. Johnson and Phillips's Brockie-Pell alternating-current arc lamps, each taking a current of 10 amperes, and burning for 10 hours before requiring to be recarboned. This is said to be the largest private arc lamp installation at present on the city supply mains. In connection with the Kingswood Electric Tramways, a gang of men employed by the tramways company commenced work on Monday in Bell-hill, St. George, pulling down a projecting house and excavating a high bank to widen the road preliminary to laying the rails. The narrowness of the road in many places between the present terminus of the St. George's line and Kingswood will necessitate many alterations of the existing street boundaries.

Aberdeen.—The city electrical engineer, Mr. E. T. Ruthven-Murray, has reported to a meeting of the Gas and Electric Lighting Committee of the Aberdeen Town Council that, in consequence of the large and increasing demand for electric energy, an extension of plant will be immediately required. He stated that there were now 80 consumers having in all 7,000 lamps connected to the mains. It will be remembered that the station was opened on February 28 last, and the fact that an extension is required in less than seven months shows with what popularity the light has been received. The progress of electric lighting in Aberdeen has been exceptionally rapid and successful. The supply was commenced at a most disadvantageous time, as the city is so far north that in summer there is practically no night. A large proportion of the load is shop-lighting, but it also includes three hotels, a few private houses, Robert Gordon's College, and the School of Art. The committee resolved that Prof. Kennedy should be requested to report as to what additional plant he would recommend should be provided. At Monday's meeting of the Town Council, the minutes of the Gas and Electric Lighting Committee stated that a letter had been submitted from Prof. Kennedy, in which he referred to the exceptionally rapid and successful progress in the demand for electric light, and stated that the limit of the capacity of the plant has been already reached. Prof. Kennedy further stated that although the plant was quite sufficient for present purposes, it would be necessary for the committee to consider the question of providing extended plant. Under the circumstances the committee resolved that Prof. Kennedy should be requested to report as to what additional plant he would recommend should be provided. This was agreed to.

Belfast.—An important change is about to take place in connection with the shipment of cattle to Belfast, and one which will give the greatest satisfaction to those in the trade. For some time past it has been in contemplation to commence the inspection of cattle by electric light, to obviate the inconvenience which arose from the enforcement of the order in Council, which prohibits the inspection of cattle after sunset. The Great Northern Railway Company have been the first to make a move in the matter, and they have now introduced the electric light at their cattle depôt. The installation and the arrangements made have been inspected by Mr. Prentiss, the travelling inspector of the Veterinary Department of the Privy Council, who arrived specially in Belfast for the purpose, and who was accompanied by Mr. Boal, the local portal inspector. It is understood that he was satisfied with the result of his inspection, and if the innovation meets with the approval of the Privy Council, and if it is calculated to prove the great advantage anticipated, no doubt the same mode of inspection will be adopted at the Belfast and Northern Counties and County Down Railway depôts, and at the cattle yard on the Lagan Bank-road. Alderman Pirrie has presented to the Town Council the report of the Electric Lighting Committee, which contained the following: "Your committee have to report that the time has now arrived to appoint an assistant to the resident engineer who will be capable of taking charge of the central station when Mr. M'Cowen is engaged on other duty, and they recommend that they be authorised to appoint a duly-qualified man at a salary of £120 a year." Councillor Andrews seconded the motion for the adoption of the report. Councillor W. M'Cormick said he supposed that the appointment would be made by the Council in committee. Alderman Pirrie said the committee would select five or six names, and leave it to the Council in committee to make the final appointment. The report was adopted.

Middleton.—A system of electric lighting is to be introduced at Middleton, near Leeds, which possesses novel features. Middleton is the property of the Middleton Estate and Colliery Company, Limited, and upon the estate are two mansions, a colliery, a village, having a population of 1,200, and provided with a church, schools, chapel, and workshops necessary for the maintenance of the colliery. The owners of the estate recently requested Mr. T. Harding Churton, electrical engineer, of Leeds, to prepare a scheme for lighting the greater part of the estate, including the mansions, church, schools, chapel, works, etc., by electricity, to be generated at the colliery, and the necessary work is now being carried out by Mr. Churton. A constant supply of electrical energy is to be developed at the colliery, the power being derived from a steam-engine, which is also used for ventilating the mine, and which has two cylinders of 24in. diameter and 6ft. stroke. The electrical plant will include an alternating-current dynamo capable of developing 20,000 watts when driven at a speed of 850 revolutions per minute, and is being constructed by Messrs. John Fowler and Co., Limited, of Leeds and London. A current of 20 amperes, at a pressure of 1,000 volts, will be available, and will be transmitted from the source of power to the several points at which it is to be utilised by means of an underground concentric cable, designed by Mr. Churton, and specially made for the purpose by Messrs. W. T. Glover and Co., of Salford and London. The length of this cable will be about 2,300 yards. Suitable transformers will be erected at each point where the cable is tapped, the pressure of the current in the buildings to be lighted being thereby reduced to 100 volts. In addition to the lighting above mentioned, a number of arc and incandescent lamps will be erected and installed at the colliery to light the colliery yard, buildings, and offices. It is expected that the work will be completed about the middle of November.

Battersea.—The special committee of the Vestry appointed to consider the question of electric lighting have presented a report. The committee had received letters from Mr. S. Morse, on behalf of the County of London and Brush Provincial Electric Lighting Company, Limited, and from the St. James's and Pall Mall Electric Light Company, Limited, enclosing notices of the intention of the companies to apply for provisional orders authorising them to supply electrical energy for public or private purposes within the parish of Battersea, and from Mr. A. J. Lawson, engineer and manager of the County of London and Brush Provincial Electric Lighting Company, Limited, relative to the application of the company for a provisional order, stating that the company had no desire whatever to use overhead conductors; that they intended themselves to carry out the undertaking under the powers of the provisional order; and that, if obtained, they had no intention of selling or otherwise dealing with such powers. The committee had also considered the reference of the letter from Mr. S. Morse, applying on behalf of the County of London and Brush Provincial Electric Lighting Company, Limited, for a right of way for the company's mains through the parish of Battersea, for the purpose of lighting the parish of Clapham from the central generating station in Wandsworth, the company having obtained a provisional order for electric lighting in the district of the Board of Works for the Wandsworth District. The committee were strongly of opinion that it would be most inadvisable to allow the powers of the Vestry to pass into the hands of a company. They were not, however, at present prepared to recommend the Vestry to take steps to obtain a provisional order for powers to light the parish by electricity, and the committee therefore recommended that the further consideration of the question be allowed to stand over for the present, and that Mr. Morse be informed that the Vestry intended to apply for a provisional order for lighting the parish with electricity, and that they could not grant the request contained in his letter. Mr. Willis presented the report, which was adopted.

Londonderry.—At Monday's meeting of the Lighting Committee of the Corporation the resident engineer (Mr. Christie) reported that since September 6 there had been 12 more breaks in the cable. Some of these had left 44 lamps in darkness on particular nights, and some of them a smaller number of lamps. In two or three instances the breaks had occurred during testing, but in the majority they had occurred during ordinary running. Councillor Thompson said in connection with the testing they would be astonished at the revelation he was about to make. Their engineer (Mr. Blake) drew up a specification, which was submitted to Dr. John Hopkinson, of London, for his approval. On Dr. Hopkinson approving of the specification tenders were invited. Messrs. Siemens Bros.' tender for the cables was accepted. A few days ago he asked regarding the tests that were to be given to the cables according to the specifications, and he was told that they had all been given. On making enquiry he got the original specification, sealed by Messrs. Siemens Bros., and he was astonished to find that the clause relating to the efficient test—the clause that was in the document submitted to Dr. Hopkinson and approved by him—had been struck out. In the document with which Messrs. Siemens accompanied the specification they said the tests as mentioned were impracticable. So far as he knew, it was not known by the Corporation when they accepted Messrs. Siemens's tender that it was minus the clause relating to the test. Alderman Bell said this was quite a revelation. The Mayor suggested the committee should adjourn and request the attendance of Mr. Blake. Councillor Turner said when he moved that the plant should be taken over from Messrs. Siemens he did so on the certificate that

Digitized by Google

the work had been done to Mr. Blake's entire satisfaction. He knew nothing of any modification of the specification. A long discussion ensued as to what was best to be done in the matter, and eventually a motion was carried that, considering the gravity of the matter referred to, the meeting adjourn, and that Mr. Blake be requested to attend the adjourned meeting. Mr. Christie, in his report, added that one of Messrs. Siemens's head electricians, who had been sent over to look into the cause of the repeated flaws in the cables, was in the station when one of the breaks took place. He had now returned to London to report to Messrs. Siemens.

Dalton.—The Highways and Lighting Committee of the Local Board reported as follows: "Electric lighting: Read letter of 29th ult. from the clerk to the Ulverston Union Rural Sanitary Authority in reference to notice by the Windermere and District Electricity Supply Company, Limited, of intention to apply to the Board of Trade for an order authorising the supply of electricity within the area of the jurisdiction of the Rural Sanitary Authority, and suggesting the appointment of a committee of the Board to confer with that and other local authorities with a view to combined opposition to the application. Resolved that a sub-committee, consisting of Messrs. Lawn, Walton, and Wardley, be appointed for the purpose." Mr. Walton moved the adoption of this report. Dr. Challinor asked what were the grounds on which the committee recommended the Board to join the opposition to the Windermere and District Electricity Supply Company, Limited? How would it affect the Board? The Board had an order which cost them some considerable sum of money. The Clerk: The powers have lapsed some time ago. Dr. Challinor was not aware of that. Mr. Dickinson asked whether they were to oppose some progressive steps in the district. Personally he should be sorry to oppose any new industry in the neighbourhood. There was a great water power in the neighbourhood of Backbarrow which, it was supposed, would be utilised. The Clerk said there was no resolution to oppose. The resolution was simply one by which they would be able to get information. The Chairman observed that it said "with a view to combined opposition." Mr. Wardley said, if he remembered rightly, the committee did hesitate in the first instance as to the appointment of the committee, but the clerk thought it would be better to appoint one if only for the purpose of gaining information respecting this matter. They evidently knew very little about it. Dr. Challinor thought if they passed the resolution as it stood it meant opposition to the scheme of the company. The Clerk: No. Mr. Wardley: There is no intention to oppose. The Chairman suggested that the latter part should be struck out of the report, which would then end with "to confer with that and other local authorities." Mr. Walton understood that the resolution was framed simply as a means of getting information. The Chairman remarked that the Board had not the faintest idea of raising opposition to any progressive step. The report was adopted.

Leeds.—Electric lighting is making considerable progress here. It was in May last year that the works of the Yorkshire House-to-House Electricity Company were formally opened. Their capacity then was 600 i.h.p. Between June and December the number of 8-c.p. lights connected increased from 7,000 to 10,637, and for a short time before Christmas the company was compelled to decline further applications, the producing power being fully taxed during the time technically termed the heaviest load. The number of 8-c.p. lights now connected is over 15,000, and the mains extend about eight miles. Additional plant has therefore very soon become necessary, and this is now being laid down at the company's station in Whitehall-road. The engine-house has been considerably extended. Originally it was 68ft. long by 63ft. wide. Now its length is 124ft. The new plant comprises three additional Lancashire boilers, each 30ft. by 8ft., and capable of working up to 140lb. pressure; three horizontal condensing engines, each of 400 i.h.p., and three 200-kilowatt alternating-current dynamos. With the 600 i.h.p. now in operation, the capacity is thus being raised to 1,800 i.h.p. The three new boilers have been fixed, and two of the new engines constructed, and the entire installation will be completed before long. The additional plant has, of course, necessitated an extension of the switchboard. Wherever there is a sufficient demand for the light to warrant an extension of the mains it is to be met. Low-tension distributing mains are being brought into use in districts where consumers are closely grouped, and these are expected to give increased economy in working and greater convenience in connecting new customers. Already the light is being supplied to a large number of the public buildings and business establishments in the city, and the company expect to be called upon to illuminate the Town Hall and Municipal Buildings, the Corporate Buildings Committee having decided to recommend an agreement being made for a two years' supply. Offers have also been made to the Corporation to supply current for street-lighting and for the illumination of City-square and the public markets, and these are under consideration. The directors are naturally desirous of obtaining a consumption which will keep the plant fully employed, and, with this end in view, they have decided to supply current for motors, cooking, and heating purposes at a reduced price. An electric oven in one of the clubs is said to be giving very satisfactory results. At Wednesday's meeting of the Town Council, Alderman Sir Edwin Gaunt moved, "That the Corporate Property Committee be authorised to arrange with the Yorkshire House-to-House Electricity Company for the supply of electric light for the Town Hall and Municipal Buildings for a period of two years." It was, he said, absolutely necessary that something should be done at the Municipal Buildings, for with the present arrangements they constituted a nuisance to neighbours and a danger to property, while bad smells were given off, and the vibration of the engines was objectionable. A report had been furnished to the committee by the chairman of the Corporate Buildings Committee and the city engineer, which showed that the cost at present was 6·70d. per unit, while if they took it from the House-to-House Company the cost would only be 6·57d. per unit. There had been some talk of establishing a plant at Kidacre-street destructor, but that would involve an outlay of £11,300, and the cost of production would amount to 7·21d. per unit. They had spent a lot of money already, but he did not think that they had yet got a proper system. If they got the work done by the House-to-House Company for two years, they would be able to tell at the end of that time whether it would be profitable to carry on the installation themselves or not. The resolution was carried.

Worcester.—The sub-committee of the Watch Committee have recommended that the charge for electricity for motive power be 3d. per unit, and that a separate meter be used. The Mayor remarked that this was an inducement to manufacturers and others to take the current, which would be supplied by the day's load. They could afford to supply the current at 3d. per unit during the daytime. The price proposed to be charged was equal to 1s. 6d. per 1,000ft. for gas, so that any man who used electricity at 3d. per unit would be far better off than by using gas. The Sheriff: It does not require the attention or the space. The recommendation was adopted on the proposition of Alderman Hill. On the recommendation of the sub-committee, it was decided to extend the electric mains to comply with applications in College-street and Sidbury to the house of Dr. Walpole Simmons at an estimated cost of £35, and in Friar-street to the house of Mr. Andrews; also along Bransford-road, which, with the erection of the oil-tower in the Bull Ring, St. John's, will cost £210. Mr. Preece reported that he had temporarily engaged two engine-drivers, two dynamo men, two stokers, one trimmer, and two linemen to take over the working of the generating station at Powick on October 11. The committee confirmed this. It was decided to affect an insurance with the Engine Boilers' and Employers' Liability Company, through Mr. A. P. Watkins, on the boilers at the generating station in the sum of £2,000, at an annual premium of £12, to cover damage to surrounding property. Mr. Winwood asked why Barbourne streets should not be lighted, as the mains were to go to the waterworks. The Town Clerk pointed out that there were different mains required for street and house lighting, and that another main would be required to light the streets at Barbourne. Mr. Chaplin remarked that it seemed to him a pity there should be so many separate applications. If they were to first lay down the mains through an important thoroughfare like Sidbury, they would get a lot of applications. The Mayor: All the citizens have to do is to apply, and they will get the light in due course. Mr. Davenport (Mr. Preece's representative) reported that the equivalent number of 8-c.p. lamps wired at present was 3,850, being equal to 400 h.p., and independent of the waterworks, pumping, and street-lighting. Several prominent places were being wired—viz., St. George's and St. Michael's Churches, the Union Club, Shire Hall, etc. Mr. Chaplin asked whether the application from Malvern was still under consideration. The Mayor replied in the affirmative, and said Mr. Preece would report upon it, but they did not expect to do anything more before October 11. There was a very great disposition on the part of prominent residents at Malvern to have the light, and if any solid move were made he thought the scheme would go well. Alderman Hill expressed the hope that the committee would see Worcester safe, and the arrangements here satisfactorily carried out before undertaking further work.

Folkestone.—The peculiar position of electric lighting schemes is shown by a long report of the proceedings of the Town Council on Wednesday of last week, published in the *Folkestone Herald* on Saturday. The position is summed up editorially by that paper as follows: "There is something of a comical side to the new attitude taken up by a majority of the Folkestone Corporation with regard to the introduction of electric lighting into this borough. The doings on Wednesday may fairly be said to have beaten the record. To understand them aright, it is necessary to give a *résumé* of the action hitherto taken on the subject of lighting the town, or a section of it, by means of electricity. For several years the most forward advocates of local improvement have been insisting that, until the electric light is installed amongst us, the town of Folkestone can only claim a subordinate position in the list of popular watering-places. Gradually, the inhabitants came over to that view. At length, however, it emerged into practical domain, and the Corporation found it expedient to humour the popular taste. A committee of enquiry was appointed, with instructions to take professional advice and to bring forward a scheme. Those instructions were acted upon, and a scheme was in due time formulated, which was said to secure all the advantages of the high and low tension distribution. We may say, in brief, that it was a £35,000 scheme; the various details of which could be reduced ratably if a smaller area were decided upon. It was claimed for this scheme that its producing capacity would be equal to any demand that might arise in the town for many years to come; and it was further contended that the cost of the working expenses would fluctuate in proportion to the demand for the new light. It is now a matter of local history that this important aspect of the question was almost completely ignored. The opposition to the scheme fastened itself to the outlay of £35,000, and the popular mind became alarmed at this expenditure. A most amusing incident occurred at this stage. The knot of so-called 'Reformers,' who had inscribed 'Electric Lighting' on their banner, turned

Digitized by Google

round and swallowed their own professions, giving the scheme the most determined opposition that it was possible for them to command. The scheme was thus rejected by the voice of a public meeting at the Town Hall, and that rejection had its natural effect within the Council-chamber. A smaller scheme, of some £12,000, was talked of as an alternative proposal, and was strongly championed by a member of the Corporation who had led the opposition to the original scheme. Such was the position of the question on Wednesday last, and on that occasion a new departure was resolved upon. During the interval the old scheme—that of £35,000—had remained in a state of suspended animation. It had not been formally rejected by the Corporation, nor had the Electric Lighting Committee been discharged from its original function. On Wednesday, with the old committee in existence, and the old scheme in a pigeon-hole, a motion was made and carried that a new committee be appointed to go into the matter, to employ another expert, and to present an alternative and entirely independent scheme involving a capital expenditure of some £12 000. This is the comical side to which we have referred above. The new committee does not include a solitary member of the old committee except the Mayor, who is *ex-officio* a member of every committee of the Corporation, at least in theory. Here, then, we have two rival committees appointed to deal with one question, each committee having its own electrician, and each empowered to expend 50 guineas on professional advice. This is a ludicrous situation, and is scarcely consonant with business habits and procedure. As to the remarks made, either on Wednesday or previously, against the professional status of either of the two experts, no sensible person will attach the slightest importance to them. They are utterly beside the mark. They can have no effect upon public opinion except to evoke a feeling of regret that two sections of a public body should be so wanting in taste as to identify professional men with their own quarrels. Nothing said on Wednesday in the Council-chamber can add to or detract from the reputation of Mr. Parker or Mr. Medhurst, and it was exceedingly indecorous to drag that element into the discussion."

PROVISIONAL PATENTS, 1894.

SEPTEMBER 25.

18153. **Improvements in electricity meters.** John Perry, 31, Brunswick-square, London.

18172. **Improvements in and apparatus for the extraction of gold by electrolysis.** Joseph John Maclean, 78, Fleet-street, London.

18177. **Improvements in electrically-actuated brakes and belt-shifting devices.** Paul Auguste-Godchaux, 6, Lord-street, Liverpool.

18188. **Improvements in and relating to electrical fittings.** Emil Hungerbühler and the Electrical Company, Limited, 151, Strand, London.

18196. **Improvements in current collectors for overhead electrical conductors.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Messrs. Siemens and Halske, Germany.)

18202. **Improvements in and connected with primary batteries.** Howard Vivian Coad, 37, Cursitor-street, Chancery-lane, London.

18206. **Improvements in utilising residual products obtained in working certain kinds of voltaic batteries.** William Walker, jun., and Frank Richard Wilkins, 7, Staple-inn, London.

18217. **Improvements relating to the transmission of telephonic messages between the shore and a lighthouse, ship, or other signal station.** Lucien Ira Blake, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

SEPTEMBER 26.

18273. **Improvements in electric motors.** John Imray, 28, Southampton-buildings, Chancery-lane, London. (La Société Anonyme pour la Transmission de la Force par L'électricité, France.)

18274. **An improvement in electric arc lamps.** James Brockie, 28, Southampton-buildings, Chancery-lane, London.

18288. **Improvements in secondary or storage batteries.** Charles Riordon, 4, South-street, Finsbury, London. (Complete specification.)

18289. **Improvements in electric motors.** James Harry Keighly McCollum, 4, South-street, Finsbury, London.

SEPTEMBER 27.

18297. **Improved electric apparatus for striking bells and the like.** Denys Mathieu, 27, Martin's-lane, Cannon-street, London. (Complete specification.)

18328. **An improved method of duplex telegraphy.** George Edwin Fletcher, The Homestead, Call Green, Stockport.

18339. **Improvements in and connected with carbons for electric lamps or for other purposes.** Edward Goodrich Acheson, 55, Chancery-lane, London. (Complete specification.)

18359. **Improvements in or connected with electrical elevating mechanism.** Benjamin Willcox, 47, Lincoln's-inn-fields, London. (The Eisenwerk, late Nagel and Kaemp, Actien-Gesellschaft, Germany.)

SEPTEMBER 28.

18427. **Improvements in electrical traction and apparatus therefor.** Maurice Hutin and Maurice Leblanc, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

SEPTEMBER 29.

18480. **Improvements in automatic electrical gaslighters.** William Neely Jaskey and Edward Samuel Else, 18, Fulham-place, Paddington, London. (Complete specification.)

18501. **Improvements in or relating to incandescent electric lamps.** Walter Thomas Kerr, 232, High Holborn, London.

18507. **A quick-break electric lampholder.** Charles Otto Duetschmann, 8, Nag's Head-road, Ponders End, London.

18522. **Improvements in electric arc lamps.** William Smith Pendleton, 24, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, March 6, 1894, being date of application in United States.) (Complete specification.)

SPECIFICATIONS PUBLISHED.

1890.

12475. **Electrical smelting.** Taussig. (Second edition.)

14181. **Electrical railway fog signals.** Andrews. (Third edition.)

1893.

15050. **Electric bells.** Oppenheimer.

17521. **Illuminating by the electric arc.** Jackson and Dixon.

18115. **Electric arc lamp.** Borland.

20723. **Electric measuring instruments.** Goolden and Evershed.

20883. **Brackets for telegraphic, etc., insulators.** Bullers, Limited, and Chambers.

20915. **Alternate-current synchronisers.** Ayrton and Mather.

21327. **Electric meters.** Bergmann and Erben.

1894.

9862. **Primary batteries.** Morison.

14602. **Electromotors.** Canet and Hillairet.

NOTES.

Electric Lighting at Bombay.—The lighting of the Crawford Markets, Bombay, by electricity has been tried experimentally.

Electric Lighting at Colombo.—The electric light is being largely adopted in Colombo in various premises and for different objects.

Chinese and Indian Telegraphs.—A convention has been signed in connection with the Chinese and Burmese-Indian telegraph systems.

Electric Lighting at Buenos Ayres.—It is stated that a big syndicate of British capitalists has been formed to start in Buenos Ayres great works for the electric illumination of the city.

Electric Traction in Switzerland.—One of the electric tramways undertaken by the Compagnie de l'Industrie Electrique in Geneva was opened last month. The trolley system has been adopted with some modifications.

Award.—We are informed by Mr. C. A. Müller, of Bradford, who represents Messrs. Schuckert and Co., Limited, in this country, that the company have been awarded a *grand prix* for their exhibits at the Antwerp and Lyons Exhibitions.

Another Electric Light Installation in Calcutta. The United Service Club, Calcutta, has been fitted up with the electric light, and the installation will be ready in a week or so. The Madras Club has had the electric light for several years.

Institution of Civil Engineers.—This institution will continue to hold its meetings during the approaching session in the old theatre at 25, Great George-street, notwithstanding that the library and offices have been temporarily removed, during rebuilding, to No. 9 in the same street.

Indian Telegraphs.—The Indian Telegraph Report for 1893-94 has been submitted to the Government. It is believed that, excluding the cost of free and State messages, the interest on the capital is 2½ per cent.—the highest yet paid. Including the cost of free and State messages, the profit is about 4¾ per cent.

Cable Companies and the Chinese-Japanese War.—The cable companies must be profiting by the war. The long account of the battle of Yalu from the Central News correspondent cost no less than £300 to cable. There was also a telegram in the *Times* from Chefoo which must have cost as much to cable.

Telegraph Posts and Advertisements.—The City Council of Wellington, New Zealand, has passed a resolution "that the Government be requested to keep the telegraph posts free from advertisements, in view of the by-law passed by the Council which forbids the placing of advertisements on the electric light posts."

The Madras Electric Tramways Company, Limited.—The first 50 cars intended for this company have been fitted up at the Perambore Railway Workshops, and will shortly be made over to the tramway authorities. The cars are 24ft. long and 8ft. broad, and have compartments for first, second, and third class passengers.

Electric Lighting in Australia.—The Ballarat Electric Supply Company, Limited, of Ballarat, are going to erect a central station, the cost of which is estimated at £40,000. The local railway station and yards have agreed to take current. The consulting engineers to the company are Prof. Threlfall, Sydney, and Mr. Ellson, Adelaide.

Tramway Traction for Paris.—The deputation sent by the Paris Municipality, which consisted of Messrs. Rousselle, Thuillier, Attout-Taillefer, and Puech, to study foreign tramway systems, have returned. They have visited Zurich, Vienna, Budapest, Milan, and Geneva. They will draw up a report for presentation to the Municipal Council.

Institution of Engineers and Shipbuilders.—The eleventh annual meeting of the North-East Coast Institution of Engineers and Shipbuilders will be held in the lecture-hall of the Literary and Philosophical Society, Newcastle-upon-Tyne, on Tuesday next, at 7.30 p.m. The president, Mr. Thomas Richardson, will deliver his inaugural address.

Indian Electric Lighting Bill.—The public of Calcutta are greatly interested in the introduction of electric lighting, and now that it is known that the wave of enterprise is stemmed by the proposal to legislate in the matter, the enquiry is pretty general as to when the Bill is likely to be passed. We certainly agree, says *Indian Engineering*, that the delay already recorded is not creditable.

Electrolytic Production of Caustic and Chlorine It was mentioned on Wednesday at the annual meeting of the Aluminium Company, Limited, that the plant erected at Oldbury during the year for working the new electrolytic process for the production of caustic and chlorine had been in operation since the middle of July, with results which had more than confirmed the directors' most sanguine expectations.

"Elektrotechnische Zeitschrift."—Messrs. Gisbert Kapp and Jul. H. West have entered upon their duties as editors of the *Elektrotechnische Zeitschrift* with the current issue, dated 4th inst., and Mr. F. Uppenborn, the late editor, has retired, but will continue to contribute. Mr. Gisbert Kapp contributes an article on the lighting of Arundel Castle, respecting which he naturally knows more than a good many people.

The Hermite Electrical Sanitation Process.—The Ipswich Town Council decided at their meeting on Wednesday to adopt the Hermite process. This decision was unanimous, and resulted from the favourable report submitted by the Sewerage Committee on the trials which have been made on the main sewers of the town during the last three months. The permanent installation is to be proceeded with as rapidly as possible.

The Proposed Pacific Cable.—A cablegram from Ottawa (Ontario) says that, from information received by the Department of Trade and Commerce from a variety of sources, it is safe to predict that a considerable number of proposals will be received for the laying and operation of the proposed Pacific cable. It is expected that all the leading cable-making establishments of the world will be in vigorous competition with each other for the contract.

Electric Lighting in Austria.—The Government have approved of the successive introduction of the electric light into the various institutes of the university, according to as how funds permit thereof. During the summer the demand for electric light from the Internationale Elektricitäts-Gesellschaft, of Vienna, has been making rapid headway. The total number of lamps is over 92,000, and every day orders are coming in for more lamps to be connected and also for current for motors.

Books Received.—We have received the following new works: Fourth edition of Mr. Gisbert Kapp's "Electric Transmission of Energy" (Messrs. Whittaker and Co.); Mr. W. J. Buckley's "Electric Lighting Plants" (William

Digitized by Google

Johnston Printing Company, Chicago); "Durham College of Science, Newcastle-on-Tyne, Calendar" (Messrs. Andrew Reid and Co. and Messrs. Whittaker and Co.); and Mr. Herbert Laws Webb's "The Telephone Handbook" (Electrician Publishing Company, Chicago).

Prizes for Best-Kept Electrical Sections.—It will be recollected, says the *New South Wales Railway Budget*, that about a year ago the commissioners announced that prizes would be presented for the best-kept electrical sections, and prizes were presented at the time. Another year's results have now returned, and on the recommendation of the responsible officers the commissioners have approved of the prizes—£10 first and £5 second—being awarded to Mr. E. Jeator, relieving district electrical inspector, Eveleigh, and Mr. W. Barton, district electrical inspector, Hornsby.

Large Travelling Cranes.—With reference to our note in our issue of August 31 about the 60-ton overhead electric traveller at Messrs. Cockerill's works at Seraing and our query as to whether there were larger ones in existence, the *Western Electrician* of Chicago informs us that at the United States Government arsenal at Watervliet, New York, a 120-ton electric travelling crane is in operation. This crane is used in transporting the huge masses of metal that are worked up into the great guns turned out at the Watervliet works, and is probably the most powerful electric crane in the world.

Kashmir Postal and Telegraph Employes.—A large number of the employés of the Kashmir Postal and Telegraph Departments has addressed a memorial to the Maharajah pointing out that owing to the transfer of the State Post Offices and a greater portion of the telegraph lines to the Imperial Government, they are threatened with being thrown out of employment, and as they have spent the best part of their lives in the service of the State, they do not know where else to look for their livelihood. They pray that his Highness will take the petitioners' helpless state into favourable consideration and to represent their case to the Imperial Government with a view of inducing the latter to retain their services.

Electric Traction in Austria.—As we have already stated, a preliminary concession has been granted by the Government to the Länderbank for various electric tramways in Vienna. An official intimation has now been given by the Ministry of Commerce, allowing the bank to make technical preparations for the following underground electric lines: (1) from Ferdinandsbrücke under the Dominikanerbastei, the Woolzeile, the Stefansplatz and the Kärntnerstrasse to the Elisabethbrücke; (2) for a line from the Elisabethbrücke under the Operngasse, the Opern-Burg and Franzernsring, the Schottengasse, Freiung, Renngasse, the Concordiaplatz and the Heinrichsgasse to the Franz Josef-Quai; and (3) for one of two described lines from Opernring to the West railway station.

Medical School of the Yorkshire College.—The new medical school and the college hall of the Yorkshire College at Leeds were opened on Friday last by the Duke and Duchess of York. In honour of the event a conversazione, to which about 1,500 guests were invited, was held on Monday evening in the medical school, which was beautifully decorated for the occasion. The building, which is a handsome example of Tudor architecture, is one of the most perfectly equipped of its kind in the country. Lighted throughout by electricity, the arrangements of the lights bears witness to much careful consideration of the requirements for practical work, while at the same time, as was seen on Monday, a very pleasant and effective light is obtained for general purposes, and the entire installation, which has been carried out by Mr. T. Harding Churton, of Leeds, is very successful as regards both efficiency and effect.

Hong-Kong Electric Company, Limited.—The report of the Board of Directors to the fifth ordinary yearly meeting of shareholders, held at the Company's offices, Hong-Kong, on Monday, June 25, expressed their satisfaction at being able to point to a steady progress in the Company's business, the working account showing a credit balance of 6,310dol. 94 cents, which, transferred to profit and loss account, left a balance to the credit side of 7,248dol. 47 cents; while the amount overdrawn at the Company's bankers has during the year been reduced from 12,267dol. 17 cents to 6,339dol. 97 cents. Although there had not been that rapid extension of the Company's operations which the directors had hoped for, there was a steady increase in the amount of house-lighting, and the benefit from the installations now being fitted would soon be showing itself in the earnings. It was not intended to fill the vacancy on the Board caused by the death of Mr. J. S. Lapraik.

Electric Lifts on Board Ship. — Mr. Arthur L. Gibson, secretary to the Otis Elevator Company, writes to the *Times*: "I note in your issue of the 5th inst. a communication from 'A Traveller,' in which he asks if it 'would not be possible to have lifts constructed in the floating hotels which now cross the seas in every direction, by which invalids could be carried up and down from the levels of their berths.' In the *Mechanical World* of August 31, 1894, on pages 86 to 88, 'Traveller' will find illustrations and plans of the new American steamship 'North-West,' with a length over all of 383ft., and a gross registered tonnage of 4,244 tons. This ship was built for service on the great lakes. It is a first-class passenger steamer, and, among its other fittings, is provided with an electric lift from the cold storage rooms to the galleys, pantries, etc. From this to the provision of a lift for passenger service is but a step, and we may perhaps expect to see in the not distant future large passenger ships supplied with electric lifts for the use of passengers."

Electric Lighting in Germany.—At Hamburg the electric mains have been completed for some time in the town proper, and they are now being laid in St. Georg and in the Steindamm. Mr. Hippmann, the owner of the Kurgarten at Munich, has expressed himself willing to undertake the electric lighting of the Nymphenburg. At Altena, near Plettenberg, Messrs. Basse and Selve, the owners of some large copper-rolling mills, will light their works electrically, and also supply current for the lighting of the railway station and the neighbouring streets. Seven firms have tendered for the central electric light station at Görlitz. Mr. Friedr. Ross, of Vienna, has been selected to adjudicate upon the various plans. A central electric light station has been established at Eibau by Messrs. Nitzschmann and Zschockelt. Plans are being made for a transmission of power and lighting plant at Gersthofen-Augsberg. The local authorities at Laibach propose to introduce the electric light, the water power of the Save being utilised for the purpose. Messrs. Brandes and Co., who have the concession for the electric tramway between Brunswick and Wolfenbüttel, propose to light the Neue Weg there by electricity.

Mason College, Birmingham.—For several years it has been the custom for Mr. Turner, the late lecturer on metallurgy at Mason College, to give a short course of evening lectures on some subject connected with local metallurgical industries, and these lectures have been very

Digitized by Google

well attended. His successor, Mr. W. G. McMillan, proposes to continue these lectures, and has issued the syllabus of a popular course on "The Scientific Principles of Electro-Plating," to be given by him at Mason College on five Thursday evenings, at eight o'clock, commencing yesterday. Mr. McMillan, who is the author of the treatise on electro-metallurgy in Griffin's Scientific Text-book Series, proposes to deal with the subject in the following manner: (1) Chemical and physical laws influencing electro-deposition; some characteristics and sources of the electric current. (2) Depositions of metals by simple immersion; cause and limitation of such deposits; conditions favourable to such depositions, and character of the deposits. (3) Deposition by separate currents; effect of current strength on the character of deposits; disposition of plant; relations between electrodes, solution, and current strength; use of insoluble anodes. (4) Conditions governing purity of deposit; deposition of alloys; secondary or chemical action of the solution upon deposits; refining of metals. (5) Stripping, cleansing, and polishing of surfaces; tests of materials used in electro-plating. An additional course of study in general practical metallurgy may be followed on Friday evenings from seven to nine, beginning on 12th inst., in the metallurgical laboratory. The subjects specially dealt with will be fuel, iron and steel, copper and its alloys, the precious metals, and electro-metallurgy. At least 20 lessons will be given.

The Bankside Accident.—Mr. A. W. Wyatt has held an inquest at Southwark on the body of Henry Hearne, 29, a fitter's labourer, in the employ of the Brush Electric Light Company, 64, Bankside, Southwark. John Gales, a fitter in the same employ, said deceased had worked under him about two months. About four o'clock the previous Sunday afternoon witness noticed that the machinery worked stiffly, and ascended to the top of the switch pillar of one of the alternators to see where the mistake was, and left deceased standing at the foot of the ladder. About 20 minutes afterwards witness heard a scream, and upon looking round he saw Hearne lying on the ground at the foot of the next pillar with the ladder lying beside him. Finding him unconscious, the manager and a doctor were at once sent for. The switch pillar that witness was attending to was not in use, and was consequently termed "dead." Witness could not say why Hearne attempted to climb on to the next pillar, which was "alive." Witness did not see him take the ladder away. He did not send deceased to No. 6 pillar for anything. Deceased should have remained at the bottom of the ladder till witness had finished the job. Hearne had been cautioned by the witness and the manager on several occasions not to touch anything without receiving instructions. The Coroner: Do you think he got tired of holding the bottom of the ladder, and climbed on to the live pillar out of curiosity? Witness: I cannot say. I know of no reason why he should go there. Witness had never known Hearne to leave his work before. The distance between the pillars was about 19ft. A Juryman: Can you suggest the cause of deceased falling? Witness: The ladder might have slipped while he was ascending it, and clutching one of the rods to save himself received the shock. Arthur Henry Foster, practical engineer to the company, said that he was in his office last Sunday afternoon, and noticed the lights suddenly flicker. Upon going to the pioneer station to ascertain the cause, he was informed of the occurrence. He saw the deceased being supported by two men. Artificial respiration was resorted to, but without success. The machine in question was sufficiently powerful to kill a man. The flickering was very noticeable, and occurred three times in succession. The switches on the top of the pillars were always "alive" unless under repair. Witness was totally at a loss to account for the accident. Dr. J. G. Garbett, of 49, Sumner-street, Southwark, stated that upon his arrival life was extinct. Witness had made a *post-mortem* examination, and found the heart contracted. There were several marks on the outside of the right arm, with corresponding holes in the shirt sleeve, and the skin was stained red. The cause of death was stoppage of the heart's action, consequent upon electric shock. The jury returned a verdict that death was due to electricity through touching a charged portion of machinery, but for what purpose there was no evidence to show.

Electric Aura in Varicose Ulcers.—The effect of static electricity on the healing of certain skin diseases and ulcers has been studied by Prof. Doumer, of Lille, says the *Lancet*. In the case of ulcers of the leg he has obtained very satisfactory results. The ulcer is first washed with some antiseptic solution, and then covered with a thin layer of absorbent cotton wool. The patient is then placed on an insulating stool and connected with the negative pole of an electrical machine. The positive electrode is now brought near enough to the ulcer to cause the passage of the electrical aura, but not that of any spark. This aura is allowed to play on the part affected for about 10 minutes, and cotton wool dressing is then applied. These sittings are repeated twice a week. Where the ulcer is due only to a varicose condition or a blow, immediate improvement is generally manifested, the pain and itching disappearing very quickly and afterwards the swelling, the ulcer ultimately healing over. Where, in addition to the varicose condition, the patient is greatly debilitated by old age, Bright's disease, or other chronic affection, the action of the electric aura is far less effective. M. Marquant, who has published an account of Prof. Doumer's observations, mentions, amongst others, the case of an elderly man who had formerly been given to drink, and who had large varices. In consequence of a blow an ulcer appeared on the leg, measuring ultimately 20 millimetres by 17 millimetres; it was insensitive, and secreted a sanious discharge, the surrounding skin being of a violet colour. The tibia was swollen for seven centimetres of its length. Near the centre of the bony swelling, close to the ulcer, there was a fluctuating surface of the size of a two-franc piece, very sensitive to pressure, and here the finger came upon a cup-shaped depression in the inflamed periosteum. This patient was treated for three weeks with antiseptic dressings without any marked change. The electric aura was then resorted to with immediate benefit; the sittings were continued daily, and from the third the pain and swelling decreased. A few days later the size of the ulcer had diminished, the periosteal infiltration had disappeared, and the patient could walk without limping. In three weeks cicatrisation was complete and the ulcer has shown no signs of returning

Halifax Central Station.—Seven months ago building operations were started in connection with the central electric light station, but the change made at the bottom of Foundry-street, where the works are situated, is remarkable. An old stone mill and a reservoir have disappeared, and on the same site there has risen an extensive building. The boiler-house is large enough (140ft. by 50ft.) to contain nine boilers, each of 300 h.p. The three laid in their beds now are the make of Messrs. Yates and Thom, of Blackburn, and a fourth is to come. Beside them, fixed in the main flue, is one of Green's economisers of 240 pipes; the chimney, of stone, will rise beside this building some 150ft. The boiler-house has a steel roof, level with the

Digitized by Google

adjacent railway. This has been so constructed to admit of a small siding being made, whereby trucks of coal can run direct on to the aforesaid roof, which will be utilised as a coal-store. The store will have a capacity of 1,000 tons, and the coal will be passed into the furnaces by mechanical stokers. The water for condensing purposes will be drawn from four springs which have been bored in the property, and it will be stored in a cement-lined tank capable of holding 100,000 gallons. On the upper side of the boiler-shed is the engine and dynamo room, lofty, well lighted, and its lining of white glazed bricks gives it a very smart appearance. The room is 110ft. long and 55ft. wide. It is proposed to erect here five engines, two of 200 h.p. each, one of 100, and two engines of 25 h.p. each, the first three being supplied by Messrs. Pollit and Wigzell, of Sowerby Bridge, and the small engines by Messrs. Robey, of Lincoln. One of the large compound condensing engines has been embedded this week. The room is large enough to accommodate twice the number of engines on order, and several beds are to be prepared ready, in anticipation that they will be required before long. To facilitate such works, and the repair of the engines, a crane that will lift 15 tons travels overhead. The dynamos are of the same power as the engines that drive them. The three laid down will supply current for 4,500 lamps of 16 c.p. Twenty miles of cables have been laid in the town, and about 100 applications have been made for the light, representing about 2,500 lamps. The Joint-Stock Bank directors have placed one of the most recent orders for the light, and other banks, it is believed, are considering a similar policy. Nearly all the tradesmen in Crown-street are going to have it, and connections have been made in the cases to a few private houses. Mr. Wilmshurst, the engineer, states that in about six weeks' time he hopes to be able to supply current for the whole of the mains laid. Mr. Wilmshurst, questioned as to whether the introduction of the electric light so extensively would not act detrimentally upon the gasworks, answered in the negative, his reason being that there was an ever-increasing demand for gas for engine and heating purposes, and the very fact of one tradesman having electric light would either induce his neighbour to go in for the same illuminant or for an additional power of gas.

The Cost of the Electric Light.—Mr. Henry A. Mavor writes to the *Glasgow Herald* on this subject as follows: "I agree with you that the main line of comparison between gas and electricity for street-lighting must proceed on the question of cost. Electric light on streets is no better than gaslight *per se*. The comparison of cost must, however, be made fairly—light for light, and total cost against total cost. It will not do to compare the two on the simple basis of cost of gas supply against cost of electric supply at the ordinary rates to consumers. Further, it is not quite safe to settle the question generally from the conditions in any one town. For the present purpose, however, we may consider the case of Glasgow on the lines which you have chosen. I am unable to check your figures of gas consumpton in Welsbach burners, but assume their correctness as a basis of calculation. Turning now to your comparison of costs, I would point out that your estimate of the light per Board of Trade unit is approximately correct for small incandescent lamps, but is not nearly so for large incandescent lamps or for arc lights. The actual state of affairs is thus:

Incandescent lamps of 16 c.p.	3 watts per candle-power.
,, ,, 150 c.p.	2 ,, ,,
Ten-ampére arc lamps of 1,000 c.p.	½ ,, ,,

(In this connection it should be noted that in street-lighting the arc lamp is at its best advantage, for the most effective part of the area of light is exactly where it is wanted, there being no walls or ceiling to illuminate.) Now, as to the price per unit. The price of 6d. charged to the public is no guide to the cost of street-lighting. It will be seen that the street-lighting which goes on during all the hours of darkness—viz., about 4,000 hours per annum—is very much more profitable work for the machinery than private lighting, which gives an average use of less than 500 hours. Taking the price of £26 per 1,000-c.p. lamp per year of 4,000 lighting hours, as stated in your article, the cost per unit would be 3·12d. With these corrected figures the cost of the electric energy against gas would be, on the same basis of comparison as given in your article—

Electric arc light—amount of light obtained for 5s. at the rate of 3·12d. per unit is 38,460 candle-power hours	5s.
Ordinary gas burners, taking five cubic feet for 20 c.p. for one hour—9,615 cubic feet at 2s. 6d.	24s. 0½d.
Regenerative burners	11s. 4d.
Incandescent gaslight	5s. 8d.

(In the latter three cases the ratios of cost are taken from your article.) It will thus be seen that, light for light, the arc lamp, so far from costing more than 12 times the incandescent gaslight, is actually cheaper. Time does not permit me to show in this letter a comparison between smaller electric lamps and the incandescent gas lamp, but the calculation is a simple one, the items on either side being:

Electric.	Gas.
Cost of current.	Cost of gas.
Repairs and renewals of lamps.	Repairs and renewals of mantles.
Wages of cleaners.	Wages of cleaners.
(No lamplighters.)	Wages of lamplighters.

In Glasgow it would probably be found that it would be cheaper to use gas lamps in the suburbs, but it seems doubtful whether the following disadvantages of incandescent gas lamps can be overcome so as to warrant the abandonment of the present system of gas burners: (1) skilled labour fixing and maintaining mantles; (2) reduction of downward lighting power by form of burners; (3) loss of mantles and funnels from draught; in short, all the difficulties which have prevented the adoption of regenerative burners, and which appear with tenfold force in the Welsbach system."

Electricity v. Gas.—The first of a series of popular lectures for the session at the Merchant Venturers' Technical College, Bristol, was delivered by Prof. J. Wertheimer, B.Sc., B.A., principal of the college, his subject being "Electricity *v.* Gas." After explaining the methods of producing gas and electric current, he summarised the arguments for and against the adoption of electricity in place of gas. It was pointed out that, if electricity were carefully used, it was scarcely, if at all, dearer than gas, and that it was certainly cheaper for illuminating large areas. The only possible argument against electricity was its cost; and it was exceedingly likely that electricity would become very much cheaper as improvements continued to be made, and that it would ultimately come to a figure at which it would easily compete favourably on this score also with gas. "So much the more reason to delay the use of electricity till the time when it should be economical," said the opponents of electric lighting. But they might fairly reply to that—that the least expensive article was not always the cheapest in the best sense of the word; for coal gas, as compared with electricity, must be placed on the disagreeable list of things which were cheap and nasty; for they must remember that fresh, pure air was one of the most important health factors, especially in great towns, where the air was at best never too pure. Those who had ever been in that or any other crowded room when lit by gas, and visited it under similar circumstances when electricity

Digitized by Google

had been substituted, would fully realise the force of this remark. It was sufficient to remember that three gas jets in a moderate-sized room spoiled an enormous quantity of air in an hour, while an equivalent quantity of light produced by electricity would not affect the air at all. It must, moreover, be remembered that gas lighting was a fertile source of dirt, while nothing of the kind occurred with electric lighting, and that when electricity was suitably dealt with it was absolutely safe. They might then confidently predict that the gradual replacement of gas by electricity would tend to lengthen the lives of all by removing a constant and all-pervading source of air contamination, and that this fact alone would settle the question as to which was to be preferred, except for those persons who did not consider the extension of their lives worth the comparatively small difference in cost which would exist where electricity was not carefully used. When once such individuals had been eliminated by the action of the survival of the fittest principle, they would find coal gas consigned to its proper place, and used only in the production of heat, or as a source of motive power in gas-engines. Under the auspices of the Corsham Technical Instruction Committee, Prof. W. Wilson, M.A., one of the extension lecturers of the Merchant Venturers' Technical College, Bristol, has delivered a lecture in the Town Hall on "Electricity and its Applications." The chair was occupied by Mr. G. P. Fuller, M.P., and there was a very large attendance. The lecture was fully illustrated by means of experiments and lantern slides. The lecturer explained the elementary principles of magnetism, pointing out the importance and meaning of magnetic fields. He explained what was meant by the term electric current, and showed by experiments the various effects which a current can produce. He next showed the production of the current by chemical, thermal, and magnetic means, pointing out that in every case energy was required for its production. Proceeding to deal with the applications of electricity, the lecturer demonstrated the elementary facts of telegraphy, telephony, and electroplating. The very important development of the utilisation of electric currents for mechanical purposes by means of electromotors was fully explained.

Durham College of Science.—Two new wings of the Durham College of Science, which was commenced in a modest way in Newcastle some 24 years ago, were opened on Tuesday by the Mayor, Alderman Stephen Quin. The College of Science represents in Newcastle the faculties of science and engineering in the University of Durham, and its students obtain the science degrees and engineering diplomas of the parent university. The first portion of the college built was the north-east wing, opened in 1888. The buildings opened on Tuesday were the south-east and south-west wings of the college, forming two sides of the quadrangle. The new portion comprises a large central tower and the chemical lecture theatre, together with the whole of the buildings for the engineering and art departments. In the centre of the south-east wing is the Royal Jubilee Exhibition Tower, which forms the permanent and only memorial of the Jubilee Exhibition. The gateway forms a noble carriage entrance to the quadrangle, the roof being groined in stone, with red brick filling the spandrels. In the front of the tower are the Royal medallion and the college arms. The gateway is surrounded by four octagonal "sentinel" turrets, each 95ft. in height, and surmounted by ornamental ironwork. The turrets are made to serve respectively for (1) chimney; (2) ventilating-shaft; (3) experimental tower, with a mercury column 100ft. high for testing gauges; and (4) a coal hoist and staircase. Above the gateway are the following rooms: in the Jubilee Tower—classroom for general purposes, two private rooms for professors, common room for art masters, and professors' common room. On the right of the gateway are the following rooms on the ground floor: chemical lecture theatre, which is very similar to the physical lecture theatre, and above the theatre are five rooms intended for special and advanced work in chemistry, but some of which at present afford accommodation for the agricultural department. A large classroom occupies the mansard roof above the last-mentioned rooms. Between the north-east wing and the gateway is the boiler-room, affording accommodation for two Lancashire and one marine boilers, with measuring tanks and other appliances for conducting efficiency and other tests. It is a single-storey building enabling the boiler to be placed quite outside the main building. On the other side of the gateway, on the ground floor, are the following rooms: metallurgical laboratory, with wind furnaces, muffle furnaces, and assay furnaces, and fitted with working benches for 24 students; next to it the engine-room, where the principal electric light engines are accommodated. This room is situated in the south corner of the building, and adjoining it, forming the ground floor of the south-west side of the quadrangle, is the George Stephenson engineering laboratory. The principal portion of the laboratory is 123ft. long and 35ft. wide, but this is supplemented by an annexe 9ft. wide throughout the greater part of its length. A bust of the late George Stephenson, presented by Mrs. Robert Stephenson, adorns one end of the laboratory. Above the George Stephenson engineering laboratory is the engineering drawing office and mechanical museum. Next to the drawing office in the south corner is the engineering lecture-room, and adjoining this is the metallurgical lecture-room. The whole of the second floor of the building is devoted to art. The whole buildings will be heated by exhaust steam from the main engines, and will be lighted by electricity. The Stephenson laboratory will contain the 100-ton testing machine given by Mrs. William Clarke, the experimental marine engines, oil-testing engine, bar-testing machine, dynamometers, tools for the construction of the apparatus for test pieces, and all the varied experimental apparatus for mining, naval construction, and applied mechanics. Power will be available at all points in the laboratory. The architects for the college buildings have been Mr. Johnston, F.S.A., and Mr. Frank W. Rich. The portion yet to be built is the main wing, facing the Castle Leazes, and some £90,000 is required to complete the college buildings and to relieve the council of their liabilities. Among the professors and lecturers in the college may be mentioned: Principal, the Rev. Henry Palin Gurney, M.A. (Cantab.), F.G.S. Mathematics: Prof. R. A. Sampson, M.A.; lecturer, C. M. Jessop, M.A. Physics: Prof. H. Stroud, M.A., D.Sc.; hon. professor of physics and experimental philosophy, A. S. Herschel, M.A., D.C.L., F.R.A.S.; lecturer, R. J. Patterson; assistant lecturer and demonstrator, Victor A. Mundella, B.A., B.Sc. Chemistry: Prof. P. P. Bedson, M.A., D.Sc., F.T.C., F.C.S.; lecturer, Saville Shaw, F.C.S. Engineering and naval architecture: Prof. R. L. Weighton, M.A.; lecturer in engineering, R. M. Ferrier, B.Sc., C.E. The secretary of the college is Mr. H. F. Stockdale. Among those who have made gifts of appliances and other requisites to the engineering laboratory are the following: Messrs. Scott and Mountain, Newcastle; Messrs. Palmer and Co., Jarrow; Messrs. Clarke, Chapman, and Co., Gateshead; Messrs. Tangyes, Birmingham; and Messrs. Pyke, Harris, and Co.

THE ELECTRICITY WORKS AT WORCESTER.

NOVEL WATER-POWER STATION.

General Remarks.

The undertaking which was inaugurated yesterday by the Corporation of Worcester is one of the most interesting and novel central electric light stations in the United Kingdom. The utilisation of water power, as is the case in that city, has met with little support in this country, and the Corporation of Worcester are to be congratulated upon having been the first to practically demonstrate on a fairly large scale what can be accomplished in this direction for both public and private lighting.

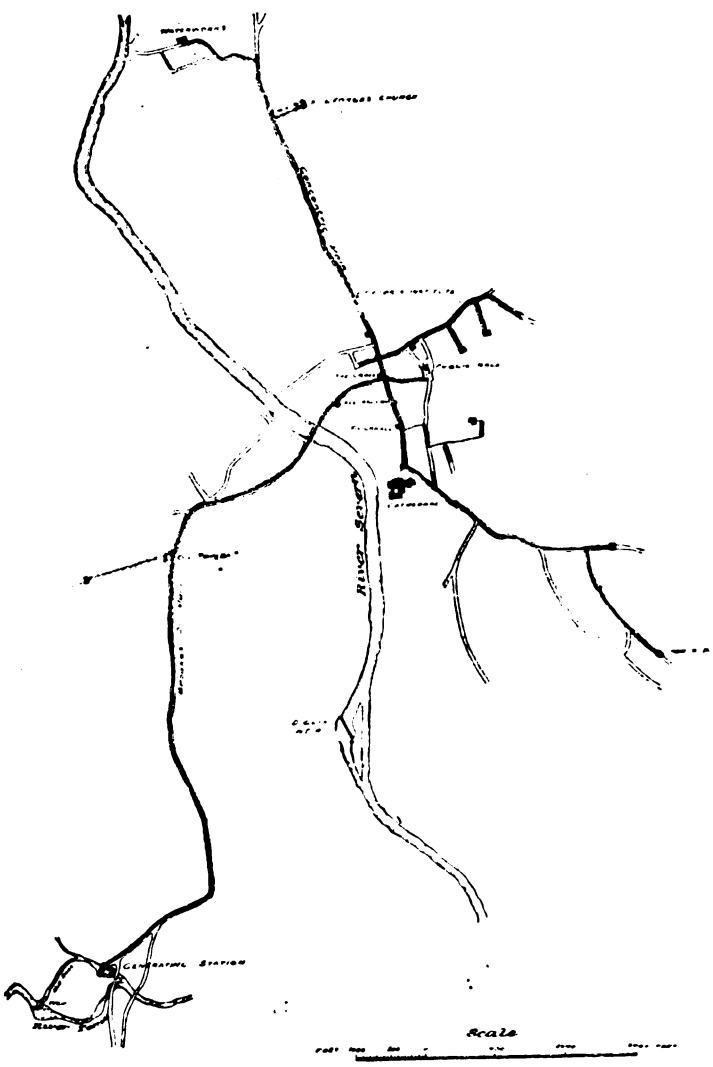
A few private individuals, as will be recollected, have in operation small installations, the power for which is obtained from a fall of water. At Keswick, for instance, water power is employed, whilst at Blockley, a village not many miles from Worcester, there are some 20 or 30 incandescent lamps energised from a water-power station. A curious feature—a fact we are assured—is that the tiny Blockley central station is worked by the village blacksmith. If this is correct, the owner doubtless understands sparking as much as anyone. From the present, Worcester will stand forth as the first important example of the use of water power in England.

MR. THOMAS CAINK,
Electrical Engineer to the Worcester Corporation.

But the Corporation have gone further. They have combined water-power plant with steam-engines, and have brought to a satisfactory conclusion a central station which deserves the particular attention of municipal authorities, engineers, and others concerned with the practical applications of electricity in everyday life. Provision has already been made for a day load at the waterworks (to which reference will be subsequently made), whilst it is proposed, on the completion of the projected new sewerage works for the treatment of the sewage before being discharged into the Severn, to pump the sewage by electricity. In fact, the electricity works have been planned and carried out in such a manner that it is expected the steam plant will only be used during the hours of heavy load in the evening, and in this way it is anticipated that the most economical working results will be obtained.

Municipal Works.

A very ancient city is Worcester. Like most cathedral cities, it has frequently been characterised as sleepy. It has, however, not only kept abreast of the times, but also in advance of most cities of this nature. It is governed by a Mayor and Corporation, consisting of 12 aldermen and 36 councillors. A complete main drainage scheme was carried out in 1856, and the present waterworks are the property of the Corporation. The town is provided with a public library and reading-room, and a natural history museum. The library and museum will shortly be removed from the present building into the block of buildings now being erected at a cost of over £20,000 for that purpose, and also for technical schools. A new infectious diseases hospital is shortly to be built, and an extension of the waterworks and a new high-level reservoir, at a cost of £15,000, have just been completed. Besides the foregoing works, and the £50,000 borrowed for electric light, the Corporation have subscribed towards the improvement of the Severn navigation, and they have also just decided to purchase Pitchcroft for a public recreation ground at an ultimate cost of £14,000 to £15,000, and have also carried out a large number of street improvements, including the



Worcester Central Station.—Map of District, showing the Site of Generating Station and Lines of Mains.

paving of nearly the whole of the footpaths and courts within the city boundary. Thus it will be seen that the Worcester Corporation is a fairly progressive body. The Board of Guardians have expended £40,000 on a new workhouse and cottage homes.

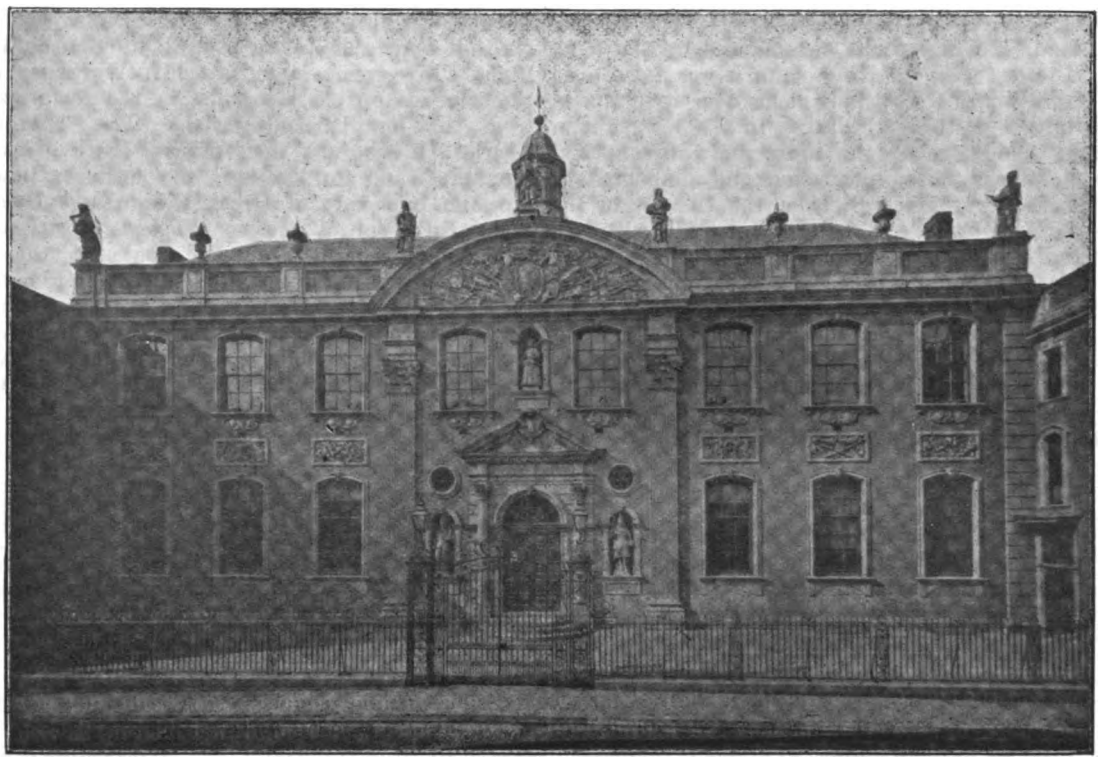
The most prominent of the public buildings in Worcester is the cathedral. Among others may be mentioned the Guildhall, in Queen Anne's style, and here the public offices are situated. An external view of the Guildhall (which is situated in High-street, a main thoroughfare) is annexed. The county offices, including the assize courts, are located at the other end of the town from the Guildhall. These form a block of buildings in classical style, standing well back from the road. The Corporation also own the building in which an electrical exhibition was opened yesterday.

Digitized by Google

This building is known as the Public Hall, and it is used for concerts and public meetings. The theatre, termed the Royal, is situated in Angel-street.

Historical.

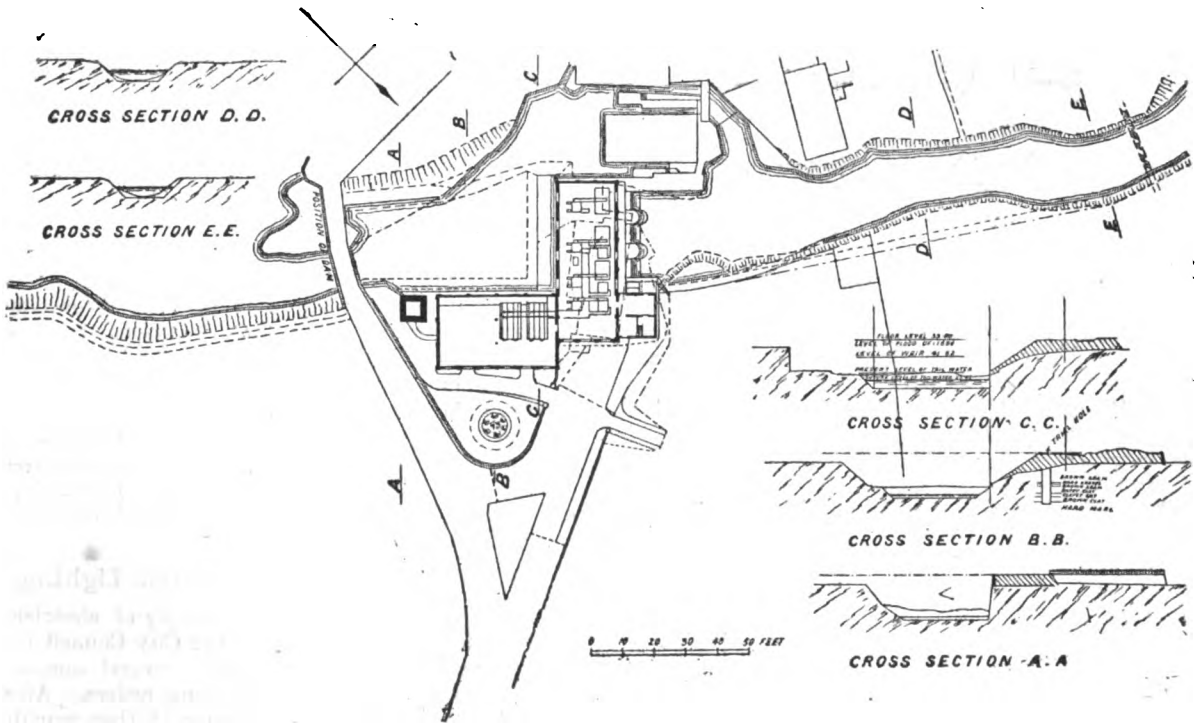
As already remarked, Worcester is a very ancient city, with a long history of war, siege, fire, and plague. The



Worcester Guildhall

The town is well provided with markets, including one for cattle, a fruit market, one for poultry, vegetable and meat markets, and a large corn exchange. One of the most important local industries is the hop trade. The other leading branches are the manufacture of porcelain, gloves, sauce, and an extensive vinegar manufactory.

town, which was generally supposed to have been founded by Constantus Chlorus, was called by the British "Caer Wrangon," or "Caer Guorangon." It was afterwards taken by the Romans, and called by them Vigornia. It was next occupied by the Saxons, during which time it was constituted a city by Wulphere, king of Mercia.



Worcester Central Station.—General Plan of Works.

Among the miscellaneous factories are two large signal and general engineering works, each of which employ a large number of men. The population of Worcester comprises some 43,000 persons, and the town covers an area of 3,185 acres.

After the union of the Saxon kingdoms the Bishop of Worcester obtained certain Royal grants from Offa and Edgar, which enabled him to fortify the cathedral and close, parts of which remain, known as the Edgar Tower, bearing the date, to the present day. The city was twice

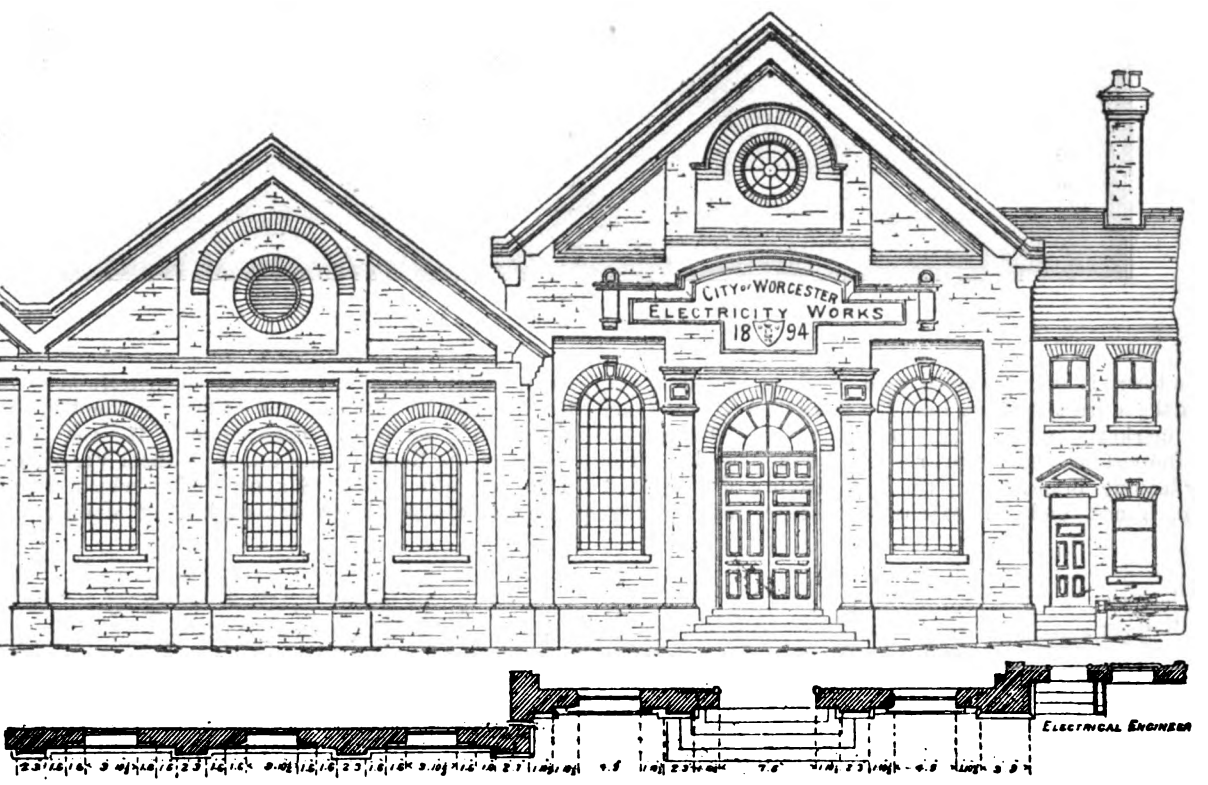
Digitized by Google

destroyed by the Danes. In the time of the Conqueror, Worcester was an important place, and had a mint. At that time it repeatedly suffered from the inroads of the Welsh. The castle was then built, the ruins of which have recently been laid out as a promenade by the Dean and Chapter. Worcester was sacked and burnt by the Empress Maud, and afterwards taken and burnt by King Stephen. In the reign of King John it was taken and retaken several times. The king at his own request was eventually buried in the cathedral. In 1263 Sir Simon de Montfort laid siege to the town, and after several unsuccessful attacks seized possession and plundered it. In 1265 Prince Edward escaped from the custody of the barons at Hereford Castle and fled to Worcester, where he speedily raised an army, which enabled him shortly afterwards to defeat the barons in the famous battle of Evesham, which victory again restored the regal power to England.

An interesting municipal event occurred in 1281, when it was recorded that Godfrey Giffard, Bishop of Worcester, laid the first stone of the pavement of the town. In 1299 the wooden bridge across the Severn was destroyed by fire; a new stone bridge was built in 1313. In 1401 Worcester was again burnt and plundered, this time by Owen Glendower's troops with their French auxiliaries. In 1484 a flood took place, which carried away men, women, and children. This was called the Duke of Buckingham's water, because he lay with an army of Welsh ready to attack Richard III., but was stopped by this flood, which was so sudden that in one night it rendered the passage everywhere impossible. While waiting for the flood to subside, his men, for want of provisions, deserted him, and so this inundation secured Richard III. in his usurped dominion. In 1637 a plague raged in the city, causing the inhabitants to fly on to the island of Beveré, in the Severn, and the city remained deserted and desolate for some time.

During the time of the King and the Parliament Worcester repeatedly suffered, and was laid siege to in 1642 by the Earl of Essex. After a siege of several days one of the first battles of the Civil War took place on Pitchcroft (acquired by the Corporation for a public recreation ground) between the Royalists, commanded by Prince Rupert and Prince Maurice, and the Parliamentarians, by Colonel Sandys. As a result the Royalists were routed, and the city was taken the next day by the Earl of Essex, and again the town was terribly plundered. But Worcester was too loyal a city to long remain under the Parliament. Thus, in the year 1646, the Mayor and Corporation, after the Parliamentary troops had left the city, declared the city in favour of the King, and immediately commenced to raise money to rebuild the fortifications for the King. This again brought the Parliamentarians down upon them. A long siege ensued, and the citizens were finally starved out, but were able to capitulate this time on honourable terms. Five years later, in 1651, Worcester was again the scene of terrible bloodshed, as the town was wrested from the few Parliamentarians then holding it by Charles II., who was then received with great state by the Mayor and Corporation, who solemnly proceeded to proclaim him king of Great Britain and Ireland. The great battle of Worcester followed shortly afterwards, this ending in the complete route of the Royalists. Worcester was once more pillaged and burned, and the walls thrown down. Thus, as the historian says, England's troubles began and ended at Worcester.

Since these troublous times Worcester has shared in the prosperity and vicissitudes of the country generally. A very interesting fact is that the city seems to have been amongst the foremost towns in the adoption of improved systems of public lighting. It is recorded that in 1794 Worcester was amongst the many towns that, "availing itself of the essential benefit derived from paving and lighting on the improved modern plan, carried both into the fullest effect under an Act of Parliament passed in the year 1783." Gasworks being opened in the year 1819, this quickly superseded the oil lighting "on the modern improved plan of 1794." To the modern improved plan of 1894, just a century later than the introduction of oil illumination, a longer life is, of course, anticipated.



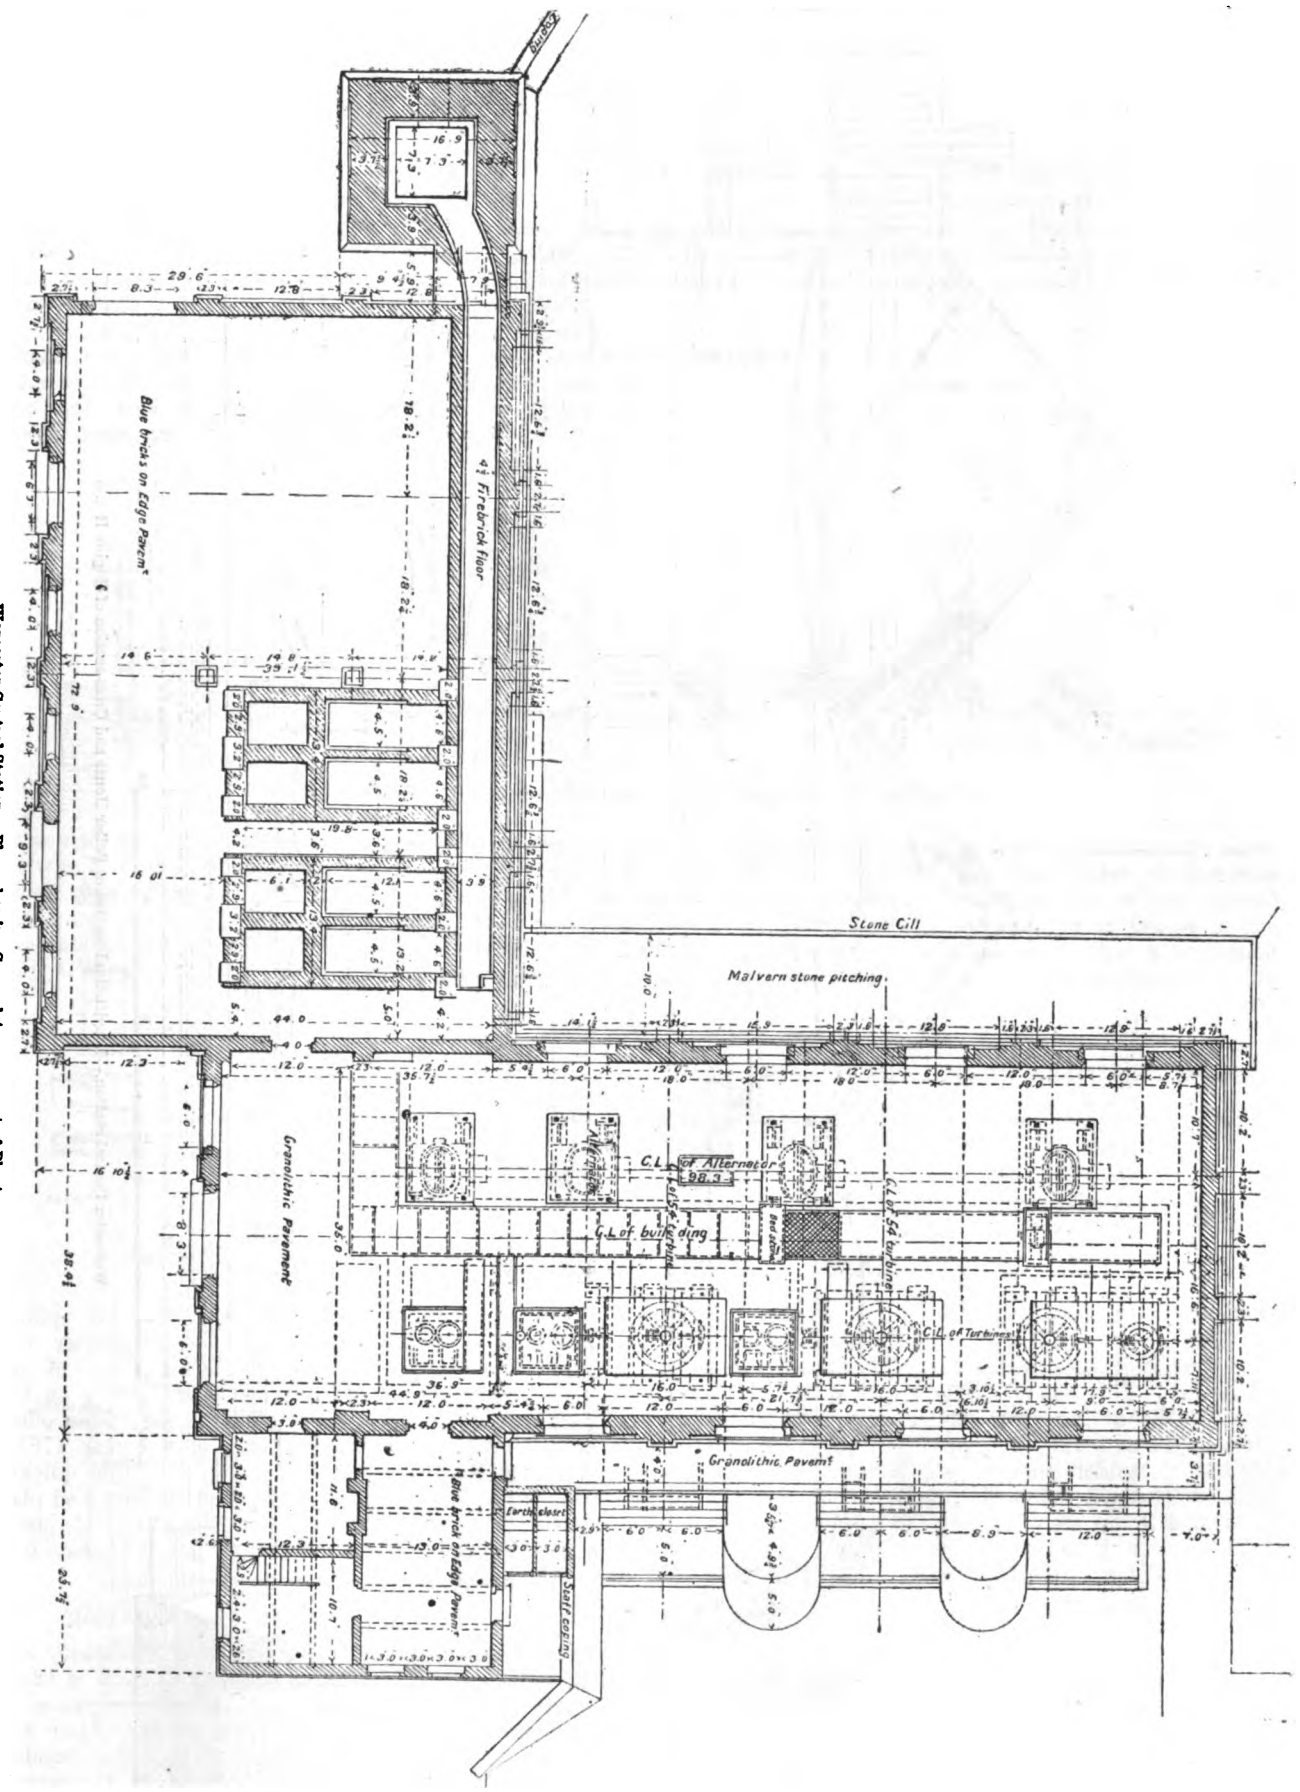
Worcester Central Station.—Portion of North-East Elevation.

Preliminary Steps in Electric Lighting.

The subject of introducing a supply of electricity was first brought under the notice of the City Council in 1889, when intimation was received from several companies of their intention to apply for provisional orders. After due consideration, the Council in October of that year decided to apply for electric lighting powers. Originally, the capital outlay for the proposed electric light works was estimated at £15,000, but only a small area of the city was intended to be lighted. The provisional order was granted by the Board of Trade, and the Confirmation Bill received the Royal assent on August 4, 1890. The order authorised the Council to supply electricity throughout the whole

Digitized by Google

city, but the streets in which the supply was made compulsory were confined to the centre of the city. The maximum charge authorised by the order was 8d. per unit The Council on October 7, 1890, decided to consult Mr



Worcester Central Station.—Plan, showing General Arrangement of Plant.

G. E. Pritchett as to the best way of carrying out the order, and whether the work should be done by the Council or handed over to a company. Mr. Pritchett in his report presented in November, 1890, while recommending that the Council should establish a municipal supply, suggested that a decision on this point should depend upon the probable demand for light. The report contained the first practical reference to the use of water as a motive power for the Worcester works, it being suggested that the Diglis weir should be used for this purpose.

The report having been discussed, the matter remained in abeyance until May 15 of the following year, when Mr. J. Millington, the present city high sheriff, offered to accept a transfer of the Council's powers under the provisional order, and to repay to the Council the cost of obtaining that order. This offer was declined, and the Watch Com-

Digitized by Google

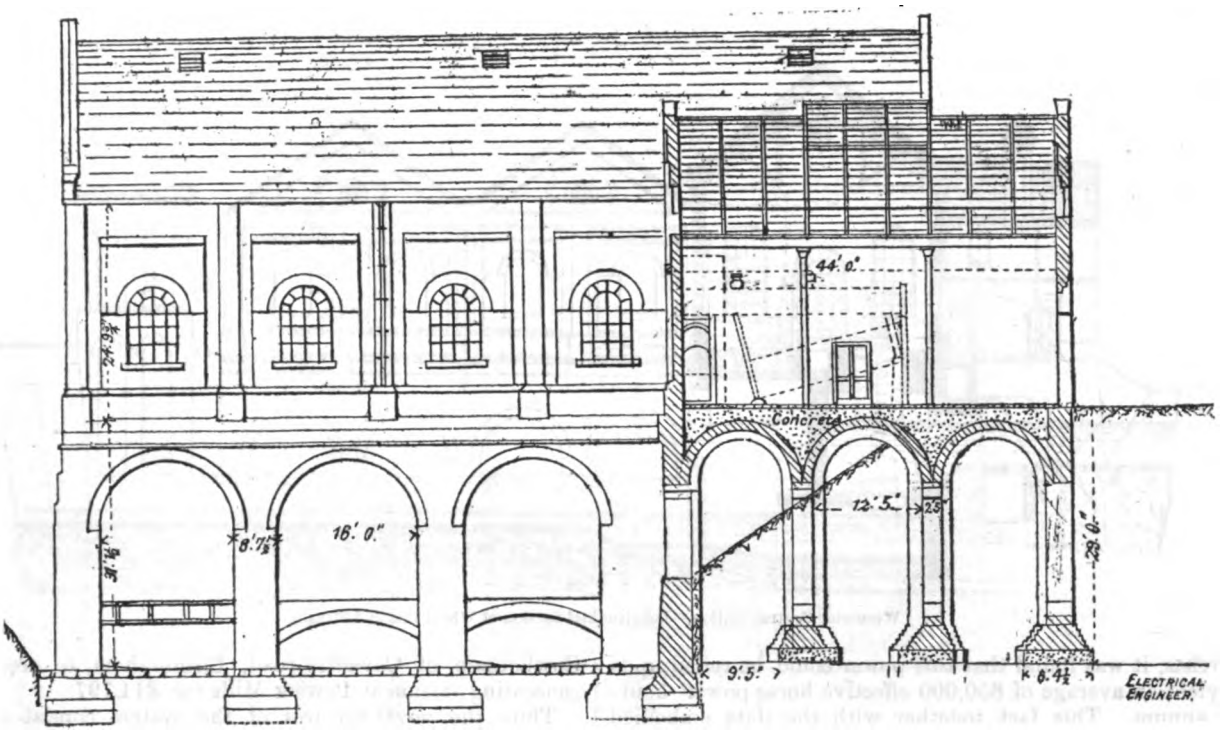
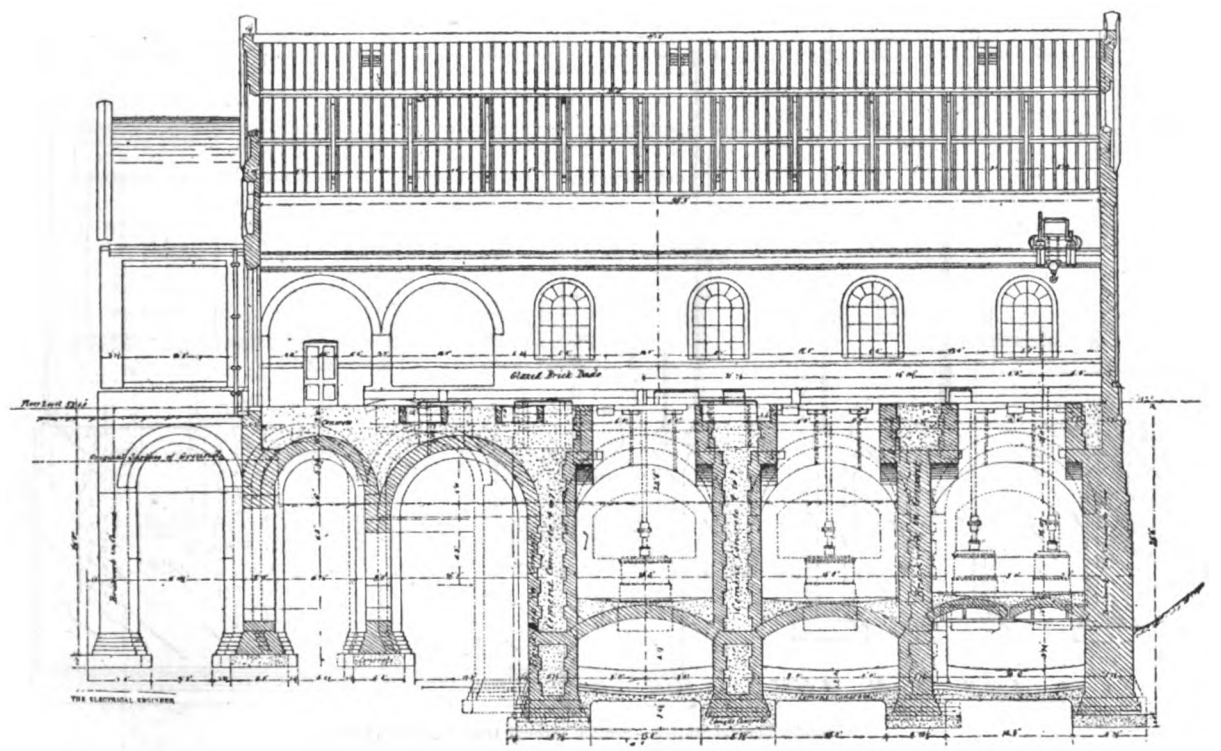
mittee then requested Mr. Oswald R. Swete to ascertain the probable demand for electric light. As a result, applications for the equivalent of 14,000 10-c.p. lamps were obtained. Reassured in this manner, the Council in

Digitized by Google

November, 1891, invited tenders for the construction of works to supply current to 12,000 10-c.p. lamps. The question as to what system should be adopted led to a contest between the partisans of the different methods, but the Council declined to accept a motion in favour of the storage system, and resolved to leave the matter open to those who tendered. The tenders, of which 15 were sent in, were referred to Mr. W. H. Preece, C.B., F.R.S., to examine and report. Eventually Mr. Preece recommended the acceptance of the tender of the Brush Electrical Engineering Company, Limited, for a combined steam and water power plant, at the sum of £21,005, with additions for buildings, street-lighting, etc., not covered by the tender, amounting to £19,970. The system proposed by the Brush Company was alternating, and the water power was originally intended to be obtained from the Severn near Diglis weir. This report was endorsed by the Watch Committee, but on its coming before the Council in April, 1892, the opposition to the alternating-current system, and in favour of a storage system, was so strong, that the committee's recommendation was not carried; but a motion was adopted in favour of printing the two lowest tenders for the Council's information. The controversy between the advocates of the two systems was the chief subject of discussion at meetings of the Watch Committee, but at the Council meeting on June 14, 1892, the opinion in favour of the alternating current had so far advanced that the Council affirmed the desirability of accepting the tender of the Brush Company, delaying its actual acceptance for further enquiry as to whether water power should be employed as an auxiliary to steam power. Obstacles placed in the way by the Severn Commissioners resulted in the abandonment of the proposal to use the Diglis weir for motive-power purposes.



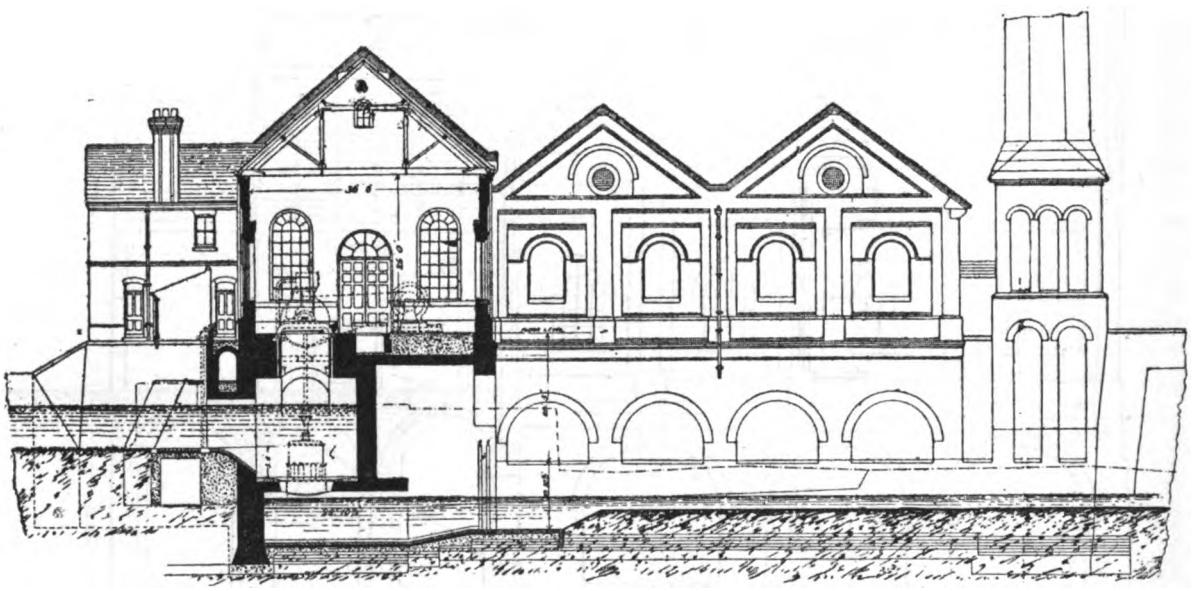
Worcester Central Station.—Elevation of Engine House and Transverse Section of Boiler House.



Worcester Central Station.—Longitudinal Section of Engine House, showing Wheel Pits.

Digitized by Google

It was then suggested by the late Mr. S. G. Purchas (who at that time was engineer to the city), ably seconded by his assistant, Mr. Thomas Caink, A.M.I.C.E., that the Corporation should negotiate for the purchase of the water power available on the River Teme at Powick. As a result of careful observations and measurements made by Mr. Purchas, it was found that this power could be relied upon to yield an average of 850,000 effective horse-power hours per annum. This fact, together with the data embodied in a report which was submitted to the Watch and Lighting Committee by their engineer, led them to recommend the purchase of the Powick Mills and to adopt the revised scheme submitted by the Brush Company. The Council, adopting this suggestion, resolved in December, 1892, to acquire the mills for £5,000. Mr. Purchas, in conjunction with Mr. Caink, subsequently got out the plans.

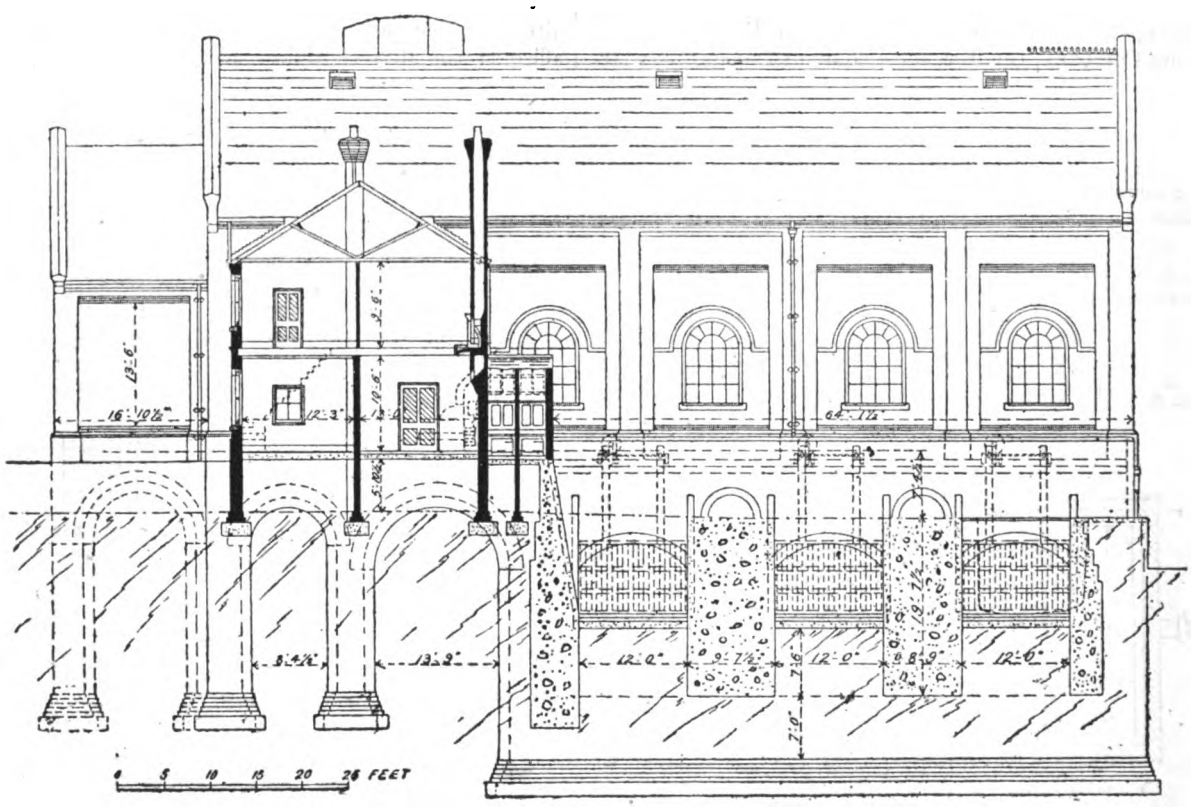


Worcester Central Station.—Longitudinal Section of Wheel Pits and Stream.

The Adopted System.

At the same meeting the Brush Company's revised tender was accepted, comprising a combined steam and water plant to the aggregate capacity of 400,000 watts, with an additional 60-h.p. turbine and alternator, and the mains, etc. In consequence of the great difficulty experienced in securing a good foundation for the generating station buildings, the cost was found to be much in excess of the sum originally named; but in August of last year the Council accepted the tender of Mr. Thomas Rowbotham, of Coventry-road, Birmingham, to erect the generating station at Powick Mills for £14,797.

Thus the novel features of the system consist in the combination of the water-power plant and steam-engines and alternators, the like of which is not to be found in any other town in this country. Mr. W. H. Preece was retained to supervise the work connected with the generating plant and mains, and Mr. Leonard Wigan, A.M.I.C.E., was appointed clerk of the works. Shortly afterwards the work of erection was commenced. Another matter closely connected with the scheme was the proposal to utilise electric motors for pumping at the municipal waterworks. This plan, it was submitted, would provide a means of using the water power at Powick during the daytime, when the demand for current in the city was low. The Council



Worcester Central Station.—Section through Offices and Head Race.

Digitized by Google

adopted this view, and voted £2,089 for motors and other machinery and the extension of the mains.

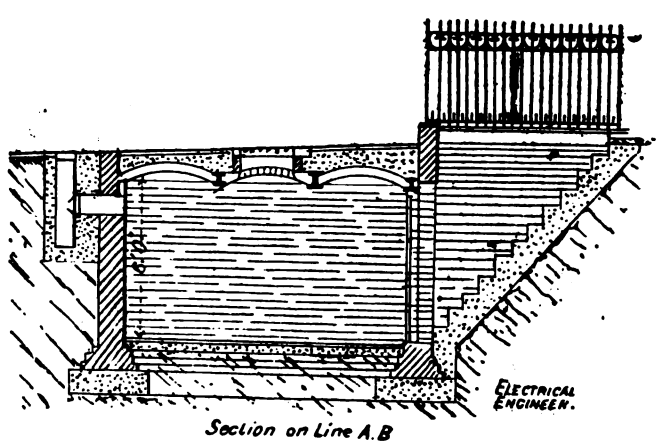
Worcester Central Station.—Plan of Main Transformer Station.



Worcester Central Station.—Section of Main Transformer Station at All Hallows.

The Site.

The site of the electricity works, as shown on the accompanying plan, is on the River Teme, just above Powick Old Bridge, and two miles distant from the centre of the town. In this connection it is interesting to note that water power has been utilised at this spot for many centuries. In Doomsday Book mention is made of two mills at Wick belonging to the Bishop of Westminster. The mills were situated on Langherne Brook, which flowed into the Teme immediately below the bridge. They remained in the bishop's hands until 1290, when Bishop Godfrey Giffard presented them to the Abbey of Malvern, to which they belonged till the dissolution, when they passed into the possession of the Crown. About this time was cut the channel which conveys from the Teme to the mills, joining the Langherne Brook a short distance above the mills. This gave rise to dispute between the owners of the mills and the persons through whose land the channel passed.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
ther Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIII. of new series of "THE ELECTRICAL ENGINEER" can e had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

CENTRAL-STATION STEAM-BOILERS.

We must confess that it has long since passed our comprehension why the water-tube design of steam-boiler should ever have obtained not only such an *extensive*, but in many cases also such an *exclusive*, use in the generation of steam for electricity works. Again and again have the deficiencies of this type been pointed out in these pages, while at the same time admitting its good points. No one would care to claim a special amount of engineering skill or wisdom in taking this position: it is a matter of ordinary common sense based on admitted fact. Yet consulting engineers and contracting firms, or whoever it may be upon whom rests the responsibility of designing central stations, have persisted in relying wholly upon water-tube boilers for the steam supply to these stations: and even at the present time, after some considerable experience has been gained in their working for this purpose, it is only in some of the provincial towns and cities, where local boilermakers obtain preference for their manufactures, that the single or double flue cylindrical boiler is adopted without question.

Granted at once that for quick steam raising the water-tube boiler easily takes first place, it does not follow by any means that this quality is the most fundamental one to consider in designing a central station. Of what possible good is it to the engineer in charge that he should be able to raise steam in half an hour or less to full pressure in a water-tube boiler, as against a longer period in the Lancashire type, when a sudden overload comes on through fog or other reasons in less than five minutes? There is no steam space worth talking about in a water-tube boiler: and probably a fifty per cent. overload above normal output would empty the boilers of steam, and run down the pressure to a point at which regular engine running is impossible, before a reserve boiler can be brought up to full pressure. A Lancashire boiler, on the other hand—although it takes more time and coal to get up a full head of steam—does not waste the heat energy spent on it thus: it is as good a thermal store as any yet devised, and will stand sudden demands for a length of time amply sufficient to get up steam in reserve boilers, especially if these be of the water-tube type.

Herein, therefore, lies to our mind the true and profitable employment of both kinds of boilers. We do not for a moment expect or wish to avoid the use of water-tube boilers. They have, as already stated, at least the one very great advantage which alone is enough to secure its adoption. But it is not as the "stock" boilers that they will serve best; they ought more especially to be the "stand-bys" or reserve. Of course, a great amount of scope is left in practical everyday working to the skill of the engineer in charge, though he cannot anticipate sudden overload arising from fog, and must simply scramble through it as well as he may. But it is absurd to expect heavy demands for electric energy to be met by boilers of such small storage capacity as those of the water-tube type, even although a reserve boiler can be introduced on very short notice.

A quarter of an hour's interval in the lighting

Digitized by Google

supply is a *hiatus valde deflendus* by shareholders and consumers alike: yet it is not only the most probable thing that might happen, but has actually occurred more than once in the Metropolis, too, of all places. The injury thus done to electric lighting is almost incalculable, for in many cases a sufficient amount of confidence has otherwise grown up in the warehouses, offices, banks, shops, and private houses to cause reliance entirely upon electric lights rather than gas. A breakdown, even for ten minutes, is therefore a matter of enormous importance when everyone requires light for private purposes and the street lamps must also be kept going.

Suppose Lancashire boilers are used for normal working, in case of a sudden call for double the current—such as often happens in winter when a fog comes on—there is, or should be with careful stoking, amply sufficient steam storage for a length of time which will allow not only reserve boilers under easy steam to be fired up to full pressure, but also those of the water-tube type to be brought into service even from a cold condition. By this time probably the demand may have become slightly easier, but at any rate there is breathing space enough to take prompt action.

If those whose duty it is to decide upon such points should cause the exclusive adoption of water-tube boilers for central-station work in the future, we should feel inclined to say that they are courting endless trouble and annoyance, not only for those who own the electricity works, but also the unlucky consumers depending upon it for light or power.

REVIEWS.

The Telephone Handbook: By HERBERT LAWS WEBB. *Electrician* Publishing Company, Chicago. Price 1dol.

This is a small handy book of nearly 150 pages, and like all Mr. Webb's work is carefully done. It is what it professes to be—"a practical book on telephone working and management," as exemplified by American practice. A brief *resume* of telephonic discovery is followed by a description of the various pieces of apparatus generally in use, of wiring, of batteries, and of methods of exchange working. The text is illustrated as required, and the information is reliable and of just that character that the ordinary worker requires. In form it is well within the capacity of the ordinary reader, hence should be extensively read. The practice in England is not altogether on all fours with that in America, so that the work will hardly appeal to so large a class of readers here as there. Mr. Webb is to be congratulated upon the care and industry he has shown in the preparation of this book.

Electric Lighting Plants.—Their Cost and Operation: By W. J. BUCKLEY. Wm. Johnston Printing Company, Chicago. Price 2dols.

This book is more of the nature of a price-book—and such we should term it on this side—than as belonging to any other class. The larger part, therefore, is of more interest in America than here, because the prices given are those which rule in that country. The smaller part, however, appeals to all users of electric lighting plant, and some portions are exceedingly interesting to both users and manufacturers wherever they may reside. It is interesting to know that "of the operating stations 12·6 per cent. are losing money; with 10·8 per cent. the receipts barely cover the running expenses, while 76·6 per cent. are making money ranging from two to fifty-one per cent. yearly on the undertaking." That being so proves electrical supply to be a good sound commercial investment. Another important question wherein we quite agree with the author, is in the employment of a "capable consulting engineer." Such employment "will not only prevent expensive mistakes, but frequently effect a saving in operation of many times his commission." The introductory suggestions as to size of building are also good. After this introductory matter, we get the cost of coal, labour, etc., in producing motive power, a list of boilers, method of setting, prices, efficiencies, etc., and information of a similar nature as to chimneys, to engines, dynamos, shafting, belting, dynamos, and other parts of a central station equipment. The explanatory curves are numerous, as are the tables. Of course, as above stated, these prices must be corrected for English apparatus.

THE ELECTRICITY WORKS AT WORCESTER.

(Continued from page 425.)

Some of the most severe fighting in the battle of Worcester took place there, the mills being held by the Royalist sharpshooters, from which they commanded the bridge, and these were only dislodged by firing the mill. The only relics of the battle found are two clay pipes and a cannon-ball, which were picked up in the excavations for the foundations of the generating station buildings. When the Corporation purchased the site there existed three mills—a corn-mill on the east with two wheels; a mill in the centre with two wheels which for the last century and a half have been used to grind the material for the manufacture of the famous Worcester china, from whence it is carted to the factory in Worcester; on the west is another mill with three wheels, known as the "forge mill," this having been used in former times as a forge, the iron being brought up by water.

The Station Buildings.

The Corporation pulled down the East Mill and built the engine-house on the site, the boiler-house being arranged along the bank at right angles to the former. The external dimensions of the engine and dynamo house, of which plans and elevations are given herewith, are 102ft. long, 42ft. wide, and 40ft. high. The floor level is 36ft. above the foundations, being 3in. above the level of the highest recorded flood. The engine-house is supported upon arches springing from four parallel walls forming the piers and abutments of the turbine races, 5ft. 7½in. thick above the footings, consisting of an outer casing of brickwork, 1ft. 1½in., with a core of concrete 3ft. 4½in. The whole of the brickwork and concrete up to the floor line is built in Portland cement. Two of the turbines are fixed on stone seatings supported by a brick arch, the turbine-pits being 16ft. wide. The other two turbines are arranged in one pit, the width being 17ft. These are fixed on stone seatings resting upon two small brick arches, the whole being carried on cast-iron girders, as there was not sufficient room to carry them entirely on brick arches, as in the other two cases. The small turbine is 30in., and the large one 40in. The other two water-motors are each 54in.

The maximum difference between the head and the tail race in dry weather is nearly 12ft. The normal working head is 10ft., and in very dry weather 11ft. 6in. The water is conveyed to the engine-house by a channel about a quarter of a mile long and 30ft. wide, there being, under ordinary circumstances, 8ft. of water in the channel.

The Boiler-House.

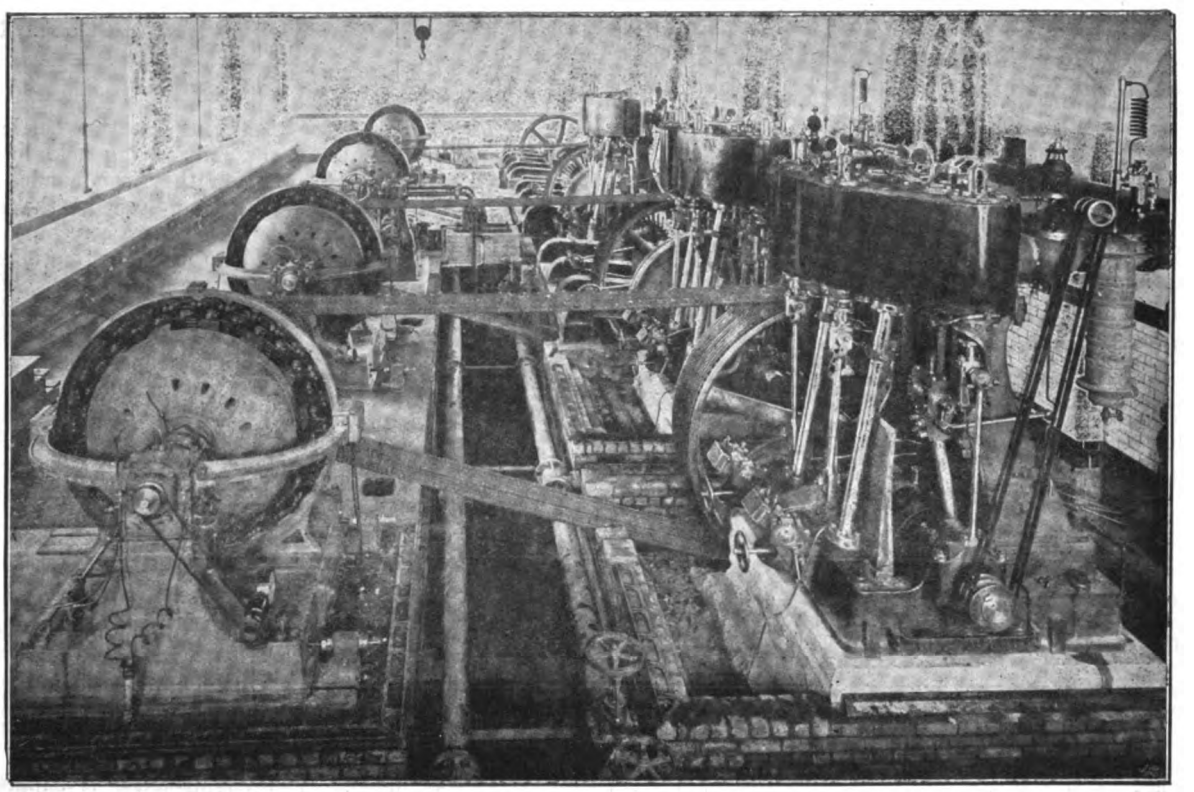
The boiler-house is 44ft. wide and 72ft. long, the chimney, 160ft. high and 7ft. 3in. internal diameter, occupying the ground between the boiler-house and the main road. As will be seen, there is ample provision for additional boilers.

Digitized by Google

Coal will for the present be brought to the works by road. Eventually, however, it is probable that the Corporation will have the Teme dredged, so that barges may be brought up the river and coal discharged direct from the barge into the boiler-house.

The engines are supplied with steam from four 124-h.p. Babcock and Wilcox water-tube boilers arranged in two batteries. Each boiler has a heating surface of 1,411 square feet, with a grate area of 26½ square feet. The drums are 36in. by 23ft. 7in. long, and are provided with two stop-valves, one dead-weight safety-valve, and all the latest improvements. The boilers are constructed for a working pressure of 120lb. per square inch, and are easily capable of evaporating 4,000lb. of water per hour. The firing is done by hand.

The main steam-pipe, which is arranged in ring form, is of wrought iron 6in. in diameter, having valves so arranged that any portion may be easily isolated without interfering with the working of the engines. The branches from the main pipe to the engines are 4in. in diameter. The valves



Worcester Central Station.—Internal View of Engine and Dynamo Room.

are of the parallel slide type, which allow of a clear open passage for the steam. Water separators are provided in the main steam-pipe as well as on each engine, which are drained by Geipel's expansion steam traps. The exhaust piping, which is of cast iron, is 7in. in diameter, each engine exhausting direct to the atmosphere. The contractors did not consider it advisable to put down condensers, although abundance of water is at hand. There are two feed pumps, of the duplex type, 6in. by 4in. by 6in. stroke, one of which is illustrated. Each pump (which has been made by the Smith and Vaile Company, and supplied by Mr. F. Nell, of Mark-lane, E.C.) is capable of supplying 2,500 gallons of water per hour. They are arranged to pump direct from the river or from a feed tank, which is heated by the exhaust steam from the feed pumps. The feed pipes, which are of galvanised wrought iron, are also arranged on the ring system, being provided with suitable valves for isolating any section. These pumps are also utilised for drawing water from the Teme into the tank for supplying the water service throughout the buildings.

The Steam-Engines.

The steam motors comprise three main engines, each capable of developing 286 h.p. They are of the well-known Brush compound vertical type, having cylinders 15in. by 25in. by 16in. stroke, and run at 167 revolutions per minute. The high-pressure cylinders are provided with piston valves, and the low pressure with ordinary slide valves.

The steam is controlled by means of highly sensitive equilibrium governors, and the low-pressure slide valves are provided with Hackworth gear for varying the cut-off in the low-pressure cylinder whilst running. One engine is fitted with a grooved flywheel for driving one of the alternators; the other two are provided with disc couplings for connecting each engine to another shaft which carries the grooved pulley for driving the alternators, this arrangement being made to allow of their being driven either by the engines or turbines.

The engine-room is equipped with an overhead traveller, made by Messrs. R. C. Gibbins and Co., of Berkeley-street, Birmingham, and a view of the crane is given. The crane is made for lifting 12 tons, 35ft. 8½in. span. The main beams are rolled-steel plated girders, and are bolted to strong castings at each end. The crab has single and double purchase lifting gear, lifting its full weight with return chain and block, which can be detached if required, thus giving the crane four speeds of lift. It is fitted with powerful lever brake and transverse travelling gear. The longitudinal travelling gear is fixed at the end of the crane, and is arranged to be worked either single or double purchase. This traveller has proved of great service in the laying down of the whole of the machinery.

The Turbines.

We now come to the first novel feature in this station—namely, the use of turbines. Special interest is attached to the ingenious method of working these motors. They are "cylinder gate" Victor turbines, the installation having been designed and carried out by Mr. Frederick Nell, of 16, Mark-lane, E.C. Annexed are illustrations of the turbine, head gate, and governor used. Two of the turbines are 54in., capable of developing 211 h.p. when working under a fall of 12ft., and using 11,700 cubic feet of water making 75 revolutions per minute. These two turbines are arranged side by side with two of the 15in. by 25in. by 16in. steam-engines, and are geared to the grooved

Digitized by Google

pulleys by means of clutches. These clutches, known as Snyers, may be roughly described as "brushes and combs." They are of a divided disc form, the one half carrying a number of steel brushes, and the other half having teeth, or a comb-like arrangement. The brushes are caused to grip the teeth, and so form a mechanical clutch. There are also one 48in. turbine capable of giving 162 h.p. when working under a fall of 12ft., and using 8,950 cubic feet of water and making 84 revolutions per minute; and one 30in. turbine capable of developing 62 h.p. under a fall of 12ft., and using 3,450 cubic feet of water and making 134 revolutions per minute. These two turbines are placed side by side, so that either or both of them can be coupled by means of mill clutches to the grooved driving pulley. By this arrangement during times of low water the small turbine may alone be used, so that the best efficiency is secured, while, when there is sufficient water, the full output of the alternator—namely, 125 kilowatts—may be obtained by using both turbines. Similarly, when the water power is insufficient for the whole of the turbines, it is, of course, possible to reinforce that power by running the steam-engines in conjunction with the turbines of the respective alternators. Each turbine is provided with an automatic governor for regulating the speed. There are three sets of sluice-gates, 12ft. by 8ft., and arrangements for keeping back floating matter from the turbines. The gear for transmitting the power from the turbines to the driving pulley comprises two bevel-teethed wheels, the larger wheel having wood teeth, being fixed at the top of a vertical shaft, on the bottom of which the turbine wheel is fixed. The working of the wood teeth is almost noiseless.

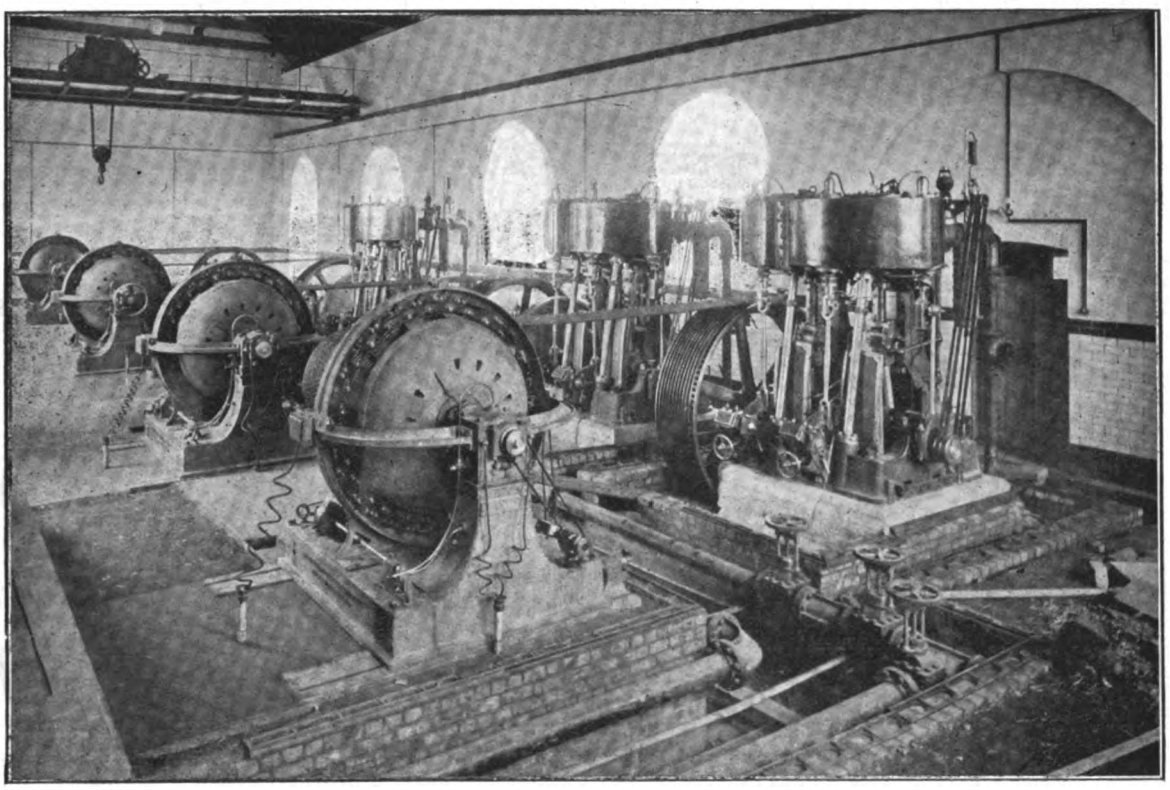
The Alternators and Exciters.

The four alternators, which are of the well-known Mordey-Victoria type, are driven from the above engines and turbines by means of 10 separate cotton ropes. Each machine runs at 430 revolutions per minute, and has a capacity of 58 amperes, the working pressure being 2,200 volts. The armatures are stationary, and the field magnets revolve. The lubrication of the bearings is automatic, being effected by means of small pumps, which keep up a constant circulation of oil.

The exciting plant comprises two Brush-Victoria dynamos, each having an output of 5,830 watts, and driven by means of leather belts direct from pulleys keyed to the shafts of two of the alternators, and a Brush-Victoria dynamo having an output of 6,500 watts. The latter machine is coupled direct to a 7in. by 6in. vertical Brush engine, mounted upon a common bed-plate. This latter is capable of exciting all the alternators, and in this way ample provision is made to meet both full and day load requirements economically.

The Switchboard Arrangements.

The well-known switch-pillar method devised by Mr. J. S. Raworth, and which we described some time ago, has been introduced into this station. Each alternator is controlled by its own switch pillar, which contains a system of interlocked switches which make it impossible for the attendant to close the main circuit before the field circuit is closed, and likewise when the main switch is closed the field switch is locked and cannot be opened before the main switch. These switch pillars are built entirely of cast iron, and include also the main ammeter, the field ammeter, synchroniser switch, and a pair of high-tension fuses.

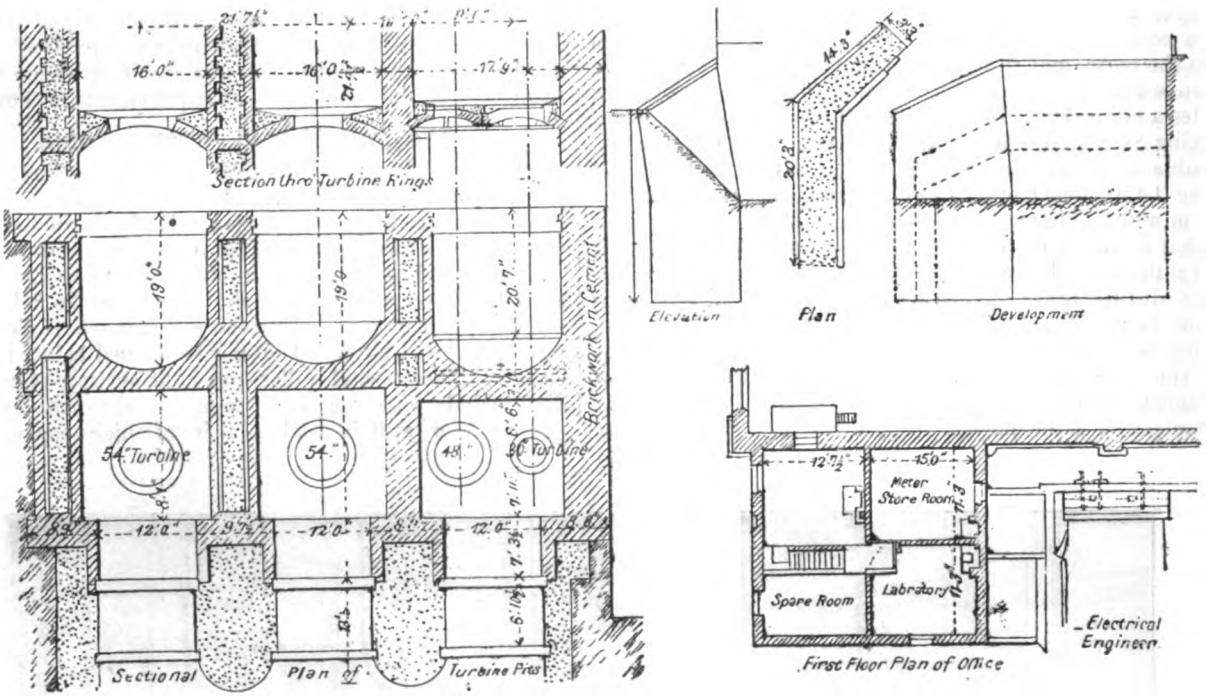


Worcester Central Station.—Internal View of Engine and Dynamo Room.

Underneath each pillar is placed a rheostat for compensating the change in resistance of the field circuit due to temperature variations. The current from the alternators passes through these pillars on to the main station omnibus bars, one of which runs direct from the pillars to the circuit-boards, the other being led to the main ammeter-board, on which are also fixed the lamps and switches used for synchronising. Switches are provided on this board for shunting the main ammeter when required. From this board the outer main is led through the registering meters to the circuit-boards. At present there are only two circuit-boards fixed, each containing a main ammeter and double-pole high-tension switches and fuses. The synchroniser and circuit-boards consist of polished marble slabs mounted in handsome wood frames. The whole of the high-pressure switching arrangements are grouped together and operated from a platform about 3ft. above the engine-room floor. Each exciter is controlled by one of the Brush Company's latest type of exciter pillar. This contains Raworth's switch for automatically closing and opening the circuit of each exciter according as its E.M.F. is sufficient for supplying the circuit, so that to switch an exciter into circuit it is merely necessary to open the steam stop-valve, while it is switched

Digitized by Google

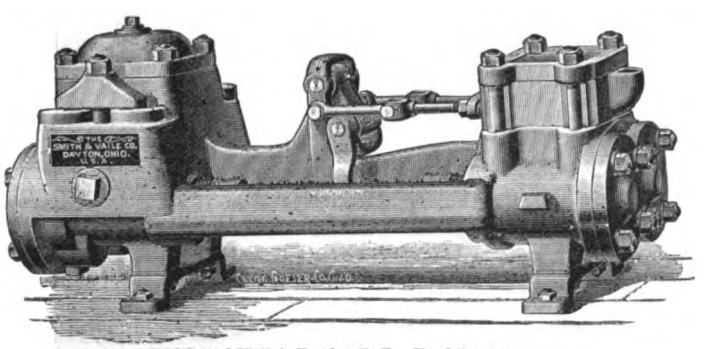
out of circuit by merely shutting down the steam. Each pillar carries an ammeter and voltmeter for regulating the exciters. The rheostats are grouped together and fixed on the switch platform under the main station voltmeter, the exciter pillars being fixed close to their respective exciters.



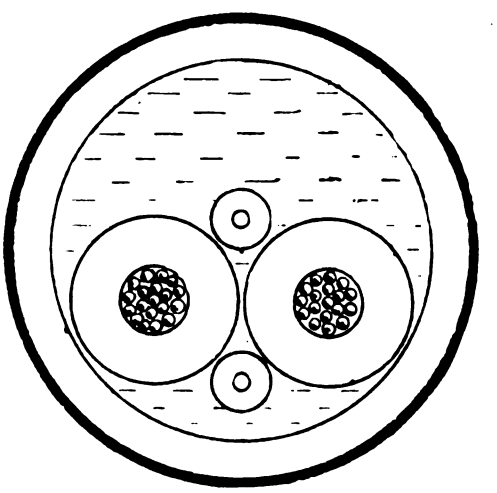
Worcester Central Station.—Sectional Plan of Turbine Pits.

Method of Distribution.

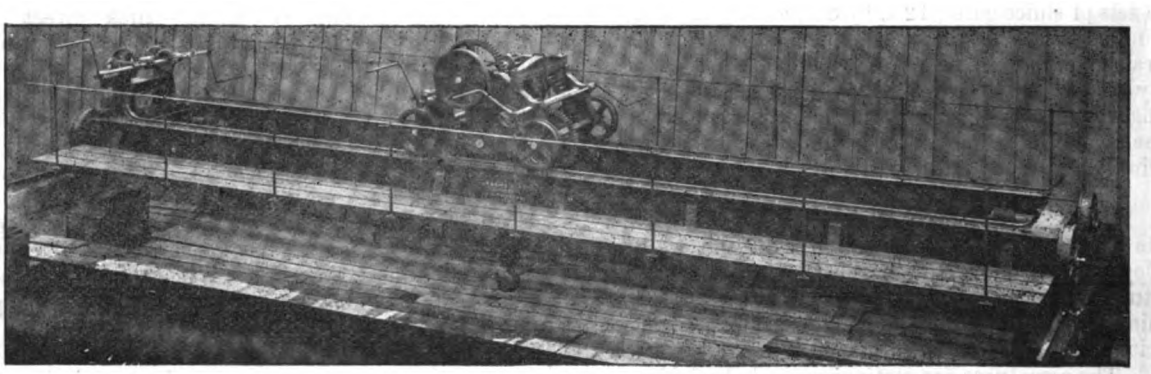
The main feeders from the generating station at Powick are laid underground, and are led to the high-pressure distributing sub-station at All Hallows, a plan and section of which are subjoined. These main feeders are laid on the Brooks system of oil insulation, which method has proved so satisfactory at Chatham, Rochester, Keswick, and other places, where it has been in use for some years. These feeders consist of three heavy wrought-iron tubes, the metal having a minimum thickness of ·25in., and an internal diameter of 2in. The conductors drawn into two of these tubes are made up of two $^{19}/_{14}$'s and two pilot wires, laid up together into one cable, the remaining tube being left spare. A section of the tube and conductors is annexed. Special joint and junction boxes are placed at various points along the line, from which branch connections may be taken as required. Midway along the line an oil pressure tower, which is illustrated herewith, has been erected, this allowing for expansion and contraction (due to variations in temperature) of the thick heavy insulation oil. During the laying, a very careful test was kept on the cable, and they were



Smith and Vaile's Duplex Boiler Feed Pump.



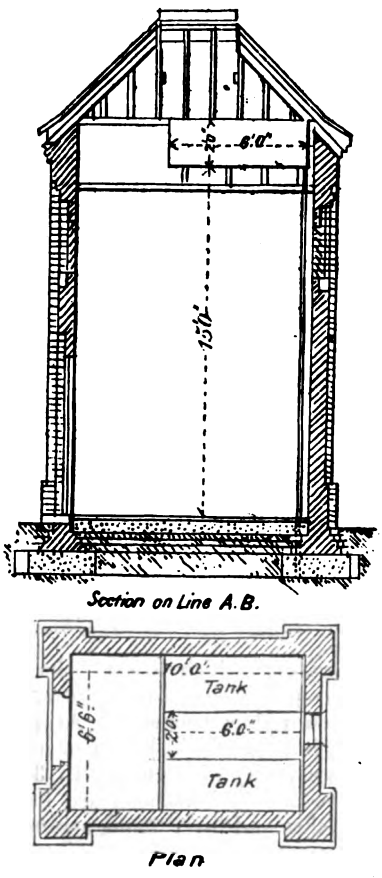
Worcester Central Station.—Section of Main Feeder from Powick to All Hallows.



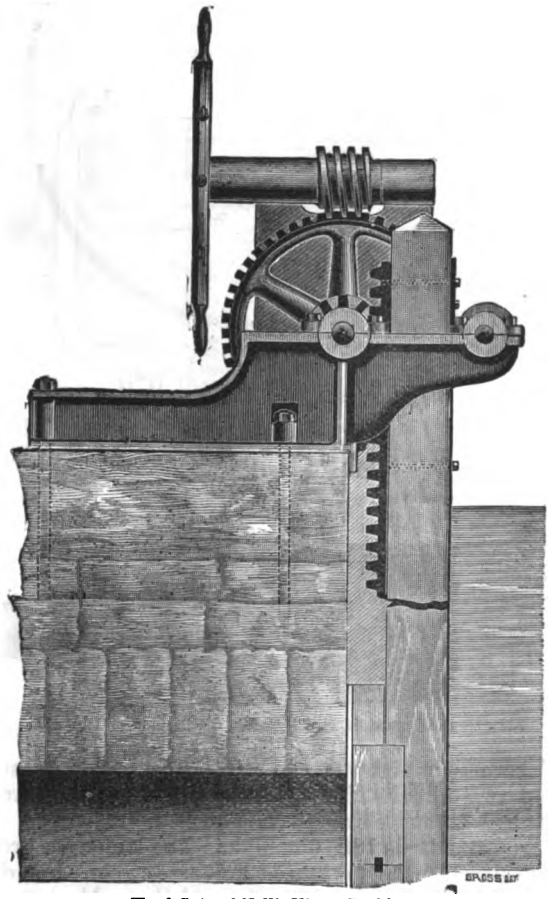
Worcester Central Station.—Side View of Overhead Traveller.

Digitized by Google

finally flashed with double the working pressure—namely, 5,000 volts. The contract for the supply and laying of these feeders was given to Messrs. Johnson and Phillips,



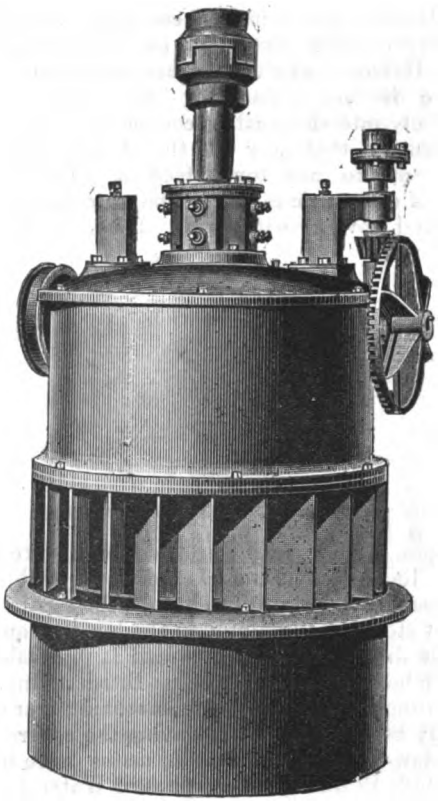
Worcester Central Station.—Section and Plan of Oil Tower at St. John's Green.



Head Gate of Nell's Victor Turbine.

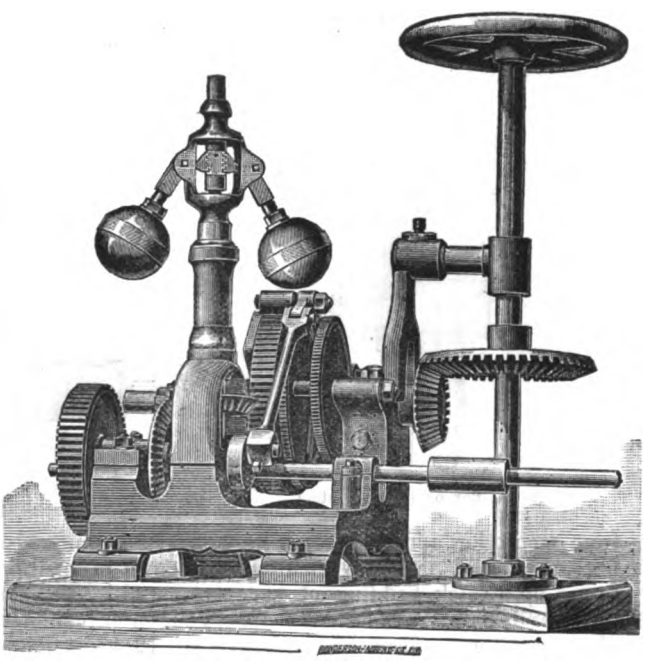
of London and Charlton, who are the sole makers of this system, which there is little doubt will be more generally used.

A few further remarks, which by the aid of the accompanying illustrations of the mains, junction and terminal boxes, and house service boxes, will be rendered more explicit, will be interesting to those who have not investigated the Brooks system of oil insulating mains. Although the above-mentioned tubes are 2in. in diameter, they may in other cases be less, often not exceeding an inch bore, and bare copper wires can be laid through the



The "Cylinder Gate" Victor Turbine.

tubes with only a slight serving of yarn to keep them from actually touching one another. The guttapercha or indiarubber insulation, which in the ordinary way would be given to the conductors, is here replaced by a thick viscid oil. It is injected into the tubes after the conductors have been laid, so as to fill up all the spaces completely, from a portable cauldron. By this means



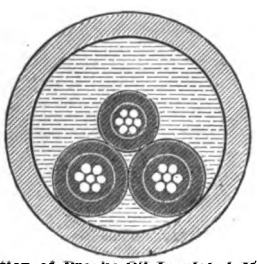
Nell's Victor Turbine Water Wheel Governor.

the temperature of both wire and oil is raised to about 360deg. F., so as to drive away any moisture from the covering. The boxes at which the oil is thus forced into

Digitized by Google

the mains are situated usually about 100 yards apart, and are made of malleable iron, with screw-covered lids. The operation of splicing consists simply in jointing the separate wires of the cable ends, and slipping over them a neat sleeve of insulating material to keep them apart, after which the hot oil is poured in and the cover screwed down. The makers state that the Brooks system of oil-insulated cables is cheap, and that it affords a permanent and reliable insulation.

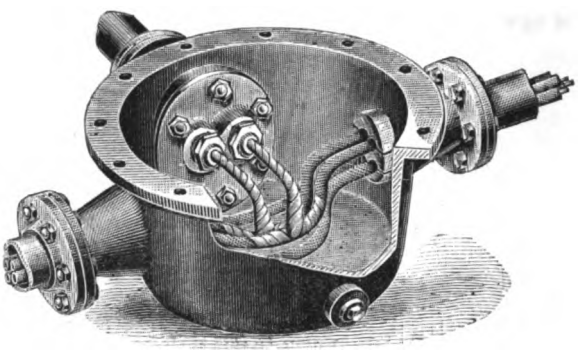
As already mentioned, these main feeders terminate at a circuit-board fixed in an underground chamber at All Hallows, where they are connected to the high-pressure feeders, circulating throughout the city by means of interchangeable connectors, the latter being so arranged that any of the Brooks mains may be thrown on to any town feeders. The town feeders consist of concentric cables insulated with specially-treated paper and covered with lead. They are drawn into cast-



Section of Brooks Oil Insulated Main.

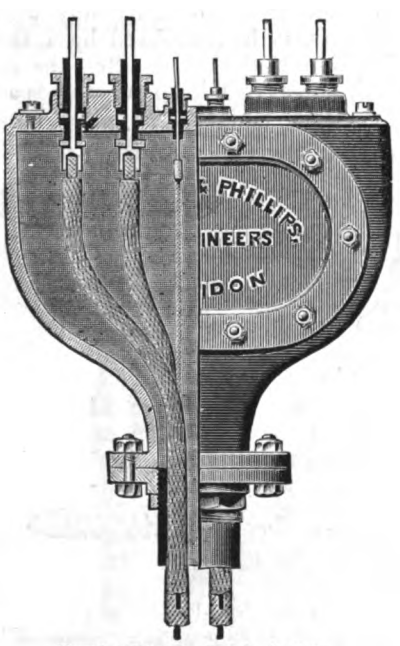
iron pipes. These mains are laid on a system devised by Messrs. Raworth and Geipel, and which enables any of the high-pressure feeders to be shut off for repair or extension without stopping the supply in the low-tension distributors. Suitable draw-boxes are provided at intervals, and special junction-boxes designed by the Brush Company are used for jointing; the joints, being mechanical, are easily made and may be inspected by removing the cover.

The low-pressure distributing mains have been made by Callender's Bitumen, Telegraph, and Waterproof Company, Limited, of London and Erith, and have been laid under the supervision of Mr. Moir, the Callender Company's resident engineer at Birmingham. The mains consist of concentric cables, with each of the conductors insulated from each other and from earth by means of a bitumenised fibre, then lead sheathed with a heavy cover of lead, protected by a thick bedding of yarn, armoured by two steel tapes, and double yarned over all. The outer conductor of these cables is formed in each case of 19 wires divided into two segments, so that it is possible to cut into the cable and tap on to the inner strand without absolutely destroying the continuity of the outer conductor. These cables are laid direct in the ground, as they require no protection other than that afforded by their own armour. The sections used are ·10, ·15, ·20 of a square inch. They have been made specially for the work in such lengths that they will reach without joint between two sub-stations, thus making an unbroken network. There is, therefore, no fear of any faulty connections on the distributors. These low-tension mains are laid on both sides of High-street, the Cross, Foregate, and Broad-street, and on one side of College-street, Bridge-street, and St. Nicholas-street. Orders have already been given for extensions in Sansom-street, Mealcheapen-street, Sidbury, and in St. John's. A number of consumers have already been connected with the mains, and the work of connection is being carried out by the Callender Company's men, under the direction of Mr. Davenport.

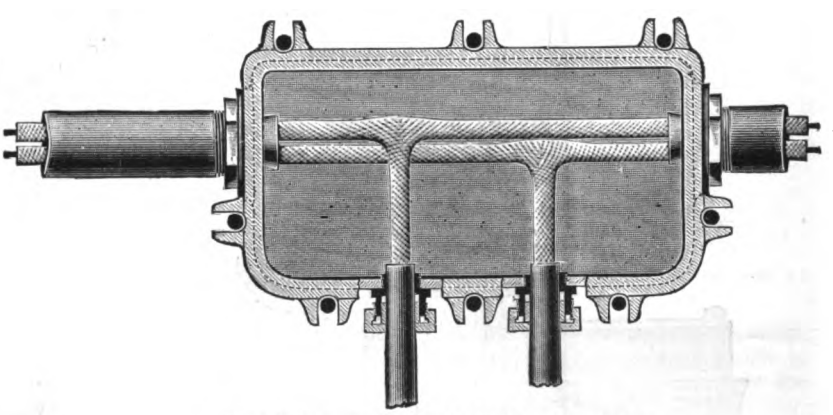


Junction Box on Brooks System.

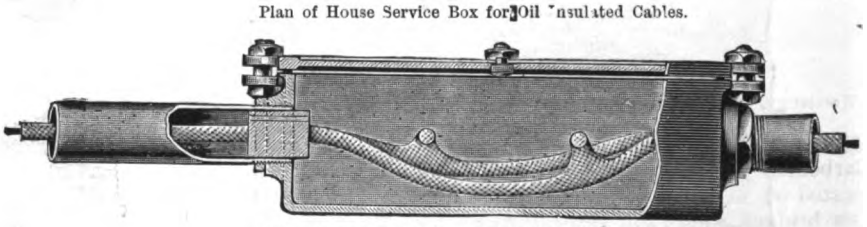
The transformers, which are of the Mordey-Victoria type, are mostly placed in sub-chambers, either under the pavement or on public property. At present there are seven of these, in each of which two or three transformers are placed of a capacity of from 24 to 36 kilowatts. At these points the current is transformed from 2,000 volts to 100 volts, switches and fuses being arranged on both sides of each transformer for throwing into and out of circuit without affecting the continuous supply of current. In the outskirts of the city it has not been thought advisable to lay low-tension mains; but as the high-pressure feeders are so easily laid, and at a comparatively small cost, the Corporation have had no hesitation in supplying customers in such districts by means of isolated transformers.



Terminal Box on Brooks System.



Plan of House Service Box for Oil Insulated Cables.



Elevation of House Service Box for Oil Insulated Cables.

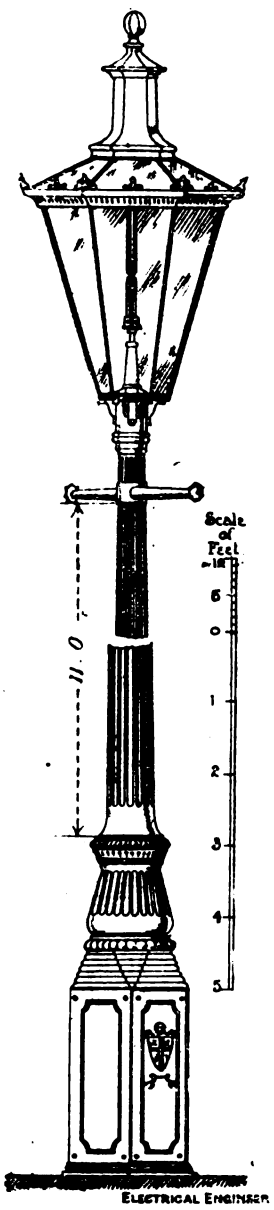
The public lighting comprises 27 arc lamps, supplied from two circuits from All Hallows. These lamps, of which a corner elevation is annexed, are carried mostly on iron standards 18ft. 6in. high. The lamps are erected in High-street, the Foregate, Foregate-street, Broad-street, St. Swithin's-street, and in the old Corn Market. These thoroughfares constitute the principal streets. The lamps are Brush 15-ampere double-carbon lamps, fitted to ornamental posts and brackets, and enclosed in japanned copper hexagonal lanterns. The lamps are worked off a separate

Digitized by Google

main divided into two circuits; the conductors consisting of concentric cables, insulated with pure and vulcanised india-rubber, taped and compounded, and drawn into galvanised iron pipes. These mains are connected to small transformers specially designed to fit into the bases of the lamp-posts. Each lamp has therefore been provided with its own independent supply, and can be turned on and off without in any way interfering with any of the others. The lamps are arranged on alternate circuits, so that half the lamps may be switched out after midnight by opening one of the switches at All Hallows.

Electric Pumping Plant.

The idea of pumping the city water by means of water power, as about to be exemplified at the waterworks, is not new for Worcester, as it was pumped in this manner



Worcester Central Station.—Corner Elevation of Brush Arc Lamp Standard.

at least 200 years ago. In 1794 the new waterworks at Barbourne were completed. The old waterworks were located on an island in the Severn, between the old and new bridges, where the Severn water was pumped up to the reservoir in the centre of the town by a waterwheel driving a pump. This waterwheel was, of course, driven by the water of the Severn, but it does not appear to have given universal satisfaction, as Wash, the historian, writing a few years later, says of it: "Lately, a machine has been erected and pipes laid to convey the river water to every part of the town, although this, like other public works, has not been conducted with the greatest frugality, or in the best manner. The wheel at the waterworks was at first too small, which, being afterwards enlarged, renders it too great for other parts of the work. The reservoir would have been better placed near the and at the head of the pipes, and some think that the bore of the pipes and the pumps are not in due proportion. In floods or low water (especially the latter) there is not the quantity of water thrown into the town that there ought to be." The water-engine was abandoned in 1807 in favour of a fire-engine, which was to be of sufficient power to pump 126,000 gallons to a height of 70ft.

However interesting this historical fact may be, even greater interest will be excited in the laying of a main from the generating station to the municipal waterworks for the operation of electric pumping plant by means of alternating-current motors. Here the electrical energy brought by the high-pressure mains is transformed by means of two 30-kilowatt transformers to 100 volts, at which pressure the motors are arranged to work. There are two three-throw horizontal plunger pumps, with rams 6in. by 15in. stroke, each set capable of pumping 10,000 gallons of water per hour against a vertical height of 300ft., through 5,000 yards of 10in. pipe, at a speed of 45 revolutions per minute. Each set is fitted with a second motion shaft, spur wheel and pinion, and fast and loose pulleys with striking gear complete. The pumps are placed side by side upon a strong cast-iron bed-plate of sufficient length to take the driving gear. Each pump is fitted with brass suction and delivery valves, glands, and stuffing-boxes bushed with brass. The pump rams are of cast iron, turned and fitted with guide shoes and steel pins. The two motors, which are of the Brown type, which has been largely adopted in Switzerland, are each capable of developing 30 b.h.p.; they are of the non-synchronous type, running at about 500 revolutions per minute.

Charges for Current.

The price for current will be at the rate of 5d. per Board of Trade unit for lighting, and 3½d. for motive-power purposes. The following discounts in respect of the consumption of electricity will be allowed: for an annual bill amounting to £25 and under £50, 3 per cent.; to £50 and under £100, 5 per cent.; and to £100 and upwards, 10 per cent.

The Corporation will lay the service line from the main to the meter, and, with the exception of the portion of the service line extending from the main to a point 10ft. within the boundary of the consumer's premises, or to the meter, if it be situated within that distance, will charge the consumer for the whole thereof. The portion excepted will be laid without charge to the consumer.

The charges to consumers for service line to supply 16-c.p. 60-watt lamps, or their equivalent, will be as follows: not exceeding 15 lamps for a distance of 50 yards, 3s. 6d. per yard; not exceeding 15 lamps for a distance of 100 yards, 3s. 10d. per yard; exceeding 15 lamps and not exceeding 20 lamps for a distance of 50 yards, 3s. 8d. per yard, etc. The meter and service switch will be supplied by the Corporation to the consumer on hire at rents varying from 4s. 6d. per quarter for 15 lamps to 12s. per quarter for 300 lamps.

Conclusion.

As mentioned early in this article, the Brush Electrical Engineering Company, Limited, have, with the exception of the erection of the buildings, carried out the whole of the undertaking, Mr. W. Geipel, their superintending engineer, having control of the work, assisted by Mr. S. A. Mahood, their resident engineer. The general supervision of the station has been in the hands of Mr. W. H. Preece, who had been aided by Mr. A. H. Preece, Mr. T. Caink (the borough engineer), and Mr. F. R. Davenport, whilst Mr. Leonard Wigan, A.M.I.C.E., has been clerk of works. To Messrs. Geipel, Caink, and Wigan, and others interested in the station we have to tender our thanks for their kind assistance in the preparation of this article.

The Worcester electricity works have been well designed and brought successfully to their present position, and both the contractors and the Corporation are to be congratulated upon the fact. There are about 10,000 houses in the city, and apart from the arc lighting, the central station commences with the satisfactory number of 4,000 lamps connected to the mains. Mr. T. Caink, whose portrait is reproduced at the commencement of this description, will

Digitized by Google

act as electrical engineer, and under his guidance the station promises well.

The supply of gas which is provided by the Worcester New Gaslight Company is sold at 3s. 7d. per thousand, with a discount of 10 per cent. on quarterly accounts paid within a month. At this rate, and bearing in mind the charge of 5d. per unit for current, the Corporation electricity works should prove to be a formidable competitor. In conclusion, two more interesting facts are worthy of record. One is that the lodge gates belonging to the Hon. A. Percy Allsopp, M.P., whose residence is situated four miles from the generating station, are opened and closed by electric motors energised from a main laid down specially for the purpose. The second fact is that applications for a supply of some hundreds of lamps have been received from Malvern, seven miles distant.

ELECTRICAL EXHIBITION.

In connection with the opening of the station, an electrical exhibition is being held in the Public Hall—it being opened yesterday afternoon. It will remain open until the 20th inst. The arrangements of the exhibition have been carried out by Mr. F. R. Davenport, who has been testing the mains. The exhibits include all kinds of electrical lamps, fittings, and appliances, electric motors, dynamos, engines, and other applications of electricity. The small hall is occupied by Messrs. Crompton and Co. with an exhibition of appliances for electric cooking, special demonstrations being given. The exhibitors include Messrs. Phillips, 175, Oxford-street, W.; Mr. J. F. Santouna, 34, Sidbury, Worcester; Messrs. F. and C. Osler, 100, Oxford-street, W.; Messrs. B. Verity and Sons, London; the Edison and Swan United Electric Light Company, Limited, London; Messrs. T. W. Scott and Co., 28, Broad-street, Birmingham; the Brush Company; the New British Installation Contractors, Limited, Worcester; the National Telephone Company, Limited; Messrs. Wyndham and Seward, 57, Oxford-street, Derby; and Messrs. John Cam and Sons, Shambles, Worcester.

CITY AND GUILDS OF LONDON INSTITUTE.

LECTURE V.—FORMULÆ AND EXAMPLES CONNECTED WITH OHM'S LAW.

(Specially contributed.)

I have referred to the various tables supplied by manufacturers. In almost every case the area of the conductor is given both in English and French measurements—the one in square inches, the other in square metres or square millimetres. In fact, all business men have now to familiarise themselves with both systems of measurement. Thus while our standard of length is the yard, that of the French is the metre. Our yard is 36in. long, the metre is 39·37in. This standard is divided into tenths, hundredths, etc.; the tenths are called decimetres, the hundredths centimetres, and the thousandths millimetres—thus:

One metre	= 39·37	inches.
One decimetre	= 3·937	,,
One centimetre	= ·3937	,,
One millimetre	= ·03937	,,

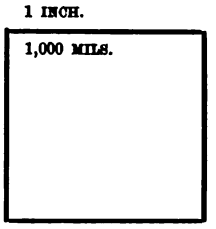
On the other hand,

One inch = 25·4 millimetres.
,, ,, = 2·54 centimetres.

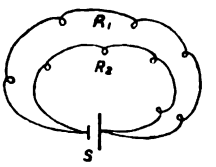
There is just one other measure I would mention now. It is called a *mil*, and is one-thousandth of an inch.

One inch = 1,000 mils.
One mil = ·001 inch.

This latter is an important measure, for many of our rules and regulations are based upon a current of 1,000 amperes per square inch as the maximum allowable; and as one square inch contains 1,000 × 1,000 square mils, this current gives one ampere to every 1,000 square mils. The greatest currents used are those in connection with electric welding. Thus for welding copper some 60,000 amperes per square inch of metal are required, which is 60 times the maximum allowed for lighting purposes.



It is seldom that resistances are in series, so that the total resistance of a circuit is seldom the sum of the separate resistances. Suppose we have a circuit with two



external resistances arranged as in the diagram: The total resistance of that circuit is

Internal resistance of battery + external resistance.

The external resistance is the joint resistance of the two resistances.

Call these resistances respectively R_1 and R_2;
the joint resistance R;
the internal resistance r.

Let us assume r to be so small as to be negligible

Now current C_1 through $R_1 = \frac{E}{R_1}$;

,, C_2 ,, $R_2 = \frac{E}{R_2}$;

and if total current = C,

then $$C = C_1 + C_2 = \frac{E}{R_1} + \frac{E}{R_2}.$$

If E = 1,

this becomes $$C = \frac{1}{R_1} + \frac{1}{R_2} = \frac{R_2 + R_1}{R_1 R_2}.$$

But current C is inversely as resistance R, therefore the total resistance R must be $= \frac{R_1 R_2}{R_1 + R_2}$.

If we have three parallel resistances, R_1, R_2, R_3, then the joint resistance is

$$R = \frac{R_1 R_2 R_3}{R_2 R_3 + R_1 R_2 + R_1 R_3}.$$

If there are n such resistances, then total resistance is

$$\frac{\text{Product of } n \text{ resistances}}{\text{Sum of products of resistances taken } (n-1) \text{ together}}.$$

Example.—Find the joint (total) resistance of two conductors having respectively four and five ohms resistance:

$$R = \frac{R_1 R_2}{R_1 + R_2} = \frac{4 \times 5}{4 + 5} = \frac{20}{9} = 2\cdot\dot{2} \text{ ohms.}$$

Example.—Find joint resistance of three conductors having respectively four, five, and six ohms resistance:

Putting values in formula,

$$R = \frac{4 \times 5 \times 6}{(4 \times 5) + (4 \times 6) + (5 \times 6)} = \frac{120}{74} = 1{\cdot}6 \text{ ohms.}$$

If the several resistances making up the circuit are similar, and each of the same resistance, then

$$\text{Total resistance} = \frac{\text{Resistance of one branch}}{\text{Number of branches}} = \frac{R_1}{n}.$$

Example.—What is total resistance of 10 conductors each having five ohms resistance?

$$R = \frac{5}{10} = \tfrac{1}{2} \text{ ohm.}$$

Digitized by Google

Example.—The joint resistance of two wires in parallel is two ohms. One wire has a resistance of five ohms: what is the resistance of the other?

$$R = \frac{R_1 R_2}{R_1 + R_2}, \text{ or, putting in known values, } 2 = \frac{5 R_2}{5 + R_2}$$

$$= 10 + 2 R_2 = 5 R_2 — i.e., 3 R_2 = 10, R_2 = \frac{10}{3} = 3\cdot\dot{3} \text{ ohms.}$$

I have said that the total resistance of the circuit is the sum of the internal and external resistances. This must never be forgotten. Usually it is the resistance of the external circuit that can be varied at will, and the internal resistance may generally be taken as constant.

We may take an example or two where French measures are used. Thus:

Example.—Two wires of same length and material have resistances four and nine ohms respectively. The diameter of one wire is 1mm. (millimetre), what is the diameter of the other?

$$\frac{R}{R_1} = \frac{d_1^2}{d^2};$$

putting known values,

$$\frac{4}{9} = \frac{d_1^2}{1^2}, \text{ or } \frac{4}{9} = d^2,$$

whence

$$d = \sqrt{\frac{4}{9}} = \frac{2}{3} = \cdot\dot{6}\text{mm.}$$

Example.—A mile of wire 2mm. in diameter has a resistance of 13 ohms: what is the resistance of 440 yards of wire of similar material 0·8mm. diameter?

$$\frac{R}{R_1} = \frac{L d_1^2}{L_1 d^2};$$

putting known values,

$$\frac{13}{R_1} = \frac{1{,}760 \times \cdot 8^2}{440 \times 2^2},$$

$$\frac{13}{R_1} = \cdot 8^2,$$

whence

$$R = \frac{13}{\cdot 64} = 20\cdot 3 \text{ ohms.}$$

Perhaps you will think I am giving you too much of these calculations, but, as I have before said, you must familiarise yourselves with them, and cannot work too many examples. It may be that the various tables give most of the results required in practice, and a glance shows the maximum current allowed for the various wires. Thus $^7/_{18}$'s S.W.G. have an area of ·0129 square inch, or, say, $\frac{13}{1000}$ of a square inch. If, then, one square inch, or $\frac{1000}{1000}$, carries 1,000 amperes, the $^7/_{18}$'s may carry 13 amperes. Similarly, $^7/_8$'s have an area of ·1435 square inch, and so may carry 143 amperes.

Once more let us look at the formula which symbolises Ohm's law—

$$C = \frac{E}{R}, \text{ or amperes} = \frac{\text{volts}}{\text{ohms}}.$$

We have seen how the total resistance of the circuit is made up, but we have not as yet considered its variability. The resistance of any circuit—simple or complex—is only constant when the temperature is constant. In some cases the raising of the temperature increases the resistance of the conductor; in a few cases the resistance diminishes with rise of temperature. At present I shall only touch upon the fact that ordinary copper conductors rise in resistance as the temperature rises. In England rise or fall of temperature is usually expressed in degrees Fahrenheit, though in scientific circles and abroad it is usually expressed in degrees Centigrade. The Fahrenheit scale marks freezing point at 32deg., and boiling point at 212deg., while the centigrade scale marks freezing point at 0deg., and boiling point at 100deg.—that is:

180deg. F. = 100deg. C.
9deg. F. = 5deg. C.
1deg. F. = $\frac{5}{9}$deg. C.
$\frac{9}{1}$deg. F. = 1deg. C.

It has been found by experiment that the resistance of pure copper increases by ·215 per cent. per degree Fahrenheit, or ·387 per cent. per degree Centigrade.

Messrs. Glover and Co. give the following table relating to resistance and temperature:

Metal.	Variation of R for Temp. Fahrenheit per deg. per cent.	Centigrade per deg. per cent.
Copper	·215	·387
Iron	·388	·700
German silver	·024	·044
Platinum-silver (2oz. silver, 1oz. platinum)	·017	·031
Manganin (manganese, nickel, copper)	·000025	·000045

Now, in actual work all conductors are heated by the passage of a current, and unless the current is too strong they are heated to such a temperature that the radiation of heat from the conductor is exactly equivalent to the heat generated by the current. If the current is too strong the temperature of the conductor continues to rise till it gets red, white hot, or fuses. You will at once understand that if a conductor is continuously radiating heat, and the heat thus radiated is renewed by the action of the current, there must be a continuous loss, a loss measured by the amount of heat radiated. I shall have to deal more fully by-and-by with this heating effect. Meanwhile we will restrict our attention to the increase in resistance.

An increase of resistance of ·215 per cent. means that a resistance of 100 ohms would increase to 100·215 ohms by a rise in temperature of 1deg. F. If the rise was 20 deg., then the resistance would be

$$100 + (20 \times \cdot 215);$$
$$= 100 + 4\cdot 3;$$
$$= 104\cdot 3.$$

You will see that this rise of temperature, a rise which is not infrequent, plays its part in working operations. The voltage that will drive a required current through a circuit of 100 ohms resistance will not drive that current through a circuit of 104 ohms resistance. Hence, if the current must be constant, a little higher voltage must be had when the circuit is raised in temperature than when at the lower temperature. I think I have now given you general notions sufficient to enable you to see the relations between current, resistance, and E.M.F.—that is, between amperes, ohms, and volts—that will be required for our immediate purpose.

MESSRS. SIEMENS BROS. AND CO.'S WORKS.

On Tuesday last a visit was paid by the Society of Engineers to Messrs. Siemens Bros. and Co.'s works at Charlton. Among those present were Mr. George A. Goodwin (president); Mr. H. Adams, Mr. C. Gandon, and Mr. J. W. Wilson, jun. (past-presidents); Mr. G. M. Lawford (member of council); Messrs. A. J. Bailey, W. Benbow, D. B. Butler, P. J. Dawson, B. P. Ellis, G. Garnett, E. E. Glaskin, P, Griffith, N. Harker, W. F. C. Hill, F. Hovenden, T. Huard, W. R. Manning, C. Mason, M. Mildred, J. A. Mingay, H. F. Packham, J. W. Ransome, W. F. Richmond, F. A. Robinson, S. Simmelkjor, E. H. Toulmin, A. Wollheim, R. G. Young, and G. A. Pryce Cuxson (secretary). All the machinery in the shops is driven by electric motors.

(1) *New Dynamo-Shop.*—The work carried on consists of the construction and erection of dynamos and alternators. The plant comprises two overhead travellers—(*a*) mechanical, lifts 10 tons, power transmitted by square shaft and gearing; (*b*) electrical, lifts five tons, one motor for each motion. Motors are 7 h.p., 6 h.p., and 5 h.p. respectively. Large facing lathe for central plates of alternators. Various lathes for turning and for boring out gap for armature in magnets. Drills, working up to a hole 4in. in diameter. Planing machines, the largest working over a surface 16ft. by 6½ft. (The steam-engine here is used only for testing dynamos, and does not drive the countershafting.)

(2) *Old Dynamo-Shop.*—General erecting work is carried on here. Small lathes, drills, and boring-machines. Punching-machines for iron cores of armatures, and copper end connections.

(3) *Milling-Shop.*—This contains milling-machines for small parts of machines which are required in large numbers. Capstan-headed lathes for screws, nuts, etc. Grinding-machines.

(4) *Gallery.*—Shaping and insulating parts of dynamo armatures and commutators.

(5) *Bobbin-Shop.* — Winding armatures and electromagnet bobbins.

Digitized by Google

(6) *Fitters' Shop.*—General fitting work. Lathes, drill, etc. Several driven by separate motors directly geared to them.

(7) *Carbon-Shop.*—The raw material is ground under edge-rollers, mixed, warmed, moulded into a round block, and then placed in the hydraulic press, whence it issues as a carbon rod. These are cut to length and then baked in ovens, first at a red heat, then at a white heat, after which they are slowly cooled down. Each furnace holds about 4,000ft. of 10mm. carbons.

(8) *Rubber-Shop.*—The raw rubber passes first through the washing-rolls, under a stream of water to rid it of mechanical admixtures such as sand, bark, sticks, etc. It is then dried for some time, after which it goes to the mixing-rolls, where various mineral substances are incorporated with it, according to the nature of the use which is to be made of it. The mixing-rolls are hollow, and steam or water can be allowed to circulate through them. The prepared rubber is then passed through the calendering-rolls, after which it is ready for the covering machines. Three layers are generally put on the stranded conductor—firstly, the brown pure rubber, then the white separator, and, finally, the pink jacket; the wire is then taped and taken to the vulcanisers, which are heated by steam. After vulcanising, the wire may be finished off in different ways—as braiding, covering with ozokerit, sheathing, etc.

(9) *Central Power and Lighting Station.*—The plant comprises three tubular boilers of gunboat type (two more in course of erection), each 18ft. long by 9ft. diameter, 400 i.h.p. each, 140lb. steam pressure (steam is largely used for heating purposes as well as for the engines). Four engines: one Belliss compound vertical enclosed, 300 i.h.p., running at 350 revolutions per minute; cylinders, 15in. and 23in. by 10in. stroke. Three Willans compound transfer condensing, I I I type, 300 i.h.p. each, running at 350 revolutions per minute; cylinders, 14in. and 20in. by 9in. stroke. Four dynamos, coupled direct to above engines, Siemens H.B. $^{21}/_{30}$ type for 120 volts, 2,000 amperes. Switchboard with regulating switches and measuring instruments. The distribution of the electrical energy is by means of underground lead-cased cables. Over the boilers are the condensers, consisting of 27 double-concentric cylinders; the steam passes through the annular space, while cooling water runs down inside and out. This water is used over and over again. There are in all 54 electric motors in the works: 13 of 40 h.p. each—four of these in the rubber-shop are directly connected by spur gear to the rolls; seven of 20 h.p. each; two of 15 h.p. each—these are directly coupled to a worm shaft driving the calendering-rolls in the rubber-shop, and are constructed to run at two different speeds; eight of 10 h.p. each—one of these is directly coupled to a cable machine, another works the lift in the rubber-shop; 24 of various powers, from 10 h.p. to ½ h.p., mostly directly coupled to lathes and other machine tools.

(10) *Switchboard Erecting-Room.*—All the regulating and starting switches and measuring instruments required for large central stations are put together here on massive slate slabs.

(11) *Cable-Shop.*—The deep-sea section of the third Atlantic cable for the Commercial Cable Company is in the course of manufacture. The served core passes into the rear of the machine through the hollow shaft which carries in an iron frame the bobbins for the sheathing wires. On rotating the frame carrying the bobbins, the cable being at the same time drawn along, the wires are laid spirally round the core. The bobbin carriers are actuated by cranks worked by an eccentric, so as to maintain always the same relative horizontal position, thus obviating any twist in the wires. After the sheathing wires, the cable receives finishing layers of jute yarn and compound. With "Jumbo," the largest cable machine, 64 sheathing wires can be put on in one operation. The rate of working is about five nautical miles of deep-sea cable per machine per 24 hours.

(12) *Tank-Houses.*—From the cable machines the cable is led directly into cylindrical iron tanks, where it is coiled away and kept under water. There are 10 tanks each for 150 to 200 knots of cable, and eight tanks each for 400 knots of cable.

(13) *Lead Cable-Shop.*—For the manufacture of lead-cased iron-sheathed cables for the underground distribution of large currents for electric light and power. The large stranding machine can lay up 37 wires at one operation. This strand is then covered with jute, dried, soaked in insulating material, and passed up through an hydraulic press. In this latter is a large ingot of cold lead, which under a pressure of 400 atmospheres is forced to flow out of the nozzle in a continuous pipe surrounding the wire. The final operation consists of serving it with jute and sheathing it with steel bands. These cables are intended to be buried directly in a trench dug in the ground.

(14) *Showroom.*—A museum of all kinds of electrical and telegraphic instruments and apparatus, both historical and novel.

Brazilian Submarine Telegraph Company.—The directors propose a balance dividend of 3s. per share, making a total distribution of 6 per cent. for the year ended June 30, and a bonus of 1s. per share. The sum of £15,000 is to be added to reserve, leaving £1,501 to be carried over.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Wootton-under-Edge.—Tenders are wanted for lighting the town.

London, W.C.—Mr. John Annan, manager for Mr. Samuel Wheeler, "Official Receiver in Companies' Liquidation," acting as liquidator of J. W. Hobbs and Co., Limited, is prepared to receive tenders for the supply and erection on foundations, etc., provided by contractor in the hotel in course of completion on the Salisbury Estate, Victoria-embankment, of the following plant: (Section A) boiler-house plant—boilers and fittings, feed heaters, electric feed pump, injector, water-tank, steam, exhaust, feed, blow-off, and sundry pipes and valves, etc.; (B) engine-house plant—oil-tank, steam dynamos, oil filter, workshop fittings, ventilating fan, etc.; (C) switchboard, instruments, and meters. Tenderers are at liberty to tender for any section or sections, or for the whole of the sections, but not for part of a section. The ground plan of the buildings, and the specification, with terms and conditions of tender and contract, may be obtained at the offices of Mr. R. Hammond, the consulting engineer, Ormond House, Great Trinity-lane, London, E.C., on payment of £2. 2s. Tenders to be addressed to Mr. J. Annan, 2, New-court, Carey-street, Lincoln's-inn, London, W.C., by 26th inst.

RESULTS OF TENDERS.

Lancaster.—The tender for the roof over the economiser at the central electric supply station, for the Town Council, by Mr. W. Richardson, has been accepted at £43.

BUSINESS NOTES.

Nottingham.—Many of the roundabouts at Goose Fair are lighted by electricity.

Western and Brazilian Telegraph Company.—For the past week the receipts were £3,186.

Appointment.—The City of Belfast want an assistant electrical engineer, at a salary of £120 a year.

Hull.—It is possible that the tramway system will be acquired by the Corporation and that electric traction will be introduced.

Bermondsey.—The electric light has been installed by Messrs. Tickner and Partington in the mills of Spratt's Patent, Limited, Bermondsey.

Colchester.—The Town Council have decided not to take at present any further steps for carrying out the provisions of the provisional order.

La Boite Magique, Limited.—This Company has been registered with a capital of £3,000 in £1 shares to carry on business as mechanical engineers, electricians, etc.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending 7th inst. amounted to £908, as compared with £666 in the corresponding week of last year.

Worthing.—The Town Council have adopted without discussion the minutes of the Electric Lighting Committee, which recommended the employment of a consulting electrical engineer to furnish plans and information.

Church-Lighting.—A large congregation attended on Sunday evening at Castle-gate Congregational Church, Nottingham, when the electric light was used for the first time. The work has been carried out by Messrs. Thomas Danks and Co., of Thurland-street, Nottingham.

Bangor (Wales).—The Town Council want an extension of the borrowing powers for gasworks. In a discussion on this subject Dr. Grey Edwards, one of the Council, objected to unnecessary expenditure on the works, seeing that there was a possibility of the electric light superseding gas.

Poplar, E.—The Board of Guardians have referred to a committee a letter from the Poplar Board of Works asking the Guardians whether, in the event of the Board installing electric light in the district, they would be prepared to take the same for their premises for a stated period.

City and South London Railway.—The receipts of the Company for the week ended October 7 were £892, against £816 for the corresponding week of 1893, or an increase of £76. The total receipts for the current period of the present half-year amount to £12,011, as against £11,296 in the corresponding period of 1893, an increase of £716.

Submarine Cables Trust.—This Trust notifies that on and after October 15 the sum of £1. 15s. on account of the coupon due the same date will be paid by Messrs. Glyn, Mills, and Co., of 67, Lombard-street, between the hours of 10 a.m. and 2 p.m. The coupons should be left with the bankers for examination four clear days before payment.

Fareham.—The sanction of the Board of Trade with reference to the purchasing of the Fareham Electric Lighting Company by the Local Board has been received. The central body state that they will "consent to the transfer of the undertaking on being assured that the electric lines referred to in the 82nd section of the order have been placed underground."

T. and R. Boote, Limited.—This Company has been registered, with a capital of £50,000, to acquire as a going concern the business of earthenware and tile manufacturers, stone and flint grinders,

Digitized by Google

and manufacturers of electrical apparatus and appliances, now carried on at the Waterloo Potteries and Patent Tileworks, situated at Burslem, Staffordshire, under the style of T. and R. Boote.

Colchester.—The Lighting Committee of the Town Council have reported that only 14 replies had been received to the circulars sent to the inhabitants of the district it was proposed to light by electricity, the total number of lamps required being 152. The committee therefore recommended the Council not to take any further steps at present. The recommendation was adopted.

Change of Address.—Mr. A. H. Bayes, late of 34, Newnham-terrace, Westminster Bridge-road, has removed to 23, Western-street, Midland-road, Bedford. Messrs. Gilbert and Co. have now removed from Hanway-street to their new and more extensive works at 142A, Oxford-street, W., where they have increased facilities for manufacturing their specialities. Their office address will be at Kensington, as before.

Carlisle.—The Carlisle Gas Committee have considered the notice of application for a provisional order to supply Carlisle with the electric light, sent to them some time ago by the Brush Company, of London. They came to the conclusion that the best course to pursue would be to recommend the Council to apply to Parliament themselves for a provisional order to enable them to supply electric light to the citizens, and they accordingly passed a resolution to that effect.

Elmore Copper Tubes.—We are informed that Elmore copper tubes have been adopted by her Majesty's Government, and by the leading railway companies as a direct result of tests made in every instance. A number of steamships have also been fitted throughout with Elmore steam-pipes. It is stated that the prices at which Elmore tubes of 4in. diameter and upwards are now offered will render unnecessary the further use of brazed copper tubes, even on the plea of cheapness.

Bury.—At a meeting of the Electric Lighting Committee on September 4 there were present the Mayor (chairman), Councillors Butcher, Collinge, and Thornley. The borough engineer reported upon the tenders for the electric lighting plant and machinery, and the County Council this week resolved that an opportunity be given the whole of the persons originally tendering to submit fresh tenders for the continuous-current plant already adopted, and that the time for tendering be extended to October 15.

Wells.—The Lighting Committee of the Town Council have reported that it was desirable in the interests of the citizens to adopt the electric light for the city, but that it should be carried out by the Urban Sanitary Authority, and that the town clerk should ascertain from other towns where similar works have been carried out the name of a competent engineer to advise the Authority, and report the same at the next meeting. After a long discussion the recommendations of the committee were adopted.

Cheltenham.—The Mayoress (Mrs. Wethered) has laid the memorial-stone at the new electric lighting station, at the ash-destructor, near the Midland Railway. The system of lighting adopted is that of the high-pressure alternating, and the current will be supplied to customers at the price of 6d. per Board of Trade unit, with rebates to large consumers. The undertaking is in the hands of the Corporation, who will for the present confine their attention to supplying private customers. The question of street lighting by electricity remains over for further consideration.

Edinburgh.—It has been remitted by the Town Council to the Cleaning and Lighting Committee to consider and report on the subject of lighting by electricity the following streets—viz., George-street, St. Andrew-square, South St David-street, South St. Andrew-street, South Hanover-street, South Frederick-street, South Castle-street, South Charlotte-street, Hope-street, and Charlotte-square. It was reported that the deputation to London to inspect the electric arc lamps had cost £29. 16s., equally divided between the two members, Bailie Dunlop and Mr. Mackenzie.

City of London Electric Lighting Company, Limited.—The return for the quarter ended September 30 states that the revenue from the sale of current for public lighting amounted to £3,142, as compared with £3,027 for the corresponding period of last year; that from the sale of current for private lighting £7,677, against £3,552, and the estimated revenue from other sources was £416, against £441; the gross amount being £11,235, an increase of £4,214. The equivalent of 8-c.p. lamps connected on September 30 shows an increase during the quarter of 13,724, the increase during the corresponding quarter last year being 7,526.

Wimbledon.—The Road and Drainage Committee of the Local Board have recommended that the Board take the necessary steps to carry out the surveyor's recommendation for a dust destructor. Mr. Casswell, in moving the adoption of the recommendation, said the amount of refuse to be disposed of was so large, and the sewage farm was being so overdone with sludge, that a destructor was becoming absolutely necessary. Mr. Olley seconded. Mr. Crickmay, in proposing that the matter be allowed to stand over for three months, said he was as much opposed to the scheme now as he had ever been. Mr. Donaldson seconded, and the amendment was carried.

Cartmel.—A correspondent has written to an Ulverston paper in regard to the want of railway communication. He says that the vale of Cartmel is not approached from either end save by the old mode of locomotion. He suggests that a meeting of the inhabitants of the several parishes in Cartmel should be convened to discuss the question whether it is not possible to prevail upon one of the railway companies to take the matter up, or in the alternative to form an independent company with a limited capital for the construction of an electric railway from Cark or Kents Bank, through the vale of Cartmel to Newby Bridge and Bowness, with a possible extension in the future to Coniston and other parts of the Lake District.

Portsmouth.—The electric light in Portsmouth is an almost unqualified success, says the *Hampshire Telegraph*. The street-lighting is brilliant, and in spite of its greater cost than gas the inhabitants in some districts not served by it are pleading for an extension of the system. As for the house and shop lighting, it has given general satisfaction. All who use the incandescent electric light are loud in its praises. They speak of the purer atmosphere, the better light, and the greater comfort in working. With regard to the cost, they say the extra sums they have to pay are more than outweighed by the advantages, especially in those businesses where the use of gas has a deteriorating effect upon the goods exposed to it.

Motherwell.—The Motherwell Police Commissioners have received a report from Mr. Mavor, electrical engineer, Glasgow, regarding the introduction of electric lighting into the burgh, in which he stated that electric lighting might be introduced with good prospects of success. The cost of erecting a station in Motherwell he estimated at £12,500, including the cost of obtaining the provisional order and making suitable provision for possible extension. The Board, having regard to the fact that a private company intended to apply shortly for a provisional order to light the town, agreed unanimously to adopt the report, and take the necessary steps to carry out the scheme, which, it is believed, will not increase the rating of the burgh.

Liverpool.—Mr. Meade-King, at a meeting of the Town Council, drew attention to the lighting of St. George's Hall and the Municipal Offices, and said he thought the time had arrived when the incandescent electric light, which had been so generally adopted, should be used in those buildings. Alderman Rathbone said the question had been before the sub-committee over and over again, and was still before it, and he thought they could go into the question next year. A great many experiments had been tried with regard to electric lighting, some of which had not been successful, and it was simply a question as to when was the best time to make the change. No doubt such a change would have to be made; it was only a question of time.

Hampstead.—The Vestry have decided to insure the electric supply station and plant against fire for £15,000 on a general policy, the boilers for £2,000, and the economiser for £300. Mr. Preece is to report whether, in the event of the mains for the private lighting being extended, it is advisable to lay at the same time an extra main for the public lighting. A memorial has been received from a number of shopkeepers in Fairfax-road, asking that the electric light might be supplied to their places of business. A letter has been received from Messrs. R. Dellagana and Co., of 10, Gayton-road, photo-zinc etchers, referring to the necessity of an early extension of the electric lighting plant required in their business, unless the Vestry were prepared to supply them.

Acton.—Mr. William Terriss, of Bedford-park, has written to the Local Board asking if there was any probability of the electric light being installed in Acton, as he and many other residents in Bedford-park would be glad to use the light. The Works Committee reported that they had instructed the clerk to reply to Mr. Terriss's letter, but no information was vouchsafed by the committee as to the nature of the clerk's reply. The Chairman said it would be well to keep Mr. Terriss's letter. The Board had now several applications for the electric light. At a later stage of the meeting the chairman observed that several firms were now making tentative offers for the purchase of the Board's electric lighting order. The Board decided to give the competing firms a month in which to prepare their tenders.

Birmingham Tramways.—An extraordinary general meeting of the Birmingham Central Tramways Company, Limited, was held on Wednesday, when the following resolution was passed: "That the capital of the company be reduced from £500,000 (divided into 10,000 fully paid-up 5 per cent. guaranteed shares of £10 each, and 40,000 ordinary shares of £10 each, of which 38,000 are fully paid up, and 1,200 have not been issued or agreed to be issued) to £300,000, divided into 10,000 fully paid-up 5 per cent. guaranteed shares of £10 each. and 38,800 fully paid-up ordinary shares of £5 each, and 1,200 unissued ordinary shares of £5 each; and that such reduction be effected by cancelling capital which has been lost or is unrepresented by available assets to the extent of £5 per share upon each of the said 38,800 ordinary shares which have been issued and are now outstanding, and by reducing the nominal amount of such 38,800 ordinary shares and of the said 1,200 unissued ordinary shares from £10 to £5 per share."

Brighton.—At a meeting of the Lighting Committee of the Town Council it was resolved to place a brass tablet on the electric lamp-pillar at the bottom of Regency-square, at an estimated cost of £3. 10s, bearing an inscription commemorating the inauguration ceremony of lighting the front by electricity performed by the Mayoress (Miss Ewart) on September 16, 1893. The confirmation of the proceedings having been moved, Alderman Hawkes expressed the opinion that the names of the Mayor and Mayoress and the members of the committee should be placed on the tablet. The Mayor said there would be no room on the tablet for the names. Besides, only one name need be put upon it, that of the Mayoress. Alderman Reeves thought it would be only doing what was customary to put the names on the tablet. Alderman Lowther pointed out the difficulty of putting a lot of names on the tablet, and Councillor Berry, in reply, said he thought it was quite sufficient to record that the Mayoress switched on the light.

Digitized by Google

The amendment on being put was lost, and the proceedings were passed.

Whitehaven.—Mr. Jonathan Cant, who is seeking re-election on the Town Council, in the course of an address to the ratepayers has stated that he was an opponent of the attempt of the gas company to monopolise the lighting of the town, and a supporter of the adoption of electric light, which was likely to be a very great success. From figures submitted at the trustee meeting it appeared that for the first year there had been a profit of £143. The present supply of electricity was fully taken up, and they required to have two more sets of engines and dynamos. A further statement of the probable result after those had been erected, showed that the profit would then be £232 Besides that, at the end of the 20 years for which they had borrowed their money for the works, the whole of the present debt on electric lighting account would be repaid, and the present plant would belong to the town, and be absolutely free, so that they would then probably be able to have electricity very much cheaper than they had at the present time, or, if not, their profit must necessarily be much greater than it was now.

Stafford.—The Electric Lighting Committee recommended to the Town Council the acceptance of Messrs. Siemens Bros. and Co.'s tender for £1,290 for supplying conductors on the three-wire system. They also recommended that the electric department of the Corporation should keep a staff of their own for wiring just as the gas department did for pipe-laying. It was also thought best to excavate the trenches for the conductors by the Corporation's servants. The tender of Messrs. W. G. Bagnall and Co., Limited, for £75 for overflow main and exhaust pipe for engines was recommended for acceptance. Alderman W. H. Peach moved the adoption of the report. The tenders for conductors had been referred to Dr. Hopkinson, and he recommended the acceptance of Messrs. Siemens Bros.', and should have done so if it had not been the lowest. He had had experience of Messrs. Siemens's work at Whitehaven, and they had always given perfect satisfaction. Dr. Hopkinson strongly recommended the acceptance of the tender. The various works at the electric lighting station were progressing satisfactorily. Mr. G. J. Flamank seconded the adoption of the report, which was carried.

Luton.—The Highways and Lighting Committee reported to the Town Council last week that the town clerk had brought up the resolution passed by the Town Council at their meeting on the 18th ult. requesting the committee to bring up a report upon the probable cost of obtaining a provisional order for the supply of electricity for public and private purposes in the borough and as to the desirability or otherwise of applying to the Board of Trade for such order. After consideration of the question it was resolved and ordered that the town clerk prepare a series of queries upon the subject-matter and forward the same to boroughs where electricity is used. At an adjourned meeting on October 1, the town clerk reported that in compliance with instructions he had prepared and forwarded to 51 town clerks a series of questions as to electric lighting, that he had received 44 replies, and that he had such queries and answers and caused the same to be printed. It was resolved that in consequence of the voluminous nature of the document so prepared, and owing to the impossibility of duly considering the same, a special meeting of the committee be held on Friday, the 12th inst., to consider the whole question, and prepare and submit a report thereon to the Town Council at their meeting on the 16th inst.

Bournemouth.—The Electric Lighting Committee of the Town Council reported last week that they had received a letter from the secretary of the electric supply company offering reduced terms for the electric lighting of the Winter Garden, and also a letter from Messrs. Roger Dawson, Limited. The committee recommended that the town clerk reply that the Council are not prepared to accept the terms proposed, but would be willing to enter into an agreement for 5½ years, as from September 29, on being allowed a discount of 40 per cent. on the current price for the time being, instead of 15 per cent. as at present. A letter had been received from the Local Government Board asking for a copy of the approval of the Board of Trade to the system proposed to be adopted, and as to the advisability of providing an additional small engine The committee recommended (1) that the surveyor prepare a statement of the system proposed, and that the town clerk apply for the sanction of the Board of Trade to the same; (2) that the town clerk, on the receipt of such approval, forward a copy of it to the Local Government Board; and (3) that the town clerk reply to the other portion of the above letter that the Council had considered the point raised by the Board, and did not think it advisable or necessary to provide another engine. These reports were adopted.

Bradford.—On Tuesday, at a meeting of the Town Council, the minutes of the Sanitary Committee, the adoption of which was moved by Mr. L. Walker, the chairman, and seconded by Mr. M. O'Flynn, stated that at a meeting held on September 18 the committee inspected the electric light installation recently provided at the Hammerton-street destructor works. Mr. Hezekiah Lister asked when the "mountain" at the Southfield-lane destructor was to be removed. Had an arrangement been made with respect to the removal of the nuisance caused by this great heap of refuse? If not, he hoped that steps would speedily be taken to remove it. Mr. J. S. Toothill said he would be glad to know something more about the electric lighting installation at the Hammerton-street destructor. Mr. Walker, in reply to Mr. Lister, said that they had already begun to lead the "clinkers" away from the Southfield-lane destructor, and no more "clinkers" would be put on the hill. With respect to the electric light at the Hammerton-street destructor, the installation was not costing more than £100. The work, it was expected, would be completed this week. The gas bill for the destructor was £57 per annum, and the committee hoped that in a year or two they would be able to pay the whole of the expense of the electric plant out of the saving effected by using the electric light instead of gas. The minutes were adopted.

Folkestone.—When the Town Council met last week, Councillor Thompson drew attention to the electric wire being placed over the public highway Sandgate-road and West Cliff Gardens. He said it was absolutely necessary that they should know their position in reference to the matter. If a private individual could do what was being done now, it must prejudice in future the Corporation in introducing electric light, and still more would it prejudice their powers to part with their provisional order, should they ever obtain one, to a private company. It was not only the fact of overhead wires, but they had also had their pavements taken up for the purpose of laying down electric wires, and he thought they would all agree that they ought to take some action in order to ascertain what powers they did possess, and what their real position in the matter was, and what the Board of Trade would do under the circumstances. None of them would object to the parish church being supplied with electric light in itself, but it was necessary for them to ascertain what their real position was. He moved that the town clerk be directed to report to the Board of Trade the fact that a private individual was supplying electric light by means of overhead wires, and that the Board of Trade be requested to take the necessary steps under the Electric Lighting Act of 1888. Councillor Pursey seconded the motion, which was adopted.

Newport (Mon.).—Mr. F. Phillips at a meeting of the Corporation, referring to a clause of the Works Committee which left the question of the number of electric lights and the kind of fittings for the Town Hall and other public buildings to a sub-committee, spoke of the need of putting practical men, such as Alderman Huzzey, on the sub-committee. He did not think men who had not had that experience were able to deal with the matter, and moved that the matter should be reconsidered. Mr. Wilkinson (filling up the pause): Well, sir, for the sake of discussion, I will second it. Alderman Moses said the duties of the sub-committee involved merely a question of taste in fittings. He, of course, yielded to others more endowed on matters of taste, but he did not think practical men were necessary in such a matter. Besides, to increase the sub-committee would increase the expense. Mr. F. Phillips: I do not object to Alderman Moses. Mr. Greenland: I suppose my friend objects to me. As far as I understand, it is a matter of taste of certain brass and iron pendants; but I do not feel that the question of taste is insurmountable as far as I am concerned. Mr. T. Jones thought the mover of the amendment altogether misconstrued the duties of the committee. It was merely to go to the manufacturers and select goods. Mr. Goldsworthy supported the report, and Mr. Parnall pointed out that the sub-committee would have the aid of the electrical engineer, who was thoroughly abreast of the latest types of goods. Afterwards the report was adopted.

Hereford.—The Gasworks Committee reported to the Town Council last week that they had received notice of the intention of the Great Western Electric Light and Power Company to apply for a provisional order to supply electricity within the district. They therefore recommended that it was desirable the Corporation should obtain a provisional order, and that the Council take steps as they might deem necessary to obtain the order. The Mayor moved that the report be adopted. With regard to the provisional order for electric lighting, the committee had thought it prudent to make application for such an order in self-defence. He might say that the credit of making the proposal might certainly be given to the town clerk, who called attention to the matter, and the committee then very properly adopted his recommendation. Mr. Williams seconded. The Deputy-Mayor said he should like to know a little more about the provisional order they were to embark upon. It was an Act of Parliament in a small way that they were going in for. He should like to know the position of things, what time they must move, what was to be done, and what expense they were to be put to in obtaining a provisional order; and, when obtained, whether the Council would be obliged to go on with the work, or whether the powers would lapse if they did not do so? This was a matter which ought to receive some consideration. He thought it had better be referred to a committee, so that the subject might be considered in all its bearings. After further discussion the subject was referred to the Finance Committee for consideration.

Larne.—A number of complaints with regard to the unsatisfactory state of the lighting of the town was made by several of the members at a meeting of the Town Commissioners. Mr. Foster complained of the state of the lighting arrangements in the town at present. In the neighbourhood of the Roddens—a portion of the town where there were many gentlemen's residences—the lamps were very frequently out, and one evening recently not only that portion of the town, but Mount-pleasant and Fair-hill, were in darkness. Mr. Picken also complained of the badly-lighted state of the Curran. Mr. M'Cay stated that the residents of the Bank-road had just cause to complain of the unsatisfactory state of the light in that district. Mr. Fullerton entered into an elaborate explanation in defence of the electric company, which, he said, was doing its best to meet the wishes of all concerned, and had, he thought, given every satisfaction of late. With regard to complaints of lamps going out, he thought people should exercise a little forbearance, as accidents rendered it necessary that the light should be out occasionally. He added that Bailie Crawford, of Glasgow, who was recently on a visit to Larne,

Digitized by Google

expressed the opinion to him that it was the best-lit country town he had ever been in. Mr. Foster took exception to the fact that 100-c.p. lamps had been erected at the open, where the Board were paying for 1,200 c.p., and he understood that for this 100 c.p. it was proposed to charge them £9, while the price in the schedule for a 500-c.p. lamp was £7. 10s. This discussion, which lasted almost an hour, was finally ruled by the chairman out of order.

Southport.—In moving the minutes of the Gas and Electricity Committee at Tuesday's meeting of the Town Council, Alderman Robson referred to the resolution passed by the committee—"that the price of gas for all purposes other than lighting be reduced 6d. per thousand cubic feet, provided the gas is supplied through a separate meter"—and expressed the opinion that it would be unwise to adopt such a plan. If they granted these advantages to those who consumed gas, they would have to do the same in respect to the electric light consumers. Moreover, he contended that all ratepayers who consumed gas should be treated alike. With respect to the recommendation of the committee that the tender of the Fowler-Waring Cables Company, Limited, to supply 1,200 yards of high-tension cable for Scarisbrick New-road at £57 per mile be accepted, he said that it meant an entire change in the system of electrical distribution—a change which had been strongly condemned by their electrical engineer. Councillor Hesford said this step was taken under the exigencies of circumstances, and on the advice of their electrician. The work of constructing their electricity supply works was so far advanced that by November 9 they would be able to turn the electric current into the mains. It was proposed on that occasion to illuminate the Town Hall and the Cambridge Hall, and the trees and gardens in front, with incandescent lamps. Alderman Fisher said the main object of the committee in passing the resolution with regard to the reduction of the price of gas was to keep the works constantly going in summer as well as in winter. After an unusually lengthy discussion, the minutes were passed.

Canterbury.—The Electric Lighting Committee of the Town Council reported as follows: A letter from Messrs. Mowll and Mowll, of August 20, as to the price of the electric light and the power of same was read, and it was resolved that the Brush Company be asked to send down their engineer to inspect the city streets and to consult with the committee as to the position and number of electric lamps which it is desirable to have erected. A sub-committee, consisting of Alderman Mount, Councillors Warren and Mourilyan, were requested to meet the engineer. Councillor Dean said he saw the sub-committee was to meet the engineer to the Brush Company, and he asked had the Council decided that they were going to give the company the lighting? The Mayor said no. The engineer was only coming down for purposes of information. The Town Clerk, explaining, said the sub-committee were going round with the engineer practically in order that the company might "make out their case" as to the desirability of the electric lighting. An appointment was made, but shortly before the time fixed the engineer telegraphed to say he could not come at the arranged time. The Surveyor stated that he had had a letter from Messrs. Mowll and Mowll to the effect that the engineer would come down next week and would let them know the day. Alderman Cross said it would be very desirable that the inspection should take place after dark. Alderman Mason said he really hardly knew what the engineer was going to do. The surveyor already had a plan showing the places where it was thought desirable these standards should be placed, and what the Council really wanted to know was how many ordinary gas lamps these electric lighting lamps would replace, and the difference of the cost, in order that the Council might then consider whether it would be worth while to enter into a contract for the public lighting or not. The matter then dropped, and the report was confirmed.

The Electric Tramway to Kingstown and Dalkey.—The work of constructing the electric tramway between Haddington-road, Blackrock, Kingstown, and Dalkey will shortly be entered on by the Dublin Southern Tramways Company, who own the undertaking. The line is virtually owned by the Imperial Tramways Company, Limited, and at their recent meeting in Bristol some interesting facts in connection with the coming electric project were disclosed. The company's system will be reconstructed as double lines in connection with working the traffic by electric traction in place of animal power. The Thomson-Houston system is the one which the company submitted to the authorities when they were obtaining their Act, and the British company sent their engineer and traffic experts to Dublin to gauge the position for themselves, and from what they saw they formed a high opinion of the earning capacity of the line when worked by electricity. The present outlay on the laying of the double line, rearranging their Ball's Bridge depôt as a power station, and equipping the line with electric power and motor cars is estimated at about £70,000. Towards this outlay it is proposed that the Imperial Company shall raise by debentures £10,000 in cash, the remainder being mainly subscribed by the Thomson-Houston Company, while the permanent-way contractor, who shares their views as to the future success of the lines, will take up the necessary balance. The company's present gross receipts in Dublin are about £11,000 a year earned with a 15-minute service, which with horses is necessarily slow, but when the electric installation is made there will be a five minutes' service, and with an electric tramway worked at quick speed, the directors calculate that they will be able to cope with the very large traffic which is to be obtained in the district throughout the summer, as well as the influx of traffic on the numerous occasions of exhibitions, shows, and public entertainments at the Royal Dublin Society's grounds, which are direct on the line. The Thomson-Houston Company's experts are satisfied that the traffic will be so very materially increased, while the percentage of expenditure will be reduced on the present and increased traffic to 55 per cent., that there will be ample profit to pay the preferential charges on the new capital and leave a substantial dividend on the ordinary capital, all of which is owned by the Imperial Company. Dublin will shortly be placed in the position of a pioneer of electric traction for public streets and thoroughfares in Ireland, though in this matter Portrush has on a small scale the advantage.

Burton.—The Gas and Electric Lighting Committee reported to the Town Council that the mean illuminating power of the gas in standard candles had been 18·40. There was need for extending the area of the supply of the electric light, and the committee recommended that Mr. Ramsden, manager, should issue circulars to the residents of Ashby-road to ascertain how many would be willing to have the light if conveyed thither. The committee further asked for power to take the best professional advice as to the safest means to prevent further contamination of water in the neighbourhood of the gasworks. Alderman Lowe proposed the adoption of the report, and stated that at present the electric light was not a paying concern. If, therefore, they could extend its use by the laying of fresh cables, the committee thought it would be advisable to do so; hence, the recommendation to apply to the residents on Ashby-road. Councillor Graham, in seconding the motion, referred to the contamination of the water near the gasworks, and suggested that the Council should erect pumps which would over-balance those used by the brewers, and so prevent water which had passed by the gasworks being brought back again, as was the case at present. Alderman Evershed, while admitting that the brewers had been the innocent cause of scarcity of water among ordinary householders, warned the Council to think seriously over the matter before they embarked on a huge system of pumps as suggested. Councillor Morris remarked that the committee were almost unanimously in favour of something being done in the direction indicated by Councillor Graham. Alderman Lowe replied that the committee would not enter into a scheme of pumping which would entail a large or unnecessary expense, but they thought they ought to have advice as to the best way to put an end to the claims made against them for the contamination of the water supply. The proposition was then carried.

Cardiff.—During the consideration of the minutes of the Lighting and Electrical Committee at Monday's meeting of the Cardiff County Council, the Mayor (Mr. W J. Trounce) said he should like to know whether the information contained in the Press was accurate or not. There was no doubt that the electric lighting should have been completed months ago, and there was no reason for deferring it to this late period. Many of their shopkeepers had been waiting for it, but the application forms had not yet been distributed. He thought it was full time that the light should be instituted, as they were now losing large sums of money in the way of interest. Mr. C. Waring: How many applications have been made to have the electric light put in on private premises at Cardiff? Alderman Jacobs: About three. Mr. Waring: Don't you think that the Lighting Committee should institute a canvass of some sort? Many tradesmen would like to have it, but they don't know anything about it. The Mayor said there was great apathy on the part of the private consumers. Mr. Waring remarked that to make the electric lighting pay it would be necessary to have from 4,000 to 5,000 consumers. Up to the present they had only about 40, he understood. The Mayor said he was told that the application forms were not printed a few days ago. Mr. Waring proposed that a representative of the Corporation be appointed to canvass amongst the tradespeople of Cardiff. Mr. Good asked on what authority Alderman Thomas Rees had recently stated that the electric lighting would not be ready for six months. The Mayor: I understand it will be ready in the course of a week. Alderman Thomas Rees: My remark was only a play upon words—a figure of speech. Mr. Vaughan, chairman of the Lighting Committee, said there was no one more disappointed than he and the members of the committee at the delay—he thought it had been unnecessary. First, there was the question of the strike, and the contract could not be carried out in time. Then, after the engines and dynamos had been put up they found that certain pipes of various dimensions were to be got, and it was contended by the engineers that these things could not have been fixed until the condenser, boiler, and engines had been erected. With regard to the canvassing, he did not think any members of the committee would consent to act as canvassers. They had issued pamphlets giving all particulars, yet they had only three applicants for the light. The people were, therefore, not waiting for them, but the Corporation were waiting for the people. No doubt, when they got their public buildings lighted, there would be an increase in the number of applicants. Alderman Richard Cory suggested that if they could not find a clerk of their own to canvass the town, they might employ someone on commission. The discussion then dropped.

Woking.—The question of the electric light and its reliability has during the past few days considerably exercised the minds of most of the tradesmen of the Woking Station district, to whose houses and places of business it is laid on. On one or two occasions there have been trifling interruptions in the supply of electricity, but a rather more serious difficulty occurred lately, when for a considerable time the light was not available, owing, it is believed, to a slight disarrangement of an engine at the works. The failure of the supply occurred soon after six, when most of the business places had commenced to light up, and it was quite half-past seven before the current was turned on again. Naturally,

Digitized by Google

considerable inconvenience was caused to many of the shopkeepers, though some who, like Messrs. Wenham, have gas in front of their business premises were not so much affected. The defect at the works was, of course, remedied with the utmost possible despatch, and the current again turned on. A number of the tradesmen of the district felt that the question of the reliability of the light was an important one, and it was decided to hold a meeting of those interested to see what could be done to secure an uninterrupted supply during the winter months. The meeting was held at the assembly-room of the Liberal Club, when Mr. R. Gloster presided, and amongst those also present were Messrs. S. C. Knight, Wenham, Geddes, Ivens, A. G. Clinton, Finch, T. Gloster, Lovett, Gunning, Saul, Underhill, and De Neuville. The Chairman commented on the irregularities in the supply, and pointed out that consumers had gone to the expense of purchasing fittings, and it would be a matter of some expense if they had to change their mode of lighting. Mr. Knight said unless the supply was more satisfactory he should certainly consider the advisability of lighting his premises by other means. Mr. Mayne, who was present, gave an explanation of the circumstances by which the interruption to the light was caused, and mentioned that the supplying of the street lamps would not interfere with the supply to private consumers. The company were purchasing a new engine, and even before that arrived he felt sure they would be able to satisfy all the demands made upon them. He thought he could safely promise them a good supply in the future. It was then decided that those present should consider the question of calling another meeting if thought desirable. It will be seen by the statement made by Mr. Mayne that the company are doing their utmost to secure a perfect service, and it is to be hoped that in this they will be successful. The work of erecting the standards to carry the lamps for lighting the streets is being pushed forward, and it is expected that in a short time the installation will be complete, and the streets of Woking, at any rate of the Station district, properly lighted—a reform which will be most welcome to everyone living in the neighbourhood.

PROVISIONAL PATENTS, 1894.

October 1.

18542. **Improvements in facsimile telegraphs.** Harry William Charles Cox and Richard Joseph Crowley, 51, Cricketfield-road, London.

18559. **An improvement in electric conductors.** Albert Walter Gamage, 126, Holborn, London.

October 2.

18661. **An improved frame or holder for detachable electric fuses.** The Acme and Immisch Electric Works, Limited, and Ernest Francis Moy, 433, Strand, London.

18662. **An improvement in switches for electric circuits.** The Acme and Immisch Electric Works, Limited, and Ernest Francis Moy, 433, Strand, London.

18673. **Improvements in electric mechanism for winding and synchronising clocks.** Henri Fréderic Mouquin, 53, Chancery-lane, London. (Complete specification.)

October 3.

18696. **Improvements in instantaneous, quick-break, double-pole switches.** Frank Henry Starling, the Gresham Electrical Works, Nottingham.

18743. **An improvement in collectors for overhead electric conductors.** Arthur Henry Bagnold, 28, Southampton-buildings, Chancery-lane, London.

18753. **Improvements relating to the transmission of telegraphic signals and to apparatus therefor.** John Mabry McMahan, 11, Southampton-buildings, Chancery-lane, London.

18754. **Improvements relating to the transmission of telegraphic signals and to apparatus therefor.** John Mabry McMahan, 11, Southampton-buildings, Chancery-lane, London.

18755. **Improvements in and relating to apparatus for intermittently closing and interrupting electric circuits.** John Mabry McMahan, 11, Southampton-buildings, Chancery-lane, London.

18757. **An improved insulation for either high or low tension cables and joints in same particularly.** William Parrott, Albert Essinger, and Thomas Harden, 26, Thavies-inn, Holborn, London.

18767. **Improvements in automatic switches for transformers or other electrical appliances.** Darwin Bates, Thomas Harden, and Oliver Leopold Peard, 70, Chancery-lane, London.

October 4.

18809. **Improvements in or connected with secondary or electric storage batteries.** Frank King, 47, Lincoln's-inn-fields, London.

18814. **Improvements in electric batteries.** Basile Alexandrovich Balasny, 6, Bream's-buildings, Chancery-lane, London.

18854. **New or improved instrument for use in ascertaining the description of leads or conductors required to suit conditions of electrical systems.** Charles William Godson Little, 47, Lincoln's-inn-fields, London.

October 5.

18860. **Improvements in the automatic connection of conductors conveying alternating currents of electricity.** George Kirby Chambers, 10, Richmond-villas, Seven Sisters-road, London.

18910. **Improvements in and relating to vessels for electrolytical purposes.** Peter Jensen, 77, Chancery-lane, London. (Hans Cappelen and Diderik Capelin, Norway.) (Complete specification.)

18925. **Improved means of attaching electric lampholders to oil lamps.** Frederick Charles Bryan Robinson, 55, Chancery-lane, London.

18933. **Improvements in apparatus for making and breaking electric circuits.** Haydn Thies Harrison, 46, Lincoln's-inn-fields, London.

October 6.

18996. **Improvements in or relating to brush and commutator mechanism for dynamos.** Alexander Ramsay, 6, Lord-street, Liverpool.

18999. **Improvements in electric fuses for mines and like purposes.** William Phillips Thompson, 6, Lord-street, Liverpool. (La Société M. Gaupillat and Co., France.)

SPECIFICATIONS PUBLISHED.

1893.

17172. **Covers for junction-boxes for electrical distribution, etc.** Baynes.

19809. **Carbons for electrodes, etc.** Castner.

23309. **Continuous-current dynamos.** Hutin and Leblanc.

1894.

7145. **Electro-deposition of zinc, etc.** Cowper-Coles and Walker.

10044. **Luminous electric changeable writing.** Theodoli.

13794. **Electric conduits.** Eisenhuth and others.

14607. **Electric cable traction apparatus.** Lamb.

14642. **Electrical battery.** Feeny. (Dubero and another.)

15276. **Diaphragms for electrolytic purposes.** Kiliani and others.

15321. **Telephone cords.** Schrimpff and Riffelmacher.

NOTES.

Electric Lighting in Brazil.—There is some talk of lighting Alagoas with electricity.

Neuhausen Aluminium Works.—The output of these works is now three tons per day.

New London Exhibition.—Next year an exhibition, entitled "The Light and Heat Exhibition," is to be held at Woodhouse Park, W.

Danish Telephony.—Negotiations are in progress between the Danish and German Governments to establish telephonic communication between Copenhagen and Berlin *vid* Odense, Kolding, and Hamburg.

Electrolytic Processes in South Africa.—The Meyer and Charlton Company is about to follow the May Consolidated Company's example in adopting the Siemens-Halske electrolytic process of treating tailings.

The Indian Telegraph Department.—The ultimate sanctioned superior strength of the Telegraph Department is 86 men. There are now only 74, but three new assistants are to arrive from Cooper's Hill this month.

The House of Commons.—Electrical communication is to be established between the Chamber, the library, and the smoking-room, and the division bells will be extended to the Grand Committee-room in Westminster Hall.

Electric Lighting in Burmah.—There is a proposition, which may be carried out, to light the new Government House and other public institutions in Rangoon with the electric light, the dynamo and machinery being worked in the gaol.

The Kinetoscope.—The apparatus used in connection with the kinetoscope, which reproduces living action without sound, and of which a demonstration was given at 70, Oxford-street, W., on Wednesday evening, is driven by an electric motor.

Electric Launches.—The Spree-Havel Steamship Company intend, in connection with the Berlin Exhibition of 1896, to run twenty-two electric launches on the river. The accumulators to be used will be those of the Allgemeine Elektricitäts-Gesellschaft.

"Science Progress."—We have received the October number of this magazine, which is published by the Scientific Press, Limited, 428, Strand. It contains the first of a series of articles on continuous-current dynamos by Mr. C. C. Hawkins, M.A.

A Revival.—Although *La Lumière Electrique*, as mentioned a few weeks ago, has become defunct, a new journal bearing the title of *L'Eclairage Electrique* has made its appearance. This journal, published at the same address as *L'Electricien*, seems to be a resuscitation of *La Lumière Electrique*.

British Association Screw Threads.—A card concerning the British Association screw threads has been forwarded to us by Messrs. Davis and Timmins, Limited, of 28, Hatton-garden, E.C. The card, which gives the dimensions in millimetres and thousandths of an inch, will prove very handy.

Electric Lighting in Hungary.—Mr. Franz Pelikán, the electrical engineer to the Prague Municipality, has drawn up five different schemes for the electric lighting of the town, which will receive due consideration. The Wenzelplatz in the same town has been lighted electrically by means of 42 Krizik arc lamps.

Fire at Telegraph Works.—We regret to learn, from paragraphs published in yesterday's daily papers, that part of the premises of Henley's Telegraph Works, in Store-road, North Woolwich, was destroyed by fire on Wednesday evening. The cause of the fire is attributed to the boiling over of insulating compound.

Limelight versus Electric Light.—The electric light is to be substituted within two months for the limelight at the South London Music Hall. This is to be done to please the Theatres and Music Halls Committee of the London County Council, otherwise the renewal of the license would not have been recommended.

Transmission of Power in Italy.—A portion of the water power of the Lake of Amman, about three miles distant from Pordenone, is now being profitably utilised for the electrical transmission of power to a cotton mill at Pordenone. The electrical plant has been supplied by Messrs. Brown, Boveri, and Co., of Baden, Switzerland.

Electric Transmission in Spain.—A project has been drawn up by Major Julio Cervera for utilising the falls of the River Gabriel, in the province of Cuenca, for the electric transmission of power. Over 10,000 h.p. is available, and work has been commenced. It is proposed to transmit the current to Madrid, Valencia, and other places.

New German Company.—There has been formed in Germany the Gesellschaft für Elektrische Unternehmungen (Company for Electrical Undertakings), with a capital of £750,000. The concern has been founded by the Diskonto Gesellschaft, Dresdner Bank, Bank für Handel und Industrie, Ludw. Löwe and Co., S. Bleichröder, and Born and Busse.

Testing of Meters.—The London County Council announces that it is now in a position to test electric light meters. The tests will be made by competent electricians, and the amount of the fee for testing each meter will depend "upon its capacity and mode of construction." Communications on the subject are to be addressed to the Engineer-in-charge, London County Council Testing Station, 42, Cranbourne-street, W.C.

Telephony in Germany.—The postal authorities are going to establish telephonic communication between Striegau, Schweidnitz, and Breslau. The line between Gotha and Friederichroda will be carried out next spring. Work is to be commenced at once in establishing telephonic communication between Frankenthal and the network of the Palatinate. Telephonic communication has been established between Berlin and Wolgast.

New Catalogue.—We have received from Mr. William Rickard, Ashbourne-road Mills, Derby, a wholesale catalogue and price-list of his manufactures, including British standard wire-gauge wire, plain silk and cotton-covered wires, guttapercha-covered line wires, paraffined line wires, twin line wires, flexible bell cords, fancy handle cords, telephone terminal cords with metal tags, braided double flexible cords, electric light leads, and electric light cables.

Athletics.—The City Electric Lighting Athletic and Football Club, who have just started their first football season, played the return match between the two departments, Worcester Wharf and Wool Quay, on Saturday last on the Hackney Marsh ground. The first match resulted in a win for the Worcester men by ten goals to three. A much closer and better game ensued on Saturday, but in the end the Worcester men again proved victorious, scoring three goals to their opponents' one.

At it Again.—Good old *Kuhlow's German Trade Review!* We have received the issue of October 10, which in all contains five items relating to the electrical industry of Germany. Four of these are lifted from our issue of 28th ult. and one from our issue of 14th ult., and all without

Digitized by Google

any recognition of the source. Even if our contemporary does not care to acknowledge where its information is obtained from, the least it could do would be to scissor the matter a little more promptly.

The Indo-Chinese Telegraph Line.—The connection between the India and Chinese telegraph systems will be made from Nampoung to Momein, the distance between these two places being between 60 and 70 miles only. The alignment will thus be along the valley of the Taeping River, which is the caravan route for trade between Burmah and Yunan. The posts and wire for the whole of the new line will be sent from India to Bhamo and thence onward to Nampoung, where work will be begun by the Indian telegraph officers.

"Life of Edison."—Messrs. Chatto will, on the 25th inst., publish "The Life and Inventions of Thomas Alva Edison," a large-paged, finely-illustrated volume. The authors are Antonia Dickson and W. K. L. Dickson, who, as they explain in a short preface, have been intimately associated with Edison during the past 13 years. As a result of this, they have had every assistance put at their disposal for the preparation of his "Life." Indeed, there can be little doubt that some parts of the work will be more or less autobiography. Among the 200 pictures there are several portraits of Edison and his family, and one of his residence, Glenmont, New Jersey.

Breaking-up of Streets.—It appears from a report presented to the Vestry of St. Martin-in-the-Fields that the superficial area of pavements disturbed in that district during the year 1893-94 by electric supply companies was considerable. For instance, the London Electric Supply Corporation opened up 311⅓ superficial yards of York footway, and 60 yards of asphalte foot and carriage way, granite carriageway and wood paving. The Metropolitan Electric Supply Company disturbed 75⅓ superficial yards of York footway and 25 yards of other forms of pavement. The Electricity Supply Corporation opened 416 superficial yards of York footway and 66 yards of other pavement.

Electrical Accessories.—In a new price-list just issued to the trade, Messrs. O. Berend and Co. illustrate a variety of electrical accessories. Commencing with different kinds of branch switches, the list passes on to main switches for both high and low pressures. Next come the "V. H." multiple-contact accumulator switches, which by the insertion of a suitable spiral wire resistance prevent injury to the cells arising from short-circuiting. Another type of switch for regulating purposes is on the Burger system. Cut-outs for low and heavy currents then receive attention, together with safety fuses, wall sockets, resistance frames, arc lamp resistances, lightning protectors, etc.

Exhibition at Amsterdam.—An international exhibition comprehensively illustrating hotel arrangements and accommodation for travellers generally, as well as means of transport by sea and land, has been decided upon by the city of Amsterdam, and will be opened there in the summer of next year. The buildings are to be erected on the land situated at the back of the State Museum on the site occupied by the universal exhibition of 1883, and they will cover an area of 160,000 square metres. The necessary funds both for carrying out and guaranteeing the undertaking have already been provided, the plans of the various exhibition buildings are being prepared, and their construction will be shortly taken in hand.

"Daylight" Incandescent Lamps.—A price-list of the "Daylight" incandescent lamps, placed on the market by Messrs. O. Berend and Co., of 61, Fore-street, E.C., has reached us from this company. The filament of this type of lamp comprises a chemically pure carbon wire which is exceptionally elastic and harder than glass. The lamps are exhausted to a specially high vacuum. This fact, combined with the properties possessed by the filament, ensures the lamps a long life, a well-maintained candle-power, and less blackening of the globes. The lamps recommended are the economic "Daylight" lamps, having an efficiency of from 2 to 2½ watts per candle-power. A speciality is made of lamps for theatrical, surgical, and other purposes.

Electric Traction in Germany.—Yet another scheme has been put before the Berlin Municipality for an electric tramway by a Mr. H. Grauel. It is partially of the switchback order. In Hamburg the authorities have before them a scheme for a high-level electric railway prepared by Mr. Eustace Langen, of Cologne. Mr. Osthoff, of Berlin, has laid before the Municipality of Flensburg an electric tramway project, but the authorities have decided to do nothing in the matter until they have had some experience of the working of the local central electric light station. The managers of the Frankfort-Eschersheim local railway propose to substitute the electric trolley system for steam on their line early next year. Messrs. Schuckert and Co. are going to build an electric tramway from Wiesbaden to Sonnenberg—a considerable distance—and a company has been formed, with a capital of £10,000, to carry out the undertaking.

French Cable Companies.—The Exchange Telegraph Company's Paris correspondent, referring to the question of the fusion of the two French cable companies, states that it is by no means certain that the scheme can be carried out as projected by the financiers, who are anxious to get rid of a heavy parcel of shares and bonds of the Société Française des Telegraphes Sous-Marins, which the public has hitherto refused to take up. They had hoped to obtain a subsidy from the French Government, but independent shareholders of the P. Q. Company have strongly protested against the confiscation of their assets for the sole benefit of the clique. When the matter was mooted in Council the other day, it was decided to refer it to a special telegraph committee, and it is to be hoped that this committee will look carefully into the question before giving a favourable opinion, which, in fact, they could not do if they dealt with it impartially.

"The Engineering Magazine."—With its October issue this magazine inaugurates a departure towards which it has moved since it was started. It has already for some time published a technical index to current literature, but this idea has now been developed, and one portion of the magazine will henceforth be devoted to giving "expert reviews of the most important publications of the month, in every field of applied science; to supply a complete index to all the leading articles published in the scientific and industrial journals of all the English-speaking peoples; and, finally, through the Clipping Bureau, to furnish the original and full text of each and every publication so reviewed or catalogued. That is to say, as a review it does for industrial literature precisely what the *Review of Reviews* does so admirably for the political and literary world; as an index it is to the technical expert just what Poole's index to periodical literature has long been to the literary worker."

Paris Central Electrical Laboratory.—Since referring several weeks ago to the Laboratoire Central d'Electricité, which is located at 12 and 14, Rue de Stael, Paris, we have received a circular concerning the object and regulations of the laboratory. As we then dealt fully with the matter, it will only be necessary to

Digitized by Google

mention a few of the charges made for testing and standardising instruments. For the tests in the first category, entitling commercial instruments to a certificate, the following charges are made: direct-current ammeters of from 0 to 100 amperes, 5f.; from 100 to 500 amperes, 10f.; and from 500 to 100 amperes, 20f. Direct-current voltmeters reading from 0 to 150 volts, 5f.; from 150 to 500 volts, 10f.; and from 500 to 100 volts, 20f. Alternating-current ammeters and voltmeters of from 100 to 1,000 amperes, or of 150 to 1,000 volts, 20f. Standardising a meter, 40f. The circular then gives the charges for testing cables, insulators, lamps, resistances, batteries, and dynamos.

Metallic Electrolysis.—Perhaps one of the most valuable papers, from a therapeutical and practical value, read recently before the American Therapeutical Association, was the one by Dr. Wm. J. Morton, of New York, on "Metallic Electrolysis," "Cataphoresis," etc., with illustrated cases—such as trachoma, tinitus-aurium, vascular tumours, cysts, etc. The paper in its first part, according to the New York *Electrical Review*, dealt with a historical review of some of the subject-matter. In fact, the groundwork was gone through so thoroughly that nothing was left wanting either scientifically or otherwise. His physiological experiment on cat muscular fibre are highly to be praised for its originality, and has thus gone far to prove the fact that metallic electrolysis is most valuable. He examined cat's muscle under the microscope while electric diffusion was being performed. By the aid of the microscope he watched the diffusion of the copper. In removing these deposited minute particles and testing them, they were found to give the reaction for copper.

Patent Agent Logislation.—The Select Committee on the Patent Agents Bill report that they have not been successful in their efforts to induce the general body of patent agents to agree upon the terms of a Bill that would be acceptable to them all. They have, therefore, been left to deal with the matters before them without such assistance. The most important feature in their report is its emphatic assertion of the inexpediency of allowing the exclusive right of communicating with the Patent Office to fall into the hands of any body of men, "or to create a monopoly in respect thereof." While considering it desirable that there should be a roll of duly-qualified patent agents, they express the opinion that there should be no regulation to prevent solicitors or other professional men from transacting business at the Patent Office, or to compel an inventor to employ any particular class of agent. The committee admit that it would be of public advantage to give to patent agents an improved professional standing and organisation; but, on the other hand, they declare that they "do not consider that the Chartered Institute of Patent Agents, as at present constituted, sufficiently represents the general body of the practitioners at the Patent Office."

The Proposed German Atlantic Cable.—There is naturally a good deal of excitement and anxiety among the proprietors in the Anglo-American Telegraph Company, says the *Morning*, in consequence of the scheme for a German Atlantic cable, with a Government guarantee of about £70,000 per annum. But as that project will have as its basis the exclusive right to land at the Azores and other points, a difficulty is quite likely to arise from the side of the United States Government, who may make it a condition of the new cable being landed on their territory that American citizens shall also have the right to land cables at the Azores and in Portugal. It will be interesting to watch how this difficulty will work out, for we have reason to believe that it is a real stumbling block in the way of the carrying out of the project. The concession has been taken up by the Eastern Telegraph Company, and as the same gentlemen figure on the boards of that and of the companies whose business is threatened by the competitive scheme, it is to be presumed that when they have got everything in shape they will have the grace not to seek to retain their seats on the whole of them, including the Trust companies, which have an enormous stake in the existing cable companies, and whose affairs they also administer.

Electro-Harmonic Society.—The next smoking concert will be held on Friday, the 26th inst., at the St. James's Hall Restaurant (Banquet-room), Regent-street, W., at eight o'clock. The musical directors are Mr. T. E. Gatehouse and Mr. Alfred E. Izard. The following is the programme—Part I.: madrigal, "What, Ho!" (Beale), the London Glee Singers; song, "False or True" (Allitsen), Mr. Robert Fisher; pianoforte solo, "La Campanella" (F. Liszt), Mr. Alfred E. Izard; song, "Hush, Dear Heart" (Behrend), Mr. Charles Chilley; recitation, "The Building of St. Sophia" (Baring Gould), Mr. J. K. Boddy; violin solo, "Romance in F" (Beethoven), Mr. T. E. Gatehouse; song, "The Tempest" (Ed. St. Quentin), Mr. R. E. Miles; burlesque lecture, "The Decease of C. Robin, Esq." (Leigh), Mr. C. E. Nott. Part II.: violin and piano, Andantino and Allegro, from "Sonata in B Flat" (Mozart), Mr. T. E. Gatehouse and Mr. Alfred Izard; song, "Edward Gray" (Sullivan), Mr. Alfred Pinnington; song, "Fairer Than Morning" (A. Cecil), Mr. R. E. Miles; recitation, "The Three Parsons" (Overton), Mr. J. K. Boddy; violin solo, Andante and Rondo, from the "Seventh Concerto"), (De Bériot), Mr. T. E. Gatehouse; old song, "Tom Bowling" (Dibdin), Mr. Charles Chilley; humorous song, "The Learned Leviathan" (Paulton), Mr. C. E. Nott.

Liverpool Engineering Society.—The opening meeting of the twenty-first session of this society will be held on the evening of Wednesday, the 24th inst., at eight o'clock, when the president-elect, Prof H. S. Hele-Shaw, Wh.Sc., M.I.C.E., will deliver his inaugural address. For the succeeding meetings the following is the proposed scheme of papers to be delivered—viz., November 7—Mr. W. Rowland, Wh.Sc., "Recent Improvements in Locomotive Design"; November 21—discussion on ditto; December 5—Mr. S. Dunkerley, M.Sc., "The Whirling and Vibration of Shafts"; December 19—Prof. Oliver J. Lodge, D.Sc., LL.D., F.R.S., "The Second Law of Thermo-Dynamics"; January 9—Mr. John A. Brodie, Wh.Sc., A.M.I.C.E., "Tramway Traction"; January 23—Mr. W. Worby Beaumont, M.I.C.E., "The Theory and Action of some Automatically-Balanced Machinery"; February 6—Mr. H. H. West, M.I.C.E., "The Stability of Ships"; February 20—discussion on ditto; March 6—Mr. D. B. Morison, M.I.M.E, "Experiments in Connection with Evaporation"; March 20—Mr. F. G. Baily, M.A., and Dr. C. A. Kohn, Ph.D., B.Sc., "A Scheme for the Distribution of Energy in Towns"; April 3—Mr. J. Reney Smith, Wh.Sc., "Engineering Work and Operations at Perim Island"; April 24—Mr. Arthur Musker, "Artificial Paving Slabs"; and May 1—annual general meeting—discussion upon miscellaneous communications.

Horse Racing by Electric Light.—The racecourse at Maspeth, Long Island, belonging to the Newtown Jockey Club, has been lighted by electricity, and is the second American course where the electric light has been introduced, the first being that at East St. Louis. The novelty is reported to have proved a complete success.

Digitized by Google

The jockeys say that there is plenty of light, and that they feel perfectly comfortable in running the race. There has been no accident, no interference, and no swerving of any account, and, what is more, both the public and the club are pleased with the arrangement, which has been carried out by Messrs. Curtis and Dean, of New York. The Maspeth racecourse is half a mile long, and closed in by a high fence of white board. The track is lighted at night by clusters of incandescent lamps suspended over the middle of the course, the light being thrown down by reflectors. The horses as they run round are followed by powerful search-lights. Arc and incandescent lamps light up the grounds and grand stand. The electric plant includes two boilers, two 115-h.p. engines, and two Edison 100-kilowatt generators. There are 200 clusters of four 32-c.p. lamps each over the track, 100 32-c.p. lamps distributed about the entrances, betting ring, offices, etc., 50 16-c.p. lamps, 28 arc lamps, and three 6,000-c.p. search-lights. During the race the load is 1,050 amperes at 135 volts. The track is wired in three sections, and these sections in turn are wired so that, if one machine were to break down, alternate clusters of lamps would burn, so that the chances of the course being thrown into total darkness are very remote. Tests taken one morning after 12 hours of soaking rain showed a variation between the most distant lamps and those nearest to the station of less than three volts.

Electric Ballet.—On Monday there was provided at the Oxford Music Hall a sort of ballet which was described as "The Carnaval Electrique." This is understood to have been a great success at Blackpool, from which place it has been transferred to London. It is evident that when Lancashire trippers go to enjoy themselves they are not very exacting in the matter of entertainment, for the ballet in question is not striking from the point of originality in any way. The programme gives the names of the designer and maker of the dresses, the manufacturer of the wigs, the composer of the music, the arranger of the ballet, and the producer, but though stress is laid on the fact of the electrical features, no information is vouchsafed as to who has carried out the electrical arrangements, though it is mentioned that the "electric effects" have been "originated by Mr. William Holland." The ballet for the longest part of its course has nothing suggestive of electricity about it, but just at the end the stage is darkened, the ballet enter with festoons in front of them and conductors behind them, the festoons containing white, red, and green incandescent lamps, and similar festoons are also suspended underneath the sky-border. First of all, the white circuit is switched on and turned off; then the red is dealt with similarly; and finally the green, winding up with all three together. It will be seen that this is merely a development of the display given on the roof of Pears's soap warehouse, close in the neighbourhood, every evening. A young lady also gives a sort of serpentine dance, the underside of her dress being sprinkled over with white incandescent lamps, plum-pudding fashion. Her movements are, however, hampered by the fact that she is anchored by her cable. A special "pome' has been written in praise of the electric light.

The City and Guilds of London Institute.—The report on the work of the examination department of the City and Guilds of London Institute for the session 1893-94 states that during the session the number of classes registered was 853—701 in technology and 152 in manual training. The total number of students in attendance was 25,718. In the previous session the number of registered classes was 734, and the attendance of students was 24,374. At the examinations held in 1894 the total number of candidates examined was 11,631, or 1,377 in excess of the number examined in the previous year. The examinations in technology were held in 344 centres in the United Kingdom, and also in New South Wales, New Zealand, and Bombay. The number of home candidates was 9,814 out of a total of 9,907. The number of London candidates was 1,360, so that the number from centres outside the metropolitan area was 8,547, which, compared with 7,520 in the previous years, shows that the withdrawal of grants on results has had no appreciable effect in retarding the normal increase in the number of candidates. The percentage of failures has fallen from 46·4 to 44·6, but this result is in no way due to any lowering of the standard. A noticeable feature of the work of the session is the institution of preparatory classes in electric lighting and typography, an arrangement which has been attended with very satisfactory results and a demand for its extension. The classes in manual training are intended exclusively for teachers in public elementary schools, and the number of teacher-students in attendance was 3,015. At examinations held at the close of the session, 1,816 candidates presented themselves, of whom 1,256 satisfied the examiners. The training given in these classes is intended to qualify certificated teachers to give instruction in wood and metal work. In the new programme, the syllabuses of instruction and the lists of works of reference have been carefully revised, and, in response to applications, arrangements have been made for an examination in bookbinding.

The Havre Electric Tramways.—A few weeks ago we referred to the official opening to traffic of the electric tramways in Havre. A noteworthy feature in this connection is that all the lines in the town have been simultaneously converted from horse haulage to electric propulsion, a fact which has never previously been exemplified in any European country. The Compagnie Générale Française des Tramways some time ago entrusted the Thomson-Houston Company to supply the rolling-stock, and asked the Société l'Energie Electrique, of Havre, the local electric lighting company, to furnish current for the working of the tramways. The tramway system in Havre comprises three main lines. The first, which starts from the jetty and ends at Graville, is about 3½ miles of double line; the second beginning at the Rond-point, Rue de Normandie, terminates at Sainte-Adresse, the length being three miles; and the third connects the main quays and the basins. A fourth line, now in course of construction, will be carried along the Boulevard Maritime. At present the total length of single line worked is 14·88 miles. The rails are of the Humbert type, weighing 27 kilogrammes per metre, and laid on metallic sleepers. The gradients reach 4 per cent., and the smallest curves have a radius of 18 metres. The overhead conductor is a hard copper wire 8·25mm. in diameter, suspended in the usual manner in the centre of the track at a height of 6·50 metres from the ground—that is to say, partly from the cross-arms of steel standards, and partly from the fronts of houses. The steel standards have been brought into requisition for the lighting of the main thoroughfares, and for this purpose arc lamps to the number of 85 have been fitted in carriers on the top of the standards. The tramway service is dealt with by 40 cars, each having accommodation for 50 passengers. The electrical equipment of the cars depends upon the lines upon which they are operated For instance, 24 cars are fitted with only one motor, and 16 with two motors, of a normal power of 25 h.p. The supply of current for the working of the cars is obtained from the central station of the Société l'Energie Electrique

Digitized by Google

in the centre of the town. Here four alternators, rope driven, have for some time furnished current for private purposes. Now three four-pole Thomson-Houston dynamos, giving current at 500 volts at a speed of 425 revolutions, have been installed for dealing with the tramway system. The substitution of electric for horse traction has already brought about an increased traffic, and at the same time the tramway company have reduced the fares.

Two-Wire Distribution at 200 Volts.—In the now defunct *Lumière Electrique*, M. G. Claude discussed a few months ago the difficulty of obtaining in a three-wire system of distribution a sufficient regularity of voltage, and mentioned the interest there would be in suppressing purely and simply the intermediate wire. M. Claude now takes up the subject once more in the columns of *L'Eclairage Electrique*, with special reference to a letter received by him from M. P. Vitte, the electrical engineer to the Compagnie du Gaz de Lyon, who furnish both a supply of gas and electric light. To quote from the letter in question, M. Vitte says: "Why not dispense with the middle wire so as to distribute directly at 200 volts, and feed the lamps arranged in groups of two in series. I add that those lamps that cannot be conveniently grouped in twos and must remain isolated, whether the subscriber desires only one lamp, or the particular application necessitates one lamp and not two working simultaneously, whether for any other cause we could employ 200-volt lamps a little more fragile than the others, but certainly realisable at the present for intensities of 16 and even 10 candles. Many lamps of five candles at 110 volts are made. It is only necessary to place two of the corresponding filaments in series, with a few precautions, to have 10 candles at 220 volts. In one word, the necessity of having in some cases recourse to isolated 200-volt lamps more fragile and a trifle more costly, cannot constitute an argument against distribution at 220 volts by means of two conductors, given the great advantages of this method of distribution and the possibility of reducing to a very small fraction the number of these isolated lamps. A station constructed for 200 volts and two conductors would certainly have fewer troubles than is generally supposed." With regard to this quotation, M. Claude states that nothing better can be said. In his article already referred to, he did not insist upon the possibility of directly branching lamps on 200 volts, because, as mentioned by M. Vitte, if 200-volt lamps are realisable, they are not so practical at the moment as 100-volt lamps. But as he, M. Claude, had only in view, in devoting himself to distribution at 200 volts on a two-wire system, the possibility of obtaining in a practical manner the forcing of the lamps to 2·5 watts per candle, he thereby eliminated even those systems of lamps which would not be able to bear such an action, and he had wrongly extended this elimination to all cases. M. Vitte, however, reminded him rightly that the case of 200-volt lamps would only be the exception, but that their existence would always give the possibility of offering satisfaction to a subscriber who, against his own interests, would like to have recourse to the system of isolated lamps. M. Claude considers that this is another argument in favour of the method of distribution indicated, and he tenders his thanks to M. Vitte for having afforded him the opportunity. M. Claude, however, regrets one thing—that the distributing system of the Lyons station comprises two wires only, otherwise the experimental verification of these views on part of a circuit of a three-wire distributing system would have no doubt long since been an accomplished fact.

The Submarine Detector.—It is now a little over a year since the Russian monitor "Rusalka" foundered with all hands in a storm in the Gulf of Finland. Steps have since been taken by the Russian Government to discover the precise locality of the ill-fated vessel, with the view of raising her, an expedition having been organised for that purpose. This expedition consisted of a flotilla of several vessels equipped with divers and all necessary apparatus, including one of Captain M'Evoy's submarine detectors, which was made in London for the expedition. It has recently been ascertained that the spot where the "Rusalka" went down is a reef in the locality of the Wäster Tokan. The reef is submerged, and it is supposed that the "Rusalka" grounded there, and subsequently slipped off into the surrounding deep water. Her precise position has been localised in 30 fathoms of water by means of the submarine detector, a description of which, says the *Times*, may prove interesting. This apparatus is based on the principle of Prof. Hughes's induction balance, and it consists simply of an electrical arrangement contained in a small mahogany box, which is carried on board the searching vessel, and a sinker, which is trailed along the bottom. The sinker also contains an electrical arrangement, and is connected with that in the box by a light electrical cable of any required length. The apparatus includes a small battery and an automatic contact breaker, which opens and closes the battery circuit at short intervals. The battery circuit includes two primary coils, one in the box and the other in the sinker. Each primary coil has its secondary coil, and both the primaries and secondaries are respectively connected up by conductors, which are enclosed in the suspending cable. In the searching vessel there is a telephone, which is included in the secondary circuit. Before being used the apparatus is adjusted so that under ordinary circumstances little or no sound is heard in the telephone, notwithstanding the pulsations of the primary current. The reason of this is that the induction in one secondary coil is, by adjustment, made to neutralise the induction in the other secondary coil. When, however, the sinker approaches a mass of steel, iron, or any other metal the adjustment is deranged, and sounds become audible in the telephone, while they are reduced in intensity as the sinker recedes from the metallic object. Three hundred feet of electrical cable were employed with the detector in searching for the "Rusalka," and the depths searched varied from 15 to 50 fathoms. The search was continued for several weeks, and the exact position of the foundered vessel was at length placed beyond all question, as every time the searching steamer passed over a given spot the electric indicator of the detector sounded loudly, thus affording evidence that a large mass of metal was submerged below. After the vessel had been located the divers descended and examined her. Although most appropriate for the purpose of searching for wrecks of iron ships, the submarine detector was not primarily designed by Captain M'Evoy with that sole view. His main object was to provide a means of indicating the approach of iron ships to anchored torpedoes, as well as of searching for stray torpedoes, lost anchors and chains, telegraph cables, and the like. In the first-named case, the induction produced near the torpedo is neutralised by another induction on shore, the torpedo and the shore station being connected by a cable. The approach of a mass of metal, such as an enemy's ironclad, to the torpedo disturbs the balance, and causes the sounds to become audible in the telephone. The torpedo may then be fired electrically by means of the cable connection, the invention thus presenting itself as an important adjunct of coast defence.

MECHANICAL TRACTION FOR TRAMWAYS.

(Continued from page 327.)

Electric tramcars are provided with either one or two motors, according to the grades to be encountered and general character of the traffic. When it is advisable that the whole weight of car should be employed for better adhesion either at starting or ascending a grade, the usual method is to have two motors, one on each axle, rather than couple the axles together. This arrangement is of course more expensive, and it increases the dead-weight and general cost, but at the same time offers more security and ease, or power of regulation, by employing one or both motors, in accordance with the requirements, at any instant. On the Marseilles tramway, equipped three years ago, two motors are fitted to each car; the magnetic fields of both are coupled in series, whilst the armatures are in parallel. Regulation is effected by means of a variable resistance in the circuit; whilst high speeds are given on the level by shunting the field magnets, so as to weaken the fields.

In the Thomson-Houston system the two motors are coupled in series when starting, and may be connected in parallel for ordinary speeds, or one of them cut out of circuit when the resistance to be overcome is small. Five different connections are thus obtainable:

1. Two motors in series, with a variable resistance in circuit. (Position at starting.)
2. One motor cut out.
3. Both motors in circuit, the field of one being shunted.
4. Both motors in parallel.
5. Fields of both motors shunted.

These are found sufficient to serve for all practical purposes, but on long grades both motors are sometimes short-circuited on one another with a resistance inserted. This arrangement constitutes an electric brake of great power and steady action. By reversing the armature or field-magnet current, the car may be stopped on the steepest grade and started again up hill.

A system based on that of Sprague is used in France by the Fives-Lille Company, the regulation being effected with great independence of working in the two motors. The field-magnet winding includes three separate coils which may be joined in series or in parallel, or two in parallel with the third in series, or cut out of circuit altogether, thereby giving a great variety of possible field arrangements. The two armatures are coupled in parallel except at starting: and a rheostat or variable resistance is only employed at starting or on long descending grades when the motors act as generators of current.

The motors are arranged on the cars in such a way as to be protected as much as possible from dust and mud: usually each armature is enclosed in a cast-iron frame or box forming a portion of the magnetic circuit and protecting the working parts, thereby considerably reducing the working expenses and cost of repairs. The Thomson-Houston "waterproof" motor is cited as an instance of this: the magnets are double polar with either two coils or a single one. Carbon brushes set 90deg. apart are used, in order to run either way. The Sprague motors made by the Fives-Lille Company are designed without a break in the magnetic circuit: the interior working parts are rendered accessible from the side instead of by removing a top cover. The considerable speed of electric motors renders necessary some intermediate device for connecting their spindles with the car axles. Sprocket wheels and chains were at first employed to some considerable extent, but do not seem to have given unalloyed satisfaction: and toothed gears now obtain the preference. At first, high-speed motors, each with a double set of gear, became general; but owing to their great absorption of power and heavy trouble due to wearing out and constant renewals, single pairs of gear wheels are now used, the motor speed being reduced accordingly. This entails a greater weight in the motors and a lower working efficiency, but still ensures better results taking everything into account. The motor speed with single-reduction gear seldom runs above 500 to 550 revolutions a minute for an output of 15 h.p. to 20 h.p.

The motor frame in this arrangement is fastened at one end to the underframe of the car by means of springs, whilst the other end is carried by the driven axle. The gear wheels rotate in a bath of oil contained in the iron casing.

Since even a single pair of toothed wheels may give trouble through breakage, motors are sometimes designed of such slow speed as to be coupled directly to the car axles. In these "gearless motors," as they are called, the armature is usually not mounted on the car axle itself, but upon a hollow spindle, through which the car axle passes, and which is attached to the wheels by means of very powerful springs. The field-magnet system is carried from bearings on the hollow spindle. In this method, the losses due to gearing, etc., are avoided altogether, but, on the other hand, the motor efficiency is extremely small at the slow speeds necessitated by coupling them direct to the car axles; the motor weight is also much increased. It seems therefore a matter of some difficulty to attempt a decision with regard to one method being more efficient or advisable on the whole than another.

In dealing with the question of efficiency in general on electrically-worked tramways the author appears hardly to be abreast of the times, for although the somewhat unfavourable results at which he arrives are such as were to be found in the early days of electric working, we are able now by the help of storage battery stations and better speed regulation to secure a more even working load and a higher average efficiency.

M. de Marchena, in entering upon figures, states that the fuel consumption seldom falls below 3½lb. per electrical horse-power at the generator terminals, even under the most favourable conditions, while it is usually much above this rate. Loss on the line he takes to be about 10 per cent. with practically perfect insulation. These estimates would, however, appear to be far too high when results on the Liverpool, South Staffordshire, and other lines are examined. Motors, of course, cannot possibly attain a high efficiency, owing to the conditions under which they work. As a rule, their design is based rather on qualities of strength, lightness, ease of repair, and everyday working rather than high theoretical efficiency. At full load their output is taken at from 70 to 75 per cent. of the input, as compared with a 90 per cent. efficiency of dynamos under favourable circumstances. Here, again, the figures would seem to be by no means excessive, but, of course, more modern instances would show greater improvement.

Trials made at Milan upon a short length of line gave a final result of 50 per cent. efficiency between the electrical horse-power at the central station and the mechanical horse-power at the car axle, not inclusive, therefore, of the generating plant; only 10 cars, however, were in use, and either great loss of current must have taken place along the line, or the motors were of an inefficient type, or else the average traffic requirements were quite abnormal.

Results are also given of tests made by the Fives-Lille Company on some eight-kilowatt motors operating cars of a weight equal to seven or eight tons on the line, with an average capacity for 30 passengers. With two such motors, on a car seating 28 persons, the results were as follows:

Motor field connections.	Speed kilom. per hour.	Current in amps.	Grade per cent.	H.P.	Efficiency per cent.
			Up. Down.		
Three in series	12·2	8	·75	2·7	50
	9·7	16	·61	6	55
	7·5	24	2·15	8	49
Two in parallel, third in series with them ...	12·6	10	·5	3·7	54
	10·7	20	1·26	8·6	63
	8·6	30	3·6	12·6	62
Three in parallel	18·3	10	·75	4	61·5
	13·5	20	1·03	10	74
	12·2	30	2·96	15·9	78
	11·5	40	4·85	20·2	76
	9·1	60	8·48	27·9	68
	8·8	70	10·5	31	65

In these trials, the speed reduction was as 1 to 5; working pressure, 500 volts.

Similar tests were made with cars of the same size and weight, but each fitted with a single motor. The following table gives the results obtained in this way also:

Digitized by Google

Field motor connections.	Grade per cent.	Speed kilom. per hour.	Current in amps.	H.P.	Efficiency per cent.
	Up. Down.				
Three in series	1·07	12·2	4	1·35	50
	·29	9·7	8	3	55
	·58	7·5	12	4	49
Two in parallel, third in series with them ...	·93	12 6	5	1·85	54
	·07	10·7	10	4·3	63
	1·25	8·6	15	6·3	62
Three in parallel	1·075	18·3	5	2	61·5
	·06	13·5	10	5	74
	1·05	12·2	15	8	78
	2·13	11·5	20	10·1	76
	4·2	9·1	30	14	68
	5·37	8·8	35	15·5	65

The average efficiency according to these results works out to about 60 to 65 per cent., without counting the losses due to starting or slowing down in actual work. Reckoning the losses on line, in the motors, and the generating plant at the fixed station, the total efficiency is estimated by the author to be about 40 per cent., reaching to 50 per cent. under the most favourable conditions. As already stated, this was undoubtedly the case in the early days of electric traction, but it may be, and is, much improved upon at the present time.

The author points out as a counterbalancing advantage the fact that such a system of electric traction allows the dead-weight to be considerably less than with steam locomotives or similar appliances. The dead-weight of the electrical apparatus does not, he says, exceed, say, 150lb. per passenger capacity, and the whole weight of the electric car equipped for work is not more than double this.

He estimates also that the total fuel consumption in the power-house is about 7lb. to 9lb. per horse-power developed on the car axles, which is said to be equivalent to about ·5lb. per ton kilometre, or 5lb. per car kilometre—that is, in English measure ·8lb. per ton-mile or 8lb. per car mile. That this estimate seems too high, with well-designed plant, seems evident from the fact that a good compound locomotive only requires about ·06lb. of coal per ton-mile.

(To be continued.)

ELECTRIC TRACTION IN LONDON.

More than one inquisitive individual has wanted to know why it is that the Central London Electric Railway should run from Liverpool-street *viâ* the Mansion House and Oxford-street in order apparently to terminate in the *terra incognita* of Shepherd's Bush—a place that has the sound of country life in its title, but not very much of rural beauty in its actual surrounding. Answers to this question are many, and some are obvious. It might, for instance, be said that a railway is bound to stop somewhere: the Great Northern, *e.g.*, ends in a ploughed field near Doncaster, though connections with the North-Eastern enable the East Coast traffic to pass over the dividing line without the knowledge of travellers.

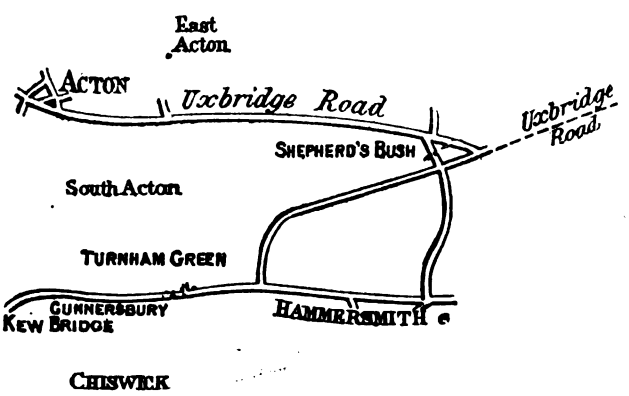
The Central London might, again, be said to end at Shepherd's Bush because there are two roads leading thence, under either of which the subway could extend with equal justice and possibility of good traffic. But whether intentional or not, the most important reason for making the western terminus of this line just beyond Uxbridge-road Station might fairly be considered to consist of the fact that from this point westwards there radiates a *surface line* or system of *tramways*. No one willingly travels underground if he can help it; and it was either a wise step or a happy coincidence that led the Central London engineers to end this line at the point where the tramways begin their suburban course. Passengers may then travel by the electric underground in a reasonable atmosphere for a long distance under crowded areas and streets where surface lines are impossible owing to dense traffic; then, at the journey's end, they come up to the daylight and complete their ride in the open air on the tramways. If this isn't the real reason why the Central London stops at Shepherd's Bush, then it might very well be so.

This locality may be, as above stated, a *terra incognita* to the average City man who lives south or east; but it need not be thereby considered a far-distant desert place. So far from that, it has a thriving population, more local industries than many other quarters of London, and serves as a market for Acton, Ealing, and the adjacent suburbs.

Ealing, as the readers of this journal will know, has just made itself rightly prominent for a well-designed installation of electric lighting both for private and public purposes; it is not a far cry to Acton, and the local authority of the latter district has now a splendid chance of distinguishing itself in such fashion as to rival, if not surpass, the neighbouring district. A rumour is current to the effect that the new interest which has lately taken over the West Metropolitan Tramway Company's system throughout this part of London proposes to double the lines—that is, to practically reconstruct them—along the Uxbridge-road from Shepherd's Bush to Acton. We feel that the opportunity—if the statement be well founded—is a most excellent one for the local authorities to oppose this project tooth and nail *unless the tramway company undertake to adopt electric traction* upon this line, and apply to Parliament at the same time for all necessary powers. The roadway is amply large enough along its entire length for the use of ornamental iron poles along the centre, upon which the trolley wires may be carried from brackets in the usual manner, whilst the local authorities would then be enabled to use the same poles for arc lamps by which to illuminate the roadway.

The traffic along a road of this kind is absolutely certain to increase rather than diminish, so that the comparatively slow speed, not only at starting but in running also, which is typical of ordinary horse traction, would soon prove an inconvenience to frontagers, passengers, and users of the road in general. A good and reliable form of mechanical traction may therefore be regarded as absolutely essential for this line; and taking the absence of grades into account, as well as the nearness of the Central London Electric Railway generating station, we can say with perfect safety that nothing could be found more suitable than the "trolley" system of overhead wires.

They should indeed make it a condition that the tramway company so arrange the line that this may be effected: it would mean a considerable saving to the ratepayers, accompanied by a great gain in attractiveness and value of the whole district. There would then be literally an electric road—above ground and below—the entire length of the way from Acton to Liverpool-street, so that for rapidity and ease of transit the inhabitants along the route would be the most happily situated of almost any in London. Already, we understand, some provisional steps have been taken to urge definite action upon the local authorities, and we trust that they will prove sufficiently wideawake to the chance now offered to show their appreciation of the advantages obtainable from electric light and power.



In the annexed diagram is shown an outline map of the principal roads in the district: that upon which electric traction thus has an opportunity of being installed is the continuation of the Uxbridge-road westwards from Shepherd's Bush to Acton. The line shown by dashes represents the Central London Railway terminating at this point.

HOW TO MAKE A DYNAMO EXCITE ITSELF.*

BY GEORGE T. HANCHETT.

Of all the minor difficulties which arise in electrical engineering there is none so annoying as the refusal of a machine to excite itself, or, as it is technically termed, "build." It often happens when the stockholders and parties interested have assembled to see the new machine start, and it invariably occurs if the district manager has been so injudicious as to invite gentlemen to whom he hopes to sell a machine, or has arranged to have the daughter of the president of the company throw the switch for the first time. In view of these facts the writer has collected various data on making a dynamo build, and adding some of his own ideas, has embodied the result in the following article, which he hopes may prove useful.

Series Machines.

A series dynamo will refuse to excite from any one of the following causes: (*a*) open circuit, a poor contact; (*b*) short-circuit, field magnets or armature; (*c*) bobbins so put on as to be opposed to each other; (*d*) incorrect connections; (*e*) insufficient residual magnetism. Inasmuch as it is more or less trouble to test out and correct these difficulties, it is wise to examine the symptoms carefully and make a thoughtful decision as to the nature of the trouble before applying the test and remedy.

(*a*) *Insufficient Contact and Open Circuit.*—This difficulty has often proved very elusive. It is to be carefully noted that a magneto bell is not a decisive test in such a case as this.

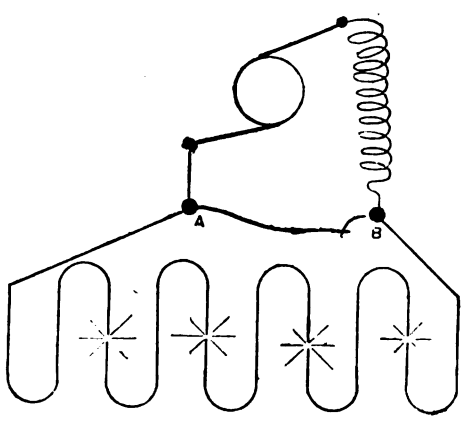

Fig. 1.

The initial magnetism of a new machine is apt to be very low, and the resulting voltage correspondingly so, perhaps, one-half a volt, or even lower. A magneto bell will ring quite briskly in circuit with a contact through which an E.M.F. of one-half a volt would be unable to establish a current sufficient to start the machine. Therefore be absolutely sure of the contacts by carefully inspecting them all. A loose screw or nut or a little lacquer under a contact may be responsible. This is a common difficulty with platers and machines of low voltage, but it sometimes occurs even on arc machines rated at 2,000 to 3,000 volts. Having made sure that the internal circuit is as it should be, obtain a good external circuit by short-circuiting the machine. This must be done very cautiously. It is wise to have the regular load in circuit, and establish the short-circuit, as shown in Fig. 1. A good method is to place a short piece of scrap wire in one binding post, and then with a suitable piece of insulating wire make contact between the other binding post and the short piece of wire. Should the machine build it will be at once evident by the sparking of the brushes. The short-circuit should then be removed and broken first where the two wires touch. The resulting arc will only burn the wire, and the binding posts of the machine will be uninjured. It is to be remembered that when a series machine is induced to build in this manner that it builds with a rush. It is, therefore, absolutely necessary to be able to instantly remove the short-circuit on the appearance of sparks at the commutator. Oftentimes a mere flying touch of the two wires is sufficient, and this should always be tried at first before a firm short-circuit is made.

* The *Electrical World* (New York).

(*b*) *Short-Circuited Field Magnets or Armature.*—It is evident that either of these difficulties deprive the field coils of any energy that may be generated, and so prevent the machine from building. Some series dynamos have a resistance in multiple with the field coils, and thus divert a portion of the current therefrom. When making a refractory series machine build, all resistances and controlling devices connected in this manner should be temporarily cut out by opening the derived circuit. Some series machines have a switch which short-circuits the field or armature. Be sure this is open. This seems a useless caution, but the writer has known of cases where it was not done, and considerable valuable time wasted looking for the difficulty elsewhere. Look for the simple things first.

(*c*) *Bobbins or Windings in Opposition.*—This defect rarely occurs unless the machine is assembled, and the bobbins connected when installed. To a man acquainted with the machine such a defect should be obvious at once. It may be discovered also by disconnecting and separately exciting each bobbin with a few cells of battery or other source of current. The resulting poles may be detected with a pocket compass. This will give sufficient information about the direction of the windings to properly connect them.

(*d*) *Incorrect Connections.*—It often happens that the loose cables and smaller parts of a dynamo are boxed separately. When the machine is installed, if these cables are put on by an inexperienced man they are almost sure to be put on incorrectly. A sketch of the connection should be, and is in most cases, sent with the machine, but even with this aid the inexperienced man is liable to go astray. Therefore look carefully to the connections of the machine.

(*e*) *Insufficient Residual Magnetism.*—This is usually the first cause to which the refusal to excite is ascribed, but it is scarcely ever necessary to excite temporarily from an outside source. A series machine heavily short-circuited will build on a very weak residual magnetism. If, however, it is absolutely necessary to excite the field separately to obtain an initial magnetism, the exciting current should be kept on for some time. It will also be well to pound the pole-pieces quite heavily with a copper hammer while the magnetising process is going on. This tends to more thoroughly saturate the magnets.

Shunt Machines.

A shunt machine will refuse to self-excite from any one of the following causes: (*a*) a short-circuit or a heavy load; (*b*) an open shunt circuit; (*c*) bobbins or windings in opposition; (*d*) incorrect connections; (*e*) insufficient residual magnetism.

(*a*) *A Short-Circuit or a Heavy Load.*—A shunt machine will not build under these conditions, for the reason that a very small fraction of the current generated goes to excite the machine. When the machine starts this initial current is very feeble, and if so small percentage of this already weak current is used in excitation, the chances are that it will not be sufficient to start the dynamo. Therefore in such a case see that the main circuit is open in order that the current generated may assist in building the voltage.

(*b*) *An Open Shunt Circuit.*—It is obvious that if the shunt circuit is open the machine will not build. Such a defect may often be located in the rheostat when a burned-out coil or a poorly-made connection may be the cause of the difficulty. It may often be detected by short-circuiting the rheostat. Sometimes the defect exists on the connections of the machine itself. Often the fault is in the rheostat wires running to the switchboard. The insulation of a wire will sometimes hold the two ends of a broken wire together so as to defy anything but the most careful scrutiny. Nothing but rigid inspection and testing of the entire shunt circuit will locate the difficulty.

(*c*) and (*d*) These have been discussed under series machines, and the same remarks apply.

(*e*) *Insufficient Residual Magnetism.*—In this case the expedient of short-circuiting the machine will only make matters worse. If it is possible to obtain a powerful outside source of current, the fields may be separately excited and the pole-pieces hammered as described under series machines. If such a current is not available, the

Digitized by Google

following device may be used with advantage: In Fig. 2 let B represent a few cells of Leclanché or Grenet battery. Three or four will answer. Let D represent the dynamo and F the shunt field. C is a knife plunge contact and X a fixed point. W is a weight tending to turn the switch, S, on its pivot, A, and make contact at C. It is prevented from doing this by a piece of 10-ampere fuse, X Y, which supports the switch. The battery is connected, as shown, in such a way that its E.M.F. will assist whatever feeble E.M.F. the dynamo may have. The dynamo starts and the combined E.M.F.'s send sufficient current into the field to build the machine. The voltage of the machine rises and the current in the shunt increases. The 10-ampere fuse being under tension fails at about eight amperes. The weight instantly closes the broken shunt circuit, and the batteries are thus automatically cut out before they are damaged by excessive current. A machine with eight amperes in its shunt circuit can continue to build without difficulty. At the time of cutting out the batteries their E.M.F. will be a very small fraction of the total, and the resultant current will be very little reduced thereby. It is important that the switch be just barely held open by the fuse wire so that the shunt circuit may be closed before the field magnets have time to discharge. The parts of the device are so simple that it is possible to construct it or its equivalent with almost any material at hand.

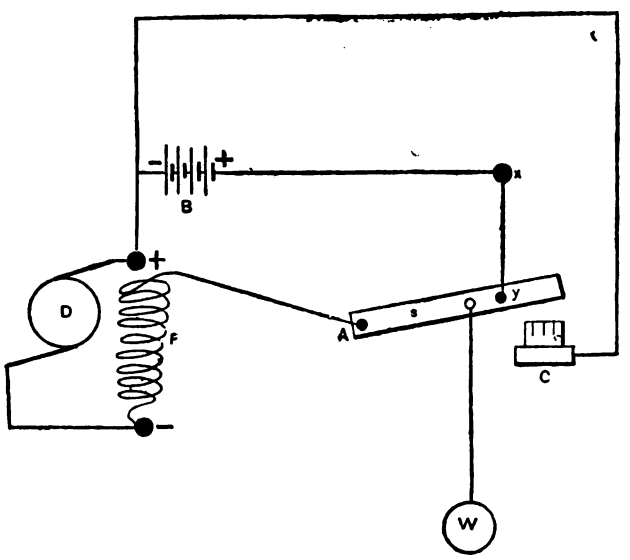

FIG. 2.

Some shunt machines require less than eight amperes for excitation. In such a case after the machine is built, the fuse wires, X Y, may be cut with a pair of pliers, and the batteries thus cut out and saved from further waste. It is not always known just how much current the shunt circuit of a machine requires, but a momentary current of eight amperes will not injure the ordinary battery. This method may also be used on compound and series machines, but it is hardly ever necessary. The writer has in the course of his experience encountered several cases where the men in charge did not give the machine time to build. Shunt and compound machines build very slowly, and especially so when first installed. In some rather exceptional cases it will take five or six minutes to bring the machine to voltage. A man in a hurry and somewhat excited in his desire to have things working properly is liable to try the machine correctly connected, and on its failing to give at once voltage sufficient to light the pilot lamps he decides that his connections are incorrect, and, shutting down, proceeds to change them, and thus incurs a long series of failures which a little patience might have avoided.

COMPOUND MACHINES.

These partake of the difficulties of both series and shunt machines, but they also have some that are peculiarly their own. A compound machine will refuse to build when: (*a*) the shunt circuit is open; (*b*) the brushes are heavily short-circuited; (*c*) bobbins are wound in opposition; (*d*) incorrect connections; (*e*) insufficient residual magnetism.

(*a*) *An Open Shunt Circuit.*—The machine may in this case build if a piece of light (No. 18 or 20) B. & S. copper wire be placed across the terminals. This will burn out, but still the machine will not come up to its rated voltage. This shows that the series coil is all right, but that the shunt circuit is open. Find and close this open place, and then make a quick short-circuit of the dynamo, as explained under series machines. In this case, however, it is not well to have the load thrown on. In case the series coil is so connected that it "builds down" the dynamo, this method will only tend to destroy what little residual magnetism there is. If, therefore, the machine refuses to build under this treatment, cross the series terminals and try again. If the dynamo still refuses to build with its field coils, all assisting each other and producing the correct polarity, look for faults (*b*) and (*e*) and apply the corresponding remedies.

(*b*) A heavy short-circuit at the brushes. This should be readily discovered and easily removed.

(*c*) This has been discussed under series machines.

(*d*) This also has been discussed under series machines, but, in addition, it is well to note that a compound machine has numerous studs and binding posts, and the difficulty is still more liable to occur.

(*e*) *Insufficient Residual Magnetism.*—This must be overcome in several ways. The magnets may be remagnetised through the shunt coils by an independent circuit, or the battery method explained on shunt machines may be used. Another very good method is to disconnect the series coils altogether, and separately excite them by a few cells of battery in such a way as to help the shunt coil. A storage battery is admirable for this purpose.

It sometimes happens that the machine will build properly, but that its series coils tend to reverse the polarity of the dynamo. This may be detected when the machine is loaded by short-circuiting the series coils. If the voltage rises in doing this the coils are in opposition, and the terminals of the series coils must be reversed. If the shunt is so connected as to "build down" the dynamo, the machine will refuse to excite till the terminals of the shunt coils are interchanged. In closing, it is well to note that it is perfectly possible to connect a field coil in such a way that it will tend to produce a polarity opposed to the magnetisation to which it owes its current. If all the coils of a machine be thus connected, it will refuse to build till the terminals of these coils are reversed. This is not confined to compound dynamos, but applies to shunt and series dynamos also.

THE PERFECTION OF THE ELECTRIC RAILWAY MOTOR.*

BY LINCOLN NISSLEY.

A study of the history of the electric railway motor shows us that, from the beginning up to a few years ago, there has been a great tendency toward complicated, fanciful, and impracticable designs, including outlandish forms of field magnets and unnecessary number of field cores and coils. In most cases also the mechanical construction has been very bad; the shaft being too small, the bearings being weakly supported, and the general workmanship poor and not up to standard. It has long been my opinion that the proper way to design a good railway motor is to consider very carefully and systematically each part, first by itself and then with reference to other parts, and thus collect and build up the elements which are best.

Let us now take up the various parts of the electric motor, and consider each as a simple problem in designing. The size of the frame should be such that it can readily be placed upon any standard truck. The machine should be completely shut in so as to make it thoroughly iron-clad. A good substantial iron-clad frame does more than anything else to give great stability and strength to the whole machine, and is highly desirable in a railway motor. The bearings should be directly and rigidly mounted in this frame, a simple fact that has often been disregarded,

* Abstract of a paper read before the Pennsylvania Street Railway Convention, Reading, September 5, 1894.

Digitized by Google

and all parts should be interchangeable. The armature and car axle should be in perfect alignment, and consequently perfect meshing of the gears is obtained, which experience has proved to be of vast importance. The gearings should be mounted closely to the frame, so as to eliminate buckling and tendency to loosen parts. The field magnets should be bipolar. The field should also be of the single magnetic circuit, rather than the consequent pole type, because the former is more economical in wire and current required, lessening the cost of renewals and repairs. A single circuit requires only 70 per cent. of the weight of wire, and 70 per cent. of the energy of magnetisation that is required by a double magnetic circuit. The field cores should, of course, be perfectly insulated; this can be accomplished with certainty by winding them on a solid spool of material which is firm and waterproof and highly insulating. The armature should be of the ring type, so that the winding does not slip out of place or pile out at the ends when running at high speed, a fact which will be appreciated by those who are operating cross country and suburban lines. The armature should have teeth or projections upon it in order to secure and protect the wires from mechanical injury, to reduce the reluctance of the magnetic circuit and the weight of wire and energy of current required to magnetise it. The perfect insulation of the armature core is of the utmost importance. The best material and the most complete covering should be used, and the greatest possible care should be exercised to avoid short-circuits, grounds, or broken wires. The efficiency should, of course, be as high as possible, and is made a maximum by reducing all elements of loss as far as possible. These losses are current to magnetise field, loss due to armature resistance, friction, resistance of air, and eddy currents. It has always seemed to me that if a machine can be run for several hours under full load without any part becoming overheated, the efficiency of that machine must be high. This fact is more absolute than any efficiency test can possibly be.

In looking over the past eight years of practice in the designing and perfection of the electric railway motor we have much to commend and considerable to condemn. The boldness of the achievements, the problems that have been solved, the rapidity of development, seem almost beyond comprehension. That the electric railway motor in less than eight years should reach the high state of perfection, economy, and efficiency that it has, as compared with the long years of development of the steam-engine, is remarkable. In the perfect railway motor we have something entirely different from what we have in the steam-engine. We have no reciprocating parts, but continuous rotary motion. The strains are all tangential, and this aids greatly in running and maintenance. The railway motor of yesterday is not what the railway motor of to-day or a few years hence will be. Yesterday we were struggling with difficulties connected with the commutator and brushes, which have been the great bugbear of all types of motors. Commutators and brushes require more care outside of gearing connecting motors to axle than anything else we have to deal with. They have always been the weakest spot in the electric railway motor. The question arises, can these difficulties be overcome? I think they can, and have been to a great extent already overcome by several of our large manufacturers.

In connection with the motion, we are labouring under very serious difficulties in regard to proper control and regulation. In the control of the railway motor we cannot do exactly as we do in the locomotive—adjust our point of cut-off so as to secure the best results with a given load. We have to govern our motors by varying the resistance in the circuit, which means loss necessarily, because the resistance has to be overcome to some extent by the current passing through it or by reducing the intensity of the field magnet, which also means loss; if this is true, then it seems to me that it is unfortunate, but is it necessary? I do not think so. The ideal railway motor for the propulsion of our cars would be a motor running at a continuous and uniform speed, and with a variable gearing, giving the motor the advantage of power when the car was first started. You all know that when our motorman wants to change the speed of his motor he moves a switch or controller handle around, which adjusts the current flowing through the motor. Now, as a matter of fact, the motor should adjust the current itself, and not the man, and the speed of the motor should remain absolutely constant, while for regulation between the motor and the gear on the driving wheels you should depend on varying the mechanical advantages entirely.

It should be borne in mind that it is less than three years since the first single-reduction motor was commercially introduced. The work was done under the most unfavourable circumstances. Compared with similar motors of to-day they were indeed crude and very costly. They answered the purpose, however, and it is generally admitted that they have been a financial success as compared with the use of former construction. The single-reduction motors have since been in continual operation, and those of recent manufacture, embodying the latest improvements, are a great advance in the onward march toward perfection. That there are still annoying circumstances in connection with the mechanism no one who is charged with the practical operation will for a moment deny, but inasmuch as they are universally proving a financial success, it may be taken for granted that electrical and mechanical improvements will be gradually introduced until they become as nearly perfect as anything of the kind can be. The question is not whether a motor is perfected, but whether it is enough of a success to warrant the improvements which will lead to perfection. Its advantages are not yet thoroughly appreciated, but they will be. Its future is assured; with this outlook will come better construction, better engineering, better mechanics, and the solving of the larger problems, which will place the perfected railway motor on a cheaper, better, and more successful basis.

ELECTRIC CABLES AND GAS-PIPES.

A legal case that has extended over two years has recently been decided by the Tribunal Civil de la Seine. As long ago as March 2, 1891, an explosion of gas occurred in the Larue Restaurant, Rue Royal, Paris, and this gave rise to an action between the Compagnie Parisienne du Gaz and the Compagnie Parisienne de l'Air Comprimé et de l'Electricité, the latter being generally known in this country as the Popp Company. From the report of the experts nominated to ascertain the cause of the accident, and to apportion the responsibility, it appears the conclusion arrived at was that the Popp Company had not sufficiently insulated its cables from the lead gas-pipes of the gas company and which were laid in close proximity to each other in the case in question. On the other hand, it was shown that the employés of the gas company had not kept a proper record of the warnings given to them, which, if attended to, would have allowed of the fault being remedied. From this it was urged that the responsibility for the accident, which resulted in injury to various persons, was divided between the two companies.

According to the judgment of the Court, it appeared from the experts' report that the original cause of the explosion was due to an escape of gas caused by a gas-pipe having been perforated. The gas entering a manhole of the Popp Company in the Rue Royale, passed through the service pipe carrying a branch cable for the electric lighting of the Larue Restaurant, into the cellar of the restaurant, where it became ignited at a light placed near the door of the cellar. It was found that the two holes through which the gas escaped from the gas-pipe had been caused by an electrical phenomenon, which had fused the gas pipe at two points where the cables had come into contact with the gas-pipe in the manhole. The enclosure of the gas-pipe in the manhole in proximity to cables carrying high-pressure current, the suspension of the cables without fixing them to the side of the manhole, and the negligence shown by not closing one end of the iron pipe carrying the service conductors into the cellar, and the fact of having in case of an escape of gas no outlet other than through the service pipe into the cellar, are

Digitized by Google

characterised as a serious mistake. The manhole was constructed by the Popp Company without any intimation being given to the gas company.

On the other hand, on the morning of March 2, 1891, the gas company's workmen were informed of a smell resembling gas having been noticed in the cellar of the Larue Restaurant. On their arrival on the spot at 2 p.m. no escape could be discovered; at 9 p.m. they were again informed of an escape of gas, but judged it useless to return at once. The Court held therefore that the company had failed in its duty, for carrying on a dangerous business they were bound to proceed at once to subscribers' houses on being informed of an abnormal fact. The inaction of the gas company, which, after the warning in the morning should have awakened their attention, was much to be regretted, as if the workmen had arrived about 9.30 p.m., or 10 p.m. at latest, they might have been able to prevent the explosive mixture from entering the cellar. The Court finally condemned the Popp Company in damages to the extent of 75 per cent. of the total amount, the gas company being mulcted to the tune of 25 per cent.

ELECTRIC POWER IN ENGINEERING WORKS.

The following is the presidential address delivered by Alderman Thomas Richardson, B.A., J.P., at the first meeting, held on Tuesday, of the present session of the North-East Coast Institution of Engineers and Shipbuilders:

Closely associated as I have been all my life with an engineering works started more than half a century ago, and increasing in size with the growth of the trade of the district until it has become one of the largest marine engine works on the North-East Coast, I have had by tradition and experience continually before me the difficulty of always keeping up to date with machinery and meeting the demands of labour, and great as this task often has been in the past, I can recall no time so discouraging and difficult as the present. We have had to contend with bad trade, with disputes between capital and labour, but I remember no period when we have had pressure from both troubles to contend with at the same time, making the successful carrying on of industrial concerns an impossibility.

Those of you who are directly associated with the engineering and shipbuilding industries will readily appreciate that the subject of economical production is one to which more than usual prominence has lately been given by the recent almost complete stoppage of work on this coast by one of those disastrous disputes between capital and labour which are now so frequent. It is not my province, as president of an institution such as ours, to dilate on the inevitable result of such disputes, but rather to seek for a counteracting element, in order to do our part in postponing the day when the industries with which we are connected will, instead of being in the proud position they were a few years ago, be crushed into comparative insignificance, if an end is not put to these suicidal conflicts.

Another factor which is year by year becoming more prominent is the competition of foreign countries, and the unfortunate doctrine which is so often sensationally made use of as to our superior capacity as handicraftsmen is by no means so true now as formerly. The extended and universal adoption of machinery has been the chief cause of this levelling up, and particularly is this the case in the engineering industry, where the scope for the application of machinery is practically unlimited.

It is not enough, however, to apply machinery, but to develop it, as the one remedy for survival is continuous evolution, although the unconscious fascination which is often associated with old tools and old methods often renders the evolution dangerously intermittent. It is apparently this fascination, combined with an unselfish desire to satisfy the cravings of the shipowner for propelling machinery requiring the least possible consumption of coal, which is responsible for the fact that whilst we build engines and boilers consuming 1½lb. of coal per indicated horse-power per hour, we drive the machinery in our workshops at an expenditure of fuel four to six times greater in amount. This is, of course, attributable to the use of a number of high-pressure non-condensing engines distributed over a large area, and supplied with steam through long lengths of piping from a central group of boilers. This, then, is a field in which economies are to be obtained, and one of the best solutions appears to be the application of electrical driving.

In the able address of Prof. Kennedy before the Institution of Mechanical Engineers this subject was very fully dealt with, and at the late meeting of the Iron and Steel Institute at Brussels a very interesting and instructive paper was given by Mr. Selby Bigge, which conclusively showed the importance and possibilities of the system. At the risk of rendering this address narrow, and more in the form of a paper rather than general, I propose to give some illustrations of the application of electrical driving, both in this country and abroad, hoping that a *résumé* of what has actually been accomplished may promote a discussion which will thoroughly ventilate the question and be fruitful in beneficial results. With the late disastrous record of the shipbuilding and engineering industries as an example, it is highly improbable that any capitalist will start a new shipyard amongst us, so that we may be sufficiently selfish to consider the application of electrical driving to existing works only. The first question to consider, therefore, is that having boilers grouped in one place from which steam is led to engines distributed over a large area, what economy can be expected from substituting those engines with electric motors supplied with power from a central station, and will the results justify the expenditure? We are all thoroughly aware that condensation does occur in steam in steam-pipes, and that the present engines are uneconomical; but a broad view is generally taken of the matter, and little has been done to ascertain what the results really are. It is for this reason that the experiments and developments made by Mr. Panton, of Messrs. Dorman, Long, and Co., of Middlesbrough, in conjunction with Mr. Selby Bigge, are of the greatest value, and particularly so as they have resulted in complete success. The original steam-driven machinery comprised punching, shearing, and bending machines, cold saws, etc., all of which were distributed over a large area and driven by six engines capable of indicating the following powers—viz, 27, 14, 14, 14, 16, and 9. These engines were disconnected and replaced by motors of 10½, 3½, 5, 3½, 3½, and 3½ horse-power respectively, the driving gear consisting of a belt from the motor direct to the flywheel of the machine. The most noticeable case is that where a large bending machine formerly driven by an engine having a cylinder 10in. diameter with a stroke of 12in. is now efficiently worked by a 3½-h.p. electric motor. The current for these motors is generated by a 50-h.p. Pieper dynamo driven by an ordinary horizontal engine, the steam being obtained from two Lancashire boilers which were already in use in connection with the steam driving of another portion of the works. Formerly the six engines in question were supplied with steam by two boilers, which are now dismantled, with the result of a net saving of 30 tons of coal per week and the entire labour in connection—stoking and upkeep.

Another striking advantage is that the speed of the motors being practically constant under all loads within their capacity, the machines driven by them are always running at the desired speed, and are therefore in a condition for producing the greatest possible amount of work. In reviewing this plant we have the advantage of ascertaining the approximate loss resulting from condensation in a long range of steam-pipes, and the working of small high-pressure engines under conditions usually found in ironworks and shipyards. It will be apparent, however, that the generation of power at one centre admits of an economy beyond this—viz., the use of a modern high-pressure triple-expansion condensing engine with a consumption of 12lb. to 14lb. of steam per indicated horse-power per hour, instead of a consumption of from 40lb. to 60lb., as frequently is the case at present. It is evident that the loss in such a case as that of Messrs. Dorman, Long, and Co. may be termed a maximum, on account of the machines working in the open air, and the steam-pipes led underground, but the results from ordinary cases of shop machinery are often sufficiently startling to warrant more attention being given to them than they usually receive. For purposes of comparison we will consider the results obtained from two works of about equal driving power, one having an electric installation and the other steam.

One of the most complete installations of electrical driving in the world as applied to large industrial establishments is that of the National Arms Factory at Liège, Belgium. These works were built in the year 1889, and are of very large extent, employing 2,000 hands, the daily output of finished rifles being 250. Some idea of the system adopted, and the value of machinery for economical and rapid production, may be formed when it is considered that there are about 58 parts in a complete rifle and bayonet, involving in their production about 750 operations; yet so great has been the development of machine tools used in this manufacture, that of the 750 total operations only 6 per cent. are performed by hand labour. Another feature is that a large percentage of the machines are automatic, and advantage is taken of this by placing several in the charge of one operative. The whole of the machinery is driven by electric motors receiving their current from one central dynamo coupled direct to a Corliss condensing compound engine having two cylinders and indicating 500 h.p. at 70 revolutions per minute, with a boiler pressure of 90lb. The auxiliary feed and condensing water is supplied by a pump driven by a 10-h.p. motor, receiving its current from the main generating dynamo, and placed on the canal bank 2,840ft. distant and 117ft. below the level of the engine. The water, after being used in the con-

denser, is discharged into a tank placed 40ft. high, from which it passes through finely-perforated pipes in the form of spray into an open reservoir on the ground level, and by this means is reduced in temperature so as to be again available for condensing purposes. The generating dynamo is placed between the high-pressure and low-pressure engines, and the armature being on the main shaft, acts as a flywheel. The armature, which is 16ft. in diameter, was constructed in place. The electromagnets are 20 in number, and there are 40 pairs of brushes, 20 on each side. The capacity of the dynamo is 3,000 amperes at 125 volts, and the makers guaranteed an efficiency of 90 per cent. The current from this powerful generator is distributed to about 31 motors, ranging from 3 h.p. to 50 h.p., placed in different sections of the works. The machines used in the manufacture of rifles are necessarily of light design, consequently the motors are arranged to drive line shafting only, and although the total length of main shafting exceeds 4,000ft., and the total length of belting is about 11 miles, there are no indirect main drives, a motor driving one line of shafting only, the object in view always being the reduction of loss by friction. Each motor is provided with an ammeter, and those in charge know the amount of power required to drive the machines when being worked to their desired capacity—any increase of that power at once indicates that there is a waste in friction, whilst any decrease indicates that the machines are not doing sufficient work; and when it is remembered that the revolutions of the motor are practically constant under all loads within their capacity, it is impossible to imagine an arrangement which so exactly fulfils the requirements of maximum economical production.

Compare this with the wasteful arrangements so common in shipyards and engine works, where engines, often already fully loaded, have to drive still another new tool, and the "make-the-best-of-it" policy of giving just a little later cut-off is adopted. The result generally is that the mean revolutions of the main shaft are not only decreased by any variation in load, but are, in addition, highly sensitive to the variations of steam pressure. This is, however, a diversion, and referring again to the Liège factory, there is also a 300-h.p. Willans engine, coupled direct to a dynamo, which generates the current necessary for recent extensions.

It has been found by careful experiment that the consumption of steam in the Corliss engine is about 14lb. per indicated horse-power per hour, whilst the losses are 10 per cent. in engine friction, 10 per cent. in the dynamo, 2 per cent. in lines, and 15 per cent. in motors, or a total efficiency of 63 per cent. at the motor driving pulleys of the indicated power of the generating engine. The whole of the electric installation was made and fitted by the International Electrical Company, of Liège, from the designs and under the direct superintendence of Mr. H. Pieper, the managing director and electrician-in-chief of the company, and we have an ample testimony of the efficiency of the entire plant in the fact that, although the works have been running over three years and a half, there has not been one single stoppage of the main dynamo during working hours, and no accidents of any kind whatever.

Particulars such as these are always of general interest, but any radical change made in existing works involve a very considerable outlay, and extreme care is necessary to be certain that such a change would be commercially successful. It is therefore essential in the first instance to ascertain what are the conditions existing at present; so we will take as an example an average old-established marine engine works, of which there are many in this district, the majority of them having been added to year by year to meet the demands of trade, and where extensions have generally been the result of a compromise between what was desired and what existing conditions would allow.

The works in question are steam driven, the boilers being arranged in one group, and supply steam at 60lb. pressure to 31 engines in different parts of the works. Eight of these are used for driving the machinery in the various sections of the works, and 23 are auxiliaries in connection with cranes, hydraulic pumps, and the like. The driving engines are of various powers and of designs which may be taken as representing a fair average of those used for the same purpose in similar works (Table I.).

No. 1 is a beam engine 50 years old, and is used for driving about 50 lathes, planing, slotting, and drilling machines of various sizes. With an average daily working load the indicated horse-power is 48 whilst running the shafting only, and with the machines all standing it is 17. Steam is supplied through 680ft. of piping, and the water discharged from an automatic steam-trap close to the engine stop-valve amounts to 270lb. per hour. The weight of steam used by the engine, and as measured from the diagrams at the average daily load—viz., 48—is 2,227lb. per hour, to which should be added 20 per cent. for moisture in suspension, thus making a total, including the water condensed in the steam-pipe, of 61lb. per indicated horse-power per hour. No. 2 engine is a modern two-cylinder horizontal, with variable expansion gear worked by the governor. The machines driven consist of two dynamos for works lighting, as well as a large number of average-sized tools. It will be seen from the table that the average working load when driving the dynamos is 93·8 h.p., but driving during the day the average horse-power is reduced to 38. Nos. 3 and 4 are single-cylinder inverted engines, and afford a good example of the wasteful effects of overloading. Nos. 5 and 6 are old-fashioned horizontal engines, in which the governor works an ordinary throttle valve, and both have been in use for about 30 years. Nos. 7 and 8 are small inverted-cylinder vertical engines running at 150 revolutions. The wasteful effect of this system of driving is shown by the consumption of steam, which averages 50·9lb. per indicated horse-power per hour, and to this has to be added the condensation in the steam-pipes, which is 7 per cent., bringing the total up to about 55lb. per indicated horse-power per hour, and even this is by no means exaggerated, as it is probable that the condensation in the pipes exceeds that indicated by the traps.

In comparing the two systems at this stage, and allowing 10 per cent. for engine friction in each case, and a total electric loss of 27 per cent. for dynamo conductors and motors, we require 45lb. of steam per effective horse-power at the main driving pulley of the steam installation against about 20lb. for the electric. Taking the total at 500 effective horse-power (which allows 125 average for the 23 auxiliaries) in each case, and an evaporation of 8lb. of water per pound of coal, the consumption of coal would be 36 tons per day for the steam and about 13 tons for the electric. In the steam installation under consideration the water is obtained from the waterworks main at considerable cost, whereas under similar conditions with a condensing engines the cost would be much less.

Another feature of value is the reduction of labour, which for stoking alone would be about one-half, whilst still further reduction could be made in the engine driving and greasing staff, as whilst steam-engines require constant attention, the motors could be practically left to themselves except for starting and stopping, as should anything go wrong with any motor it would be immediately detected in the central station engine-room by the indicator corresponding to the particular motor at fault. It will be evident that we have dealt with the greatest source of economy by the concentration in one highly efficient plant for the generation of power for the whole of the main driving of the machinery of the works. It will be interesting, however, to consider the relation between the power at the main driving pulleys and that absorbed by the machinery in doing actual work. Referring again to the driving engines, 1 to 8 (Table II.), it will be seen that the loss in driving the shafting,

Digitized by Google

belts, pulleys, etc., range from 25 to 70 per cent., or an average for the six engines of 43 per cent. These experiments have been confirmed by some made by Mr. Westgarth, and referred to by him at a meeting of the Cleveland Institution of Engineers. Mr. Westgarth found that in an engine and boiler works he experimented on that of the total power developed by the steam-engine 59 per cent. was absorbed by the shafting and gearing, and in one of the workshops where two long lines of shafting were used for driving a comparatively small number of machines the power absorbed was 75·6 per cent. of the total. In another workshop where the shafting was well laid and rope gearing used for the main drives the percentage was 42. The average of the whole experiments is therefore about 50 per cent. Consequently it appears that half the mean power would be saved if all the machines could be driven by independent motors instead of by line shafting. This in an existing engine works is, of course, impossible; but there are many instances where long drives may be divided with great advantage, whilst the independent driving of large tools would be another very desirable feature.

An example of what may be termed ideal electrical driving is that of the Bedson Wire Company, of Middlesbrough, where the installation is the most perfect and complete that has as yet been attempted in this country. Every process connected with the manufacture of wire is carried out by means of electricity, the wire drawing, galvanising, spinning, and barb fencing machines, overhead and locomotive cranes, hydraulic pumps, induced-draught fans, lathes, centrifugal pumps, are all independently driven by electric motors. Owing to the entire absence of shafting and belting, the construction of the building is very light, and the convenience of the whole plant is most noticeable. The current is generated by a 600-h.p. dynamo driven direct by a three-crank triple-condensing engine with boiler of 160lb. pressure. A special tunnel, 350 yards in length, has been constructed for the conveyance of the conductors, and branches are taken from these to the 50 motors, which vary from 5 h.p. to 40 h.p. each. The lighting of the works is most complete, the greater part being carried out on the inverted arc principle, which is so perfect that there is an entire absence of shadows. The original plans for driving these works electrically were prepared by Mr. Selby Bigge, who appears to have given considerable attention to the question of electric driving. Before definitely deciding to put down such a novel plant several experiments were necessary, for which purpose special machines were designed by Mr. Bedson, the managing director of the Bedson Wire Company. These experiments were made at Liège by Mr. H. Pieper, and were so successful that after an exhaustive series of tests the directors of the company decided to adopt the electrical installation in its entirety.

A novel feature in connection with the boilers at Messrs. Bedson's works is the application of Messrs. Ellis and Eaves's well-known system of induced draught. This is the second application of the system to land boilers, the first having been made at the Atlas Works, Sheffield, originally arranged with Lancashire boilers. These have gradually been replaced by 10 single-ended boilers of the marine type, the advantages claimed being as follows: (1) considerable economy compared with the Lancashire boilers with Galloway tubes; (2) considerable reduction in space occupied; (3) absence of smoke; (4) greater elasticity of power.

In ordinary work, by maintaining a vacuum of 3in. at the fan, the combustion is at the rate of about 35lb. per square foot of grate surface, and one single-ended boiler can readily evaporate as much steam as three Lancashire boilers 27ft. by 7ft., with ordinary chimney draught. Where the demand for steam varies in a works, the system is a great inconvenience, and this is especially the case for electric light installations. It is evident that with this system of draught, or with any other efficient system, the assumed consumption of 13 tons per day could be still further reduced.

From the comparison which I have made we may fairly conclude that the saving gained by the substitution of electrical driving in an old-established works would be considerable. Whether this saving would justify the outlay in all cases would have to be settled by those who have their capital invested in works suitable for its adoption. I may say, however, with reference to the firm of which I am a member, that for some time we have had the matter under consideration, and the various investigations and experiments made by Mr. D. B. Morison, and of which are those enumerated in this address, have so convinced us of the commercial possibilities of the system that we have now on order a small plant prior to further developments hereafter.

I have endeavoured to confine myself in my remarks to a plain statement of what has been accomplished by making use of electrical power to drive machinery, and have not gone into any of the possibilities the future may reveal. We have known the science of engineering to advance at times, as it were, by leaps and bounds, and from the rapid strides that this comparatively new energy has made within the last few years, we may have reasonable expectation of still further development in this direction.

In the address which I have given to you this evening, I feel that I have but inadequately fulfilled the task imposed when you conferred upon me the honour of electing me president of this valuable and widely-known institution, but hope that my remarks will be productive of help in the work before us. That the suggestion of the possibility of further expenditure of capital is unpalatable to many members of this institution I can well believe, seeing what dark clouds are hanging over us, but let us hope that, as in past times, the clouds will have a silver lining and shortly disperse, giving place to the pleasant sunshine of renewed commercial prosperity of which both capital and labour will receive their just and fair proportion.

TURVEY'S TESTING SET.

In the annexed illustrations is shown the testing set introduced by Mr. W. Turvey, of 101, Campden Hill-road, Notting Hill-gate, W. The resistance-box, represented in Fig. 1, has been devised to meet the demand for an accurate and economical resistance box. Every attention has been given to all essential points, and at the same time all unnecessarily expensive parts have been eliminated. The blocks and plugs are carefully fixed and fitted, and are made from specially hard brass to withstand wear, and the plugs are fitted with milled ebonite handles, and are mounted on a dull finished ebonite slab, which is plainly engraved with the values and conections. The coils are of platinoid wire wound on brass bobbins, and are most accurately adjusted to the marked values in Board of Trade units at 17deg. C. There are four pairs of proportional coils and 16 resistance coils; the total resistance being 11,110 ohms, thus enabling resistances from ·001 to 10 megohms to be measured. The outer case is of polished mahogany, lined with baize and fitted with lock and handle. All the tests, etc., described in the various test handbooks can be readily performed by means of this instrument.

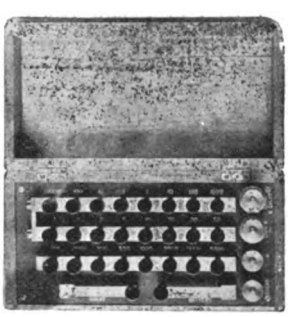

FIG. 1.

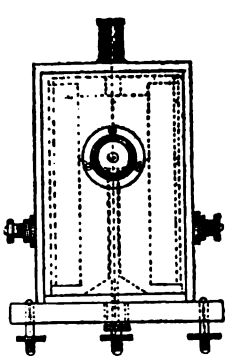

FIG. 2.

The galvanometer, which is shown in Fig. 2, has been specially designed for use with the resistance-box mentioned, but it can also be employed for any purpose for which a highly sensitive and dead-beat galvanometer is required. It is of the permanent magnet type, with powerful magnets. The coil has a resistance of about 250 ohms, or more or less as required, and it is fitted in an aluminium tube, and suspended by means of a phosphor-bronze strip, which can be easily replaced should it ever be necessary, and one coil can be exchanged for another in a few seconds. The mirror is a concave one of one metre focus, and is rigidly attached to the coil in such a manner that the silvered surface is exactly in line with the axis of suspension, and when not in use the coil can be clamped by simply turning a milled head, thus relieving the suspension of all strain. The terminals are both insulated from the case, and the instrument is exceptionally steady and well made. To these instruments Mr. Turvey has given the name of the "Electrical Engineer" resistance-box and galvanometer.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

'SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

'THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
ther Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIII. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

ARE WE QUITE SATISFIED?

Dr. Kemna, when addressing the Municipal Engineers at Antwerp, paid a high compliment to English engineers. He said: "English engineers have specially shown a spirit of daring enterprise and a well-marked practical turn of mind." As a rule, engineering practice has been very successful, but there have been some well-known failures, and a good deal of "try another tack" to get over this or that difficulty has gone on before, in some instances, success could be recorded. It may be that the "spirit of daring enterprise" has in some matters electrical led our engineers along doubtful paths, and many of us are not even now quite satisfied with existing tendencies. To come to the practical point. Is there not a too great spirit of daring enterprise, not to say an extreme rashness of spirit, in permitting many central stations to depend so entirely upon everything going right? Of course it is difficult to suggest that any particular part of the apparatus, be it boiler, engine, dynamo, or distribution plant, should go wrong. You cannot put your finger upon *the* weak point, otherwise it would soon be less weak; but weak points must necessarily exist, and should be looked for. The contrary, however, is the practice, and too often disaster more or less acute follows the breakdown of a weak spot. There is hardly a man in many stations but fully understands the risk of a breakdown at any moment. Yet too many engineers, eager to do something, advise a more or less temporary installation, which must and does run at great risk of breakdown. These breakdowns come periodically, and do considerable damage to the industry. Everyone who knows anything of the matter sees the foolishness of such action, but those who know little or nothing of electrical work imagine that such breakdowns are inevitable. Hence the reason why men in authority so often taunt us with "being in our infancy." Is not this delusion fostered by the daring spirit we have emphasised? Carefully consider some of the smaller, yea, even some of the larger stations, and the fact must strike the most casual observer that success depends upon everything going right. There has been no thought of a possibility for one small link to fail. All the eggs are in one basket, and these eggs are usually placed there by engineers who arrogate to themselves all the knowledge of the universe and relegate to others an equal amount of ignorance. Although at the risk of being misunderstood, we must again call attention to one phase of English practice which tends to perpetuate this evil—it is the non-employment of a competent engineer. In a somewhat sarcastic way we referred the other week to weak specifications, and specifications whose only object seemed to be to aim at the compulsory adoption of this or that patented apparatus. While some specifications err in this direction, others err in allowing the contracting parties all manner of license. This kind of specification shows that the consulting engineer is, as a rule, incompetent, and relies upon the contractor to get him out of his difficulty. This rule, however, is not universally true, for

Digitized by Google

we know of undoubtedly competent men who rely too much upon the contractors, but then the contractors know that they know their business, and that anything cheap and nasty, unreliable, and inefficient would be immediately condemned. It is different with the incompetent man: the contractor can and often does take an advantage which detracts from the value of the installation.

RULES FOR WORKMEN.

Almost every electrician-in-charge frames rules and regulations for the men employed upon the installation. These rules are not always as comprehensive as they might be, and though fatal accidents have been few in number, a good many men have received shocks they would rather have avoided. In a good many of these cases the shock has been received through a direct infraction of rules, some through carelessness, and some because there existed no rule to direct attention to the danger. Mr. J. Ayer, of St. Louis, has drawn up a fairly complete set of rules to be followed by the employés of the Municipal Electric Lighting and Power Company, of that city. These we give elsewhere, as although they may require many subtractions, as well as many additions, to make them cover the practice in this country, they do form such a set of rules as ought to be in the hands of every employé of every central station in this country. We purpose hearing the criticisms of chief electricians upon these rules, and then issuing the amended rules in pamphlet form so that they may be placed in the hands of workmen. A large proportion of the circuits in America are overhead, and these we imagine are more dangerous to the workmen than the underground mains more prevalent in this country. The large number of central stations so rapidly coming into use will find employment for many workmen, and these have to be educated by the chief electricians—a task requiring for a time very constant supervision. It will therefore assist them if they are able to obtain an exhaustive set of rules, and we trust the nucleus we give in this issue will lead to what they require.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

CLASHING ADDRESSES.

SIR,—As it has come to my knowledge that a Mr. V. Newport, styling himself electrical engineer, of Messrs. Newport and Holder, is issuing business cards bearing my address—viz., 23, Sherwood-street, Piccadilly-circus, London, W.—without my permission or authority, will you kindly insert this note in your next issue, so that if it catches the eye of Mr. Newport, he can alter his cards. I am sorry to trouble you, but I do not know Mr. Newport's private or business address.—Yours, etc.,

October 16, 1894. GEORGE WILSON.

Telephony in Hungary.—The local authorities of Jász-Berény intend to establish telephonic communication between the various towns and villages of the district, the chief central station being situated in Szoheck.

CITY AND GUILDS OF LONDON INSTITUTE.

LECTURE VI.—THE CONSTRUCTION AND ACTION OF ELECTRIC BELLS, THE ARRANGEMENT OF BATTERY CELLS, AND OF CIRCUITS FOR BELLS.

(Specially contributed.)

I have arranged a bell circuit on the board, and you see it contains four different pieces of apparatus. These are the battery, B (Fig. 1); a push, P; a bell, C; and the connecting wire, W. In many bell circuits another piece of apparatus—the indicator, I (Fig. 2)—is used.

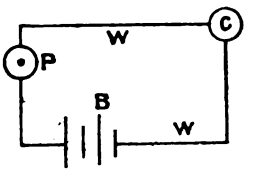

FIG. 1.

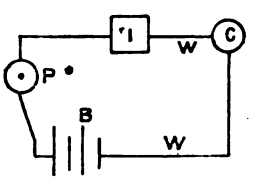

FIG. 2.

Let us begin our investigation with an examination of the battery. We must look upon a battery in electrical work somewhat as we look upon a pump in hydraulic work—namely, a piece of apparatus to enable us to maintain a difference of pressure in a circuit and thus to obtain a current of electricity. We can examine the various parts of one of the cells, several of which are connected together to form the battery. Here is a cell similar to those in the battery.

Leclanche Cell.—This consists of an outer containing vessel of glass, Fig. 3, inside of which is a small cylinder

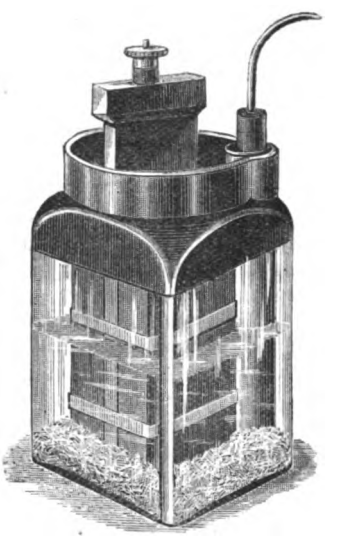

FIG. 3.

of zinc, Zn, and a porous pot fitted with a strip of carbon, C, surrounded by peroxide of manganese and coke. This mixture is tightly packed round the carbon strip, and kept in by a layer of melted pitch at the top. The liquid you see is a solution of sal-ammoniac in water.

Polarisation.—Before examining further into this form of cell, we will examine a still simpler one. Here

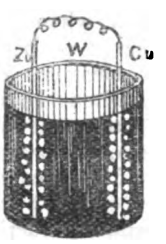

FIG. 4.

I have an ordinary glass jar, Fig. 4, containing a strip of zinc, a strip of copper, and a little dilute sulphuric acid. I throw the image on the screen, and connect the

Digitized by Google

strip of zinc to the strip of copper by this wire. Immediately the connection is made you see the liquid, as it were, especially around the Cu strip, starts into bubbling life. Thousands of bubbles are formed. These grow in size, and escape from contact with the metal, going up through the liquid, and burst at the top. With suitable apparatus we could collect the gas which forms these bubbles, and should find that it was hydrogen. The investigation of this phenomenon, however, is not just now my purpose, but I want to point out that these gases evolved upon the surface of the plates interfere with the normal working of the cell. If the plates in the original clean condition would maintain a definite difference of pressure, or E.M.F., the Cu, when covered with the gas bubbles, will not maintain so great a difference of pressure.

The combined actions may be likened to two opposing forces. The resultant of two opposing forces is their difference. Thus, if two forces act—one, say, of 100lb. in one direction, and one of 50lb. in the opposite direction, the resultant is as if only one force of $100 - 50 = 50$lb. was acting in the direction of the greatest force.

Well, the action of the Zn and Cu is to push up an E.M.F. in one direction, and the hydrogen film, being opposed in the cell to the zinc plate, gives rise to a counter E.M.F.; so that when the cell is polarised the acting E.M.F. is the difference between these two opposing tendencies, and is smaller than it would be could the plates be kept perfectly clean.

This phenomena of the action of the gases which collect on the plates is called *polarisation*.

The experiment with the two metals and the one fluid in the glass shows you the action of polarisation, and I may tell you that similar polarisation takes place with the Leclanché cell. This renders such a battery unsuitable for constant work, but when the work is light and intermittent as in bell work, the battery has a chance to recover itself. We shall see directly how this defect through polarisation has been overcome in other designs of battery. At present, however, we will examine the battery we have here a little closer.

Energy.—If I pump water to a height I have to expend energy in so doing, for work is done, and whenever work is done energy is expended. When I personally raise and lower the pump handle muscular energy is consumed, and this muscular energy is maintained by the changes which take place in the food consumed. We may look upon the food as being chemically consumed in the body. Just the same if the pump is worked by a steam-engine—the energy can be traced back to the consumption of coal in the boiler furnace. Again, if it is electrical energy that is used, and has to be maintained, we must look for the chemical consumption of something. In most batteries the energy is obtained by the chemical consumption of zinc. It is so in this Leclanché battery. If I weighed the zinc rods when first put into the battery, and weighed them again and again after use, I should find the weight gradually decreasing in proportion to the work I called upon the batteries to perform. It does not take long to see visible signs of their being eaten away. The source, then, of our electrical energy in this circuit is to be found in the chemical consumption of zinc in the cells. Chemists symbolise zinc, copper, and carbon thus: Zn for zinc, Cu for copper, C for carbon, and in our diagrams we may well use these symbols.

Maintaining Pressure.—To return to our Leclanché cell: you may assume that when the combination of zinc, sal-ammoniac, and carbon is properly made, there is thus obtained a difference of electrical pressure, or an E.M.F. This E.M.F. is greatest when the cell is doing no work—when it is upon *open circuit*—that is, when there is no external conductor connection between the zinc and carbon, or when the resistance of that connection is infinite. If we connect the zinc and carbon by means of a conductor that has very little resistance, practically no resistance, the plates are said to be *short-circuited*, so that

open circuit means practically infinite external resistance,

and

short circuit means practically no external resistance.

When we have a reservoir of water, so long as the water has no channel by which to flow away the head is constant, but directly we open a channel or channels the water runs away, and the head of water is lowered. If we want to keep the head of water constant at its highest point with the channels open, we must have a pump or some means of obtaining that head; and so we have to expend energy obtained from somewhere to maintain this difference of pressure.

When the electric cell is properly made, then the E.M.F. is like the head of water—constant and a maximum. Use the cell, and we must maintain the E.M.F., and we do this in the Leclanché cell by burning the zinc. Thus, you see, the burning of the zinc is necessary to maintain the difference of pressure, or E.M.F.

Further, if I employ a steam-engine to keep up a head of water, that steam-engine will not enable me to get an infinite difference of level or a head of water infinitely high. A given steam-engine only allows me to get a given head. If I want a higher head, I can use a second engine to help the first, and if the height obtained is still insufficient I can use a third or a fourth. You will see at once that the height is increased only if the engines help each other.

Just the same with my electrical apparatus. One cell will only allow me to get a certain pressure, but I can supplement this by using a second, a third, a fourth cell, and so on till I get a sufficient pressure.

Mr. Kempe, in his pocket-book, gives the following table as the E.M.F.'s of various cells:

Name.	Volts (approximate).
Grove	1·96
Bunsen	1·96
Fuller bichromate	2·14
Leclanché	1·60
Daniell	1·07

In order to obtain a greater E.M.F., I have to arrange the cells so as to help one another to raise the E.M.F. Cells so arranged are said to be in series. Here are four cells, Fig. 5, making a battery so arranged. You see the first zinc

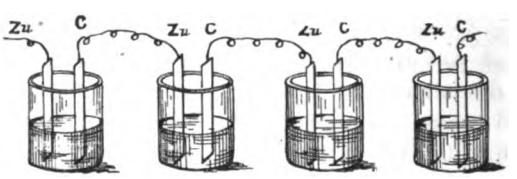

FIG. 5.

on this side is left free to connect to the external circuit, then the first carbon is joined to the second zinc, the second carbon to the third zinc, the third carbon to the fourth zinc, and the fourth carbon is left free to join to the external circuit.

The pressure is assumed to act in all cells from the metal consumed towards the other metal, and in this instance we look upon carbon as a metal. Hence in the battery shown the pressure acts from the first zinc to first carbon, and so on; the current, when any, also flows in the same direction.

If E represents the E.M.F. of one cell, then 4 E represents the E.M.F. of these four cells, and n E represents the E.M.F. of n cells similarly connected.

Recalling Ohm's law,

$$C = \frac{E}{R},$$

where R indicates total resistance, we may for the moment modify this formula, and let R represent total external resistance, and r total internal resistance, and so write

$$C = \frac{E}{R + r}.$$

If, however, r represents the resistance of one cell, then the resistance of n such cells in series is represented by $n\,r$, and we can write the formula

$$C = \frac{n\,E}{R + n\,r}.$$

Digitized by Google

Using cells in series, then, adds to the internal resistance. Usually we require all possible E for use in the external circuit, and so desire the internal resistance to be as small as possible, so that as little E.M.F. as possible may be used in overcoming this internal resistance. This necessity for keeping the internal resistance low may modify the arrangement for cells, and there is still another cause which may modify the arrangement. Once more consider the reservoir of water. To maintain the head of water, the pumps have to supply as much water as the channels carry away. Now, a particular pump or set of pumps may be able to keep up a required head if the quantity to be supplied is below a given limit. If the quantity required is above that limit, then another pump, or more pumps, will be required to assist in obtaining the quantity; and these additional pumps must be so arranged as to give that quantity at the given head or pressure.

Ohm's formula becomes, when there is no external resistance,

$$C = \frac{E}{r};$$

and if there are n cells in series with no external resistance it is

$$C = \frac{nE}{nr}.$$

From this we see that adding cells in series when there is no external resistance does not advance us with current, for

$$C = \frac{E}{r} \text{ is equivalent to } C = \frac{nE}{nr}.$$

What I have previously said about resistance is applicable to internal resistance as well as external resistance. We may take the sectional area of the internal resistance as equal to the sectional area of the opposed strips of metal. Thus, in Fig. 4, we may suppose the Zn and Cu strips to be similar in all respects as to size, and take the surface area of one of the opposing faces of the metals as the sectional area of the liquid resistance between them. If we double this sectional area, we halve the resistance just as with a piece of copper conductor. Hence, increasing the opposed surfaces of the strips decreases the internal resistance. So, also, does bringing the strips closer together, for that diminishes the length of the resistance. It is not always convenient to increase the size of the opposing strips, but we can obtain the same result by joining the similar strips in two or more similar cells.

	1	2	3	4	
Cu	——	——	——	——	Cu
	1	2	3	4	
Zn	——	——	——	——	Zn

Suppose the lines represent respectively the Cu and the Zn opposed in four similar cells. Each cell has a resistance, r. If now I join the four copper strips to each other, Fig. 6, and the four zinc strips by good conductors having

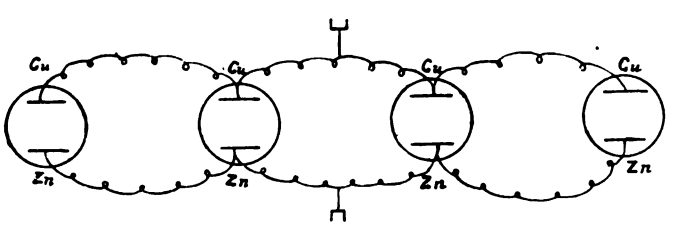

FIG. 6.

a negligible resistance, then the combined cells act as one large cell, giving the E.M.F. of one cell, but having one-fourth the resistance of one cell, or a resistance $= \frac{r}{4}$.

Cells joined up in this fashion are said to be in parallel.

Joining cells in series increases the E.M.F.

Joining cells in parallel diminishes the internal resistances of the combination.

It is easy to combine these ways of joining up, or to arrange the cells in *multiple series*.

THE CHLORIDE ELECTRICAL STORAGE BATTERY.*

The Franklin Institute of the State of Pennsylvania for the Promotion of the Mechanic Arts, acting through its Committee on Science and the Arts, investigating the chloride electrical storage battery, finds as follows:

The sub-committee appointed to conduct this investigation has had this battery under careful consideration for a number of months, and has investigated the several features which are claimed to give it merit. During the larger portion of the time a number of cells have been in possession of the committee, and have been placed upon a regular working circuit under the control of one of the committee's members, where they have been subjected to exactly the same usage as a number of other storage cells of other makers and of the same size, so that opportunity was thus given to obtain the results of the performance of the chloride storage battery in regular use, which is ultimately the final test by which the utility of all inventions and improvements must be measured.

The results of this examination have led to the opinion that this battery embodies certain features of construction which prove it, both theoretically and as verified by use, to be a distinct improvement over hitherto known forms of storage batteries. In order to fully appreciate these features of improvement, it will be necessary to recapitulate, briefly, a few well-known facts regarding storage batteries in general.

In all lead storage batteries, one of the objects desired is to obtain a large lead surface for small mass, as the capacity and discharge rates are strictly proportional to the amount of surface involved. This necessary maximum of surface has hitherto been obtained in one or two ways. The earlier way was to slowly eat out the lead plates by electrolysis until they had attained the requisite spongy condition, an affair of some time and expense. The later way—and the one which is generally practised—is to cast a frame of lead, with raised right-angled ribs on each side, thus forming little depressed squares, or to punch a lead plate full of holes, which squares or holes are then filled with a pasty mixture of red oxide of lead in positive plates, and with litharge in negatives.

For several reasons cells made in this way have always given more or less trouble in service. In the first place, after continued use or during heavy discharges a greater or less amount of mechanical disintegration of the positive plates would often take place, small fragments of lead and lead oxide dropping down between the positives and negatives, short-circuiting them and often causing further and more serious break-up, buckling, and sulphating. Even when these particles are prevented from falling, their mechanical looseness causes poor contact with their supporting lead frame, thus entailing increased internal resistance and heating with diminished output. This disintegration appears to be due largely to the fact that the lead oxide paste placed in the holes is a mechanical rather than a chemical mixture, and hence that in changing from PbO_2 to $PbSO_4$ during the action of the cell, the molecules being only related to one another in a fortuitous manner, are easily broken up and thrust apart in the change of volume attending the chemical action. This, of course, seriously limits the life of a battery and its utility for public service.

In the chloride battery, it is claimed, and the committee's investigations go to confirm the correctness of the claim, that the method of construction is such that this disintegration is far less liable to occur. This mode of construction is as follows:

Instead of cementing lead oxide paste into or against a lead framing in order to obtain the necessary active material, the latter is obtained by a strictly chemical process. Lead chloride is taken, mixed with a given proportion of zinc chloride, and this mixture is then fused and cast in small squares in suitable moulds. When thus cast, the product is of whitish colour and vitreous character, being quite brittle.

For the negative plates, these blocks are about ⅛in.

* Being the report of the Committee on Science and the Arts on the invention of Clement Payen. Issued from the Franklin Institute, Philadelphia, March 29, 1894.

Digitized by Google

square and $\frac{5}{16}$in. thick, and are cast in groups of four, these groups being united by portions having, say, $\frac{3}{32}$in. to $\frac{1}{8}$in. thickness. For positives, the fused mass is cast in separate lozenges, each lozenge having a bevelled V-shaped periphery. These cut squares or lozenges are then placed in a suitable mould, and a molten mixture of lead and antimony, in proper proportions, is cast about them under high pressure, thus fixing them securely in a firm lead framing of somewhat more than the usual density. (The feature of casting under pressure is an improvement in manufacture, due to Mr. H. Lloyd, who is connected with the American makers, and the process is protected by patents granted to him). The connecting sheets of the squares making up a group, and the V-shaped bevel of the lozenge, serve to make their solidity of fixation exceedingly good.

The frameworks containing the chloride castings are then placed in a dilute solution of zinc chloride, together with plates of zinc, the frames and zinc plates being alternated with one another and in metallic contact. This combination is the equivalent of a primary battery "dead short-circuited." The chemical reactions which occur result in the removal of the zinc chloride and the chlorine of the lead, and there remains finally the dense framing containing squares or lozenges of spongy lead, which plates are then "formed" in practically the usual manner.

If a section of the spongy lead thus made be examined, it is found that the metal is in a crystalline condition, and that the crystals are all uniformly arranged with their longer axes perpendicular to the surface of the plate. This provides interstices, so that the changes of volume occurring in the chemical reactions of electrolysis may take place without exerting lateral pressure upon the crystals, or otherwise crowding them into a condition of break-up. These crystals are not, of course, mechanically and irregularly bound together, but are related to one another according to the laws of molecular formation, and are consequently much more strongly bound together than if they had been mechanically combined.

Furthermore, this crystalline structure presents the maximum obtainable surface for the given mass, an infinite number of inter-crystallic channels passing all through the material and the entire plate being of the same thoroughly spongy consistency, except in those small portions where the continuous lead framing is encountered.

The effect of this extreme porosity and surface area is to give the battery a maximum capacity for a given weight and size of cell, an item of great importance when considered with reference to the demands of traction. Very heavy discharges also can be taken from this battery, owing to the interstices between the crystals permitting changes of volume to occur without mechanical violence to the structure.

While the method of construction just described seems to accomplish its anti-disintegrating function perfectly, it has been thought best by the manufacturers, in order that there shall be no doubt about the matter, to introduce between the plates a thin sheet of acid-proof fabric, so that any small particles which might fall away could not make metallic contact with two adjacent plates and thus short-circuit the cell. The fabric chosen for this purpose is woven asbestos cloth. It might be thought that the introduction of this asbestos would considerably increase the internal resistance of the cell, but the fact is otherwise, the resistance of the cell being not appreciably higher than that of other lead cells.

This is undoubtedly due to the fact that the larger part of the resistance of most lead cells is that caused by poor contact between the lead framing and the paste placed in it. In the chloride battery this contact is exceptionally good, owing to the pastilles of chloride being so firmly bound by the framing cast under pressure as to compensate for any resistance due to the asbestos.

These batteries are, and have been for several years, operating successfully and in very large numbers in the city of Paris as a source of current for lighting purpose. A large plant has been in operation in this city in the building of the Provident Life and Trust Company for a year past, and a very large one has been installed at the station of the Germantown Electric Light Company, where it is said to have given, thus far, entire satisfaction.

The manufacture of this battery is protected by a large number of patents of the United States and of foreign countries. The essential features of the process of manufacture, however, are covered by the patents granted to Mr. Clement Payen.

Believing that this battery is a noteworthy and meritorious improvement upon many other forms of lead battery, tending to greater durability, greater capacity without increase of weight, and making possible heavier discharges without injury, the institute, therefore, recommends the award of the John Scott legacy premium and medal to Clement Payen, the inventor.

ELECTRIC TRAMWAYS AND TELEPHONE WIRES.

The question as to what is the best method of protecting telephone lines from injury by the working of electric tramways is again discussed in the *Elektrotechnische Zeitschrift*, Dr. V. Wietlisbach, of Berne, taking up the subject in that journal of October 11. The writer reminds us that the disturbances caused in telephone operation by electric tramways are both electrical and mechanical. The first mentioned are noticeable by noises in the telephones and the difficulty of understanding conversation, and the second by the two networks coming into accidental contact, resulting in the fusion of wires and possible damage from fire.

The electrical disturbances are set up in the first place by the strong current passing along the rails to earth, entering the telephone appliances *vid* the earth wires of the telephone system; and secondly, by electro-dynamo induction of the parallel carried lines. Another effect of the current passing along the rails is the electrolytic action on gas and water pipes. This difficulty has been overcome in Switzerland by the arrangement of a copper wire 7mm. to 8mm. thick (of the same strength as the contact wire) near the track. This wire is connected to the rails at intervals of at most 100 metres, and with the generator at the power station. Experience has shown that by the use of this wire the so-called roaming, or "vagabondising," as Dr. Wietlisbach puts it, currents are completely removed, at least from telephone wires. For instance, notwithstanding the fact that in Zurich a large number of telephone stations, with their "earths" generally connected to the water-pipes, is situated in the immediate neighbourhood of the electric tramway, no noise is heard in the telephones. As is known, this noise causes interruption in those towns where there is no return wire, but where the rails are provided with earth-wires. By the use of the return wire, the electrolytic action of the current on the iron and lead pipes laid in the ground is to a large extent removed.

It is not so easy to overcome the effects of induction as that of a current distributed along the rails to earth. Experiments made by the author with the Zurich tramways and telephones showed that a noise arose with a parallel arrangement in the same street for a distance of 500 metres of both conductors separated by a distance of 10 metres, the disturbance rendering the comprehension of conversation difficult.

As a result of his experiments, Dr. Wietlisbach comes to the following conclusions: (1) that the parallel arrangement of single telephone wires only for a length of 100 metres in the same street as an electric tramway is excluded; (2) that with the loop system the parallel method is practicable for about five kilometres, although all wires along the route must be looped; (3) that long lines, especially those connected with other long lines, are best carried another way; (4) that crossing is not injurious if not too often repeated, and if it is effected in a suitable vertical distance from the contact wire. The author finally discusses the subject from the mechanical point of view.

Electric Lighting in France.—The local gas company at Angers, which has a monopoly for gas lighting until 1929, is being asked to introduce the electric light into the town. The railway station at Niort has been installed with the electric light.

MONOCYCLIC ALTERNATING SYSTEM FOR SIMULTANEOUS LIGHT AND POWER WORK.

The issue to hand yesterday of the New York *Electrical Review* for October 10 contains a long article dealing with a monocyclic alternating system for simultaneous supply of light and power introduced by the General Electrical Company, of that city. This method has been devised for the distribution of alternating currents for lighting with incidental power, and our contemporary considers that this system is the most recent and most promising innovation in the electrical power transmission field. To it has been given the name monocyclic, and it constitutes a complete central-station lighting and power system. We quote the following from our contemporary:

The system takes the place of the well-known high-frequency system in central-station work, operating transformer systems, and distributing networks in the same manner, with the additional advantage of being able to supply the current to motors by means of a balance wire, which is carried only to places where the motors are to be used. The principal advantages attained by the monocyclic system are the following: It can operate incandescent and arc lamps and motors in parallel from the same generator, and even from the same transformer; it solves the problem of the operation of alternating-current motors which has for so long proved the *bête noire* of the electricians—the motors employed being not only equal but claimed to be superior to continuous-current motors in their constancy of speed, great simplicity, and absolute reliability, commutators, collector rings, brushes, or moving wires, being entirely absent. They can be started at full load with normal current. By the flexibility of voltage incident to the use of the transformer it is able to operate low-tension networks on the Edison three-wire system in the same way as the continuous-current lighting system, and even with the use of the same overhead or underground mains. It affords a better balance and entails less expenditure of copper by replacing the heavy low-tension feeders with high-tension primaries of much less cross-section feeding into the mains by transformers.

It offers the same simplicity as the ordinary alternating-current system, and differs from it only in its ability to operate high-grade motors by means of the third wire, which is similar to the neutral wire of the Edison three-wire system. It allows perfect operation of the whole system of the generators in parallel, the whole lighting and power station being operated from three 'bus bars, only the third 'bus bar being provided for the supply of current to the motors. By the use of two transformers, three-phase, quarter-phase, or any other type of alternating motor may be supplied with current. The low frequency of 7,200 alternations per minute used with this system reduces the effects of line inductance, and is consequently favourable to transmission over long distances. The generators and motors are both slow speed, and for both generators and transformers are claimed an efficiency and regulation never before attained.

As above said, the lighting system is operated in the same way as in the old alternators by two wires and one transformer, which supplies a two-wire or Edison three-wire system from its secondary terminals. From the same mains, however, motors are operated, and in this case two transformers are used, connected between the main wires and the supplementary or power wire; in which, by the action of the motors, an intermediate but laterally displaced voltage is established and maintained. For this purpose the generator armature contains besides the main coil a small supplementary or teaser coil, which is connected with one end to the centre of the main coil, while the other end is led to the third collector ring. It is obvious that this third collector ring is used only for supplying motors, while the lighting current passes exclusively through the main collector rings, and that the third or power wire needs to be carried only to where motors are located, and, since it does not convey large currents, needs to have a small cross-section only.

The frequency for the monocyclic system has been fixed at 7,200 alternations, or 60 cycles per second. This frequency is better adapted to the general requirements of incandescent lighting than any other, since higher frequencies occasion inductive effects in conductors which more than outweigh the advantages gained in reduced transformer cost, while with lower frequencies the increased cost of transformers is a serious objection. For arc lights also this frequency is very desirable, since we cannot go much lower without having an unstable arc, and since increased frequency increases the humming which is caused by all alternating arcs. At 7,200 alternations this noise is inappreciable. Besides, this frequency gives a convenient number of poles in motors at moderate speeds, and is consequently well suited to power work, while at the same time it allows the operation of generators running at about one-half the speed of the old high-frequency alternators.

For very long-distance work occasionally a frequency of 33 cycles per second, or 4,000 alternations per minute, is used—33 cycles have been chosen in this case as being 10 per cent. higher than the lowest frequency at which incandescent lighting is still perfectly feasible. In general, however, 60 cycles per second, or 7,200 alternations per minute, are preferred as standard frequency.

The alternating-current generators have been designed with all the qualities requisite constantly in view. The reliability of the machine is increased by the care bestowed on the insulation, which renders the use of high voltages possible. The number of armature coils has been reduced, and these coils are machine wound, insulated, and afterwards slipped into the armature slots; thus they are easily replaceable. The generators are compounded for constant voltage under all loads, or over-compounded up to 15 per cent. to take care of the drop of voltage in the line.

The bearings are both self-aligning and self-oiling, running with scarcely a tremor and exceptionally cool. Most of the machines can be arranged for direct propulsion by high-pressure waterwheels, the large units lending themselves readily for direct coupling to turbines. All the generators have a commercial efficiency of at least 90 per cent., rising to 95 per cent. in the larger sizes.

The transformers employed in the monocyclic system are designed for frequencies between 33 and 60 cycles, and have as high an efficiency as the standard transformers. Thus they can be operated not only at the standard frequency of 60 cycles, but also in those cases where for long-distance work 33 cycles have been chosen. All these transformers are oil insulated.

Sub-station transformers have also been designed for power transmission work where the transformer units may be banked in groups of large output. These are more particularly suited for step-up and step-down work, and for all sub-station distribution. They are without oil insulation. They are thoroughly ventilated, and each bank is provided with one or more ventilating blowers passing a draught of cool air through them. The efficiency of these transformers is very high, notwithstanding the decreased frequency, owing to the care used in the selecting of the iron, and ranges from 96·5 to 98 per cent., and even higher in very large units.

All the low-frequency alternators are fitted for use as synchronous motors, and will run up to speed under light loads without the use of clutches or starting motors. They have as synchronous motors the same high efficiency as the generators, will run in absolute synchronism with the generators, and will stand very heavy overloads without falling out of synchronism. They also possess the valuable property of compensating for the loss of voltage by the self-induction of the line and for idle currents, by their action as condensers.

As our readers are aware, an induction motor is one with a closed-circuited armature having no connections with the supply circuit. Such a motor, however, can with a simple alternating current of the old type of machine not start of itself from rest under full load without excessive current. This difficulty has been overcome in the new monocyclic motor, which in its action is essentially identical with the best three-phase motors built. It has a closed-circuited armature wound with a small number of heavy copper bars

Digitized by Google

of low resistance, and a starting rheostat is placed within the armature spider. At starting, the coil sliding along the shaft is kept out of contact with the switch used to short-circuit the resistance, but when the motor is approaching full speed the contact ring is moved along the armature shaft until the armature is short-circuited on itself. Thus a very large starting effort is obtained with the current limited to a reasonable amount by resistance.

In all the standard induction motors the starting resistance is adjusted so as to give a starting torque 50 per cent. in excess to the running torque at full load, and requiring, therefore, an excess of 50 per cent. of current over full-load current.

The field winding of the motor is very similar to that of the three-phase induction motor, with the difference, however, that only two of the three terminals are connected with each other and with the teaser coil of the generator by the intervention of transformers.

WORKMEN'S RULES

[The following are the rules and regulations adopted at St. Louis. We give them complete, and ask our readers to criticise, so as to be able to obtain a set of rules suitable for English central stations.—ED. *E. E.*]

INSTRUCTIONS AND CAUTIONS.

1. Do not handle any electric light apparatus while you are standing on the ground.

2. Never use both of your hands while handling dynamos, or anything pertaining to same, while said dynamos are being used.

3. Do not touch a water-pipe, iron post, or any stone, brick, or iron structure while in contact with a lamp, line, dynamo, or anything connected with the electric light apparatus at the same time, unless you are provided with rubber gloves and other insulating material, which the Municipal Electric Lighting and Power Company has declared to you to be necessary and sufficient to fully protect you from accident by the electric current.

4. When your business necessitates your going through the station, keep as far as possible from the machinery and belting, and do not meddle with anything unless you are ordered by the man in charge, and then only after receiving careful instructions.

5. No one is permitted to in any manner work on the switch-boards except when directed so to do by the man in charge of dynamo-room, and then only after receiving careful instructions.

6. Keep away from the lightning arresters and wires leading to them.

7. Linemen or others operating on lines must handle each and every wire at all times as if it were charged with the electric lighting current and grounded.

8. When obliged to pass over, or under, or by an electric wire, avoid touching it in any manner, and especially with any uncovered portion of your person. Damp or wet clothing makes chance contact with wire dangerous.

9. Tools used by linemen and others who have occasion to work on lamps or apparatus which may be charged with the current, must have handles well covered with rubber or other insulating material, and it shall be the duty of every lineman to look after his tools and see that they are in good condition for use, and especially as to the insulation of the handles.

10. If it is at any time necessary to stand on the ground or any surface not insulated from the ground while handling electric wires or apparatus, heavy gum boots or an insulated stool must be used; and under no circumstances allow yourself to make contact between two or more wires at the same time.

11. Lamp trimmers and others engaged in taking care of and trimming lamps must see that the switch on the board from which the lamp hangs is closed before they proceed to handle the lamp. Instruction laid down in Article 3 of these rules must be observed in connection with the work of handling the lamps.

12. In the event of anyone in any manner being caught on live wires, where it is possible to get to them, pull the one caught away by grasping any portion of his clothing or body protected by clothing. There would be no possible danger to the one rendering help, no matter where you might be standing. If the one caught should be on a pole or ladder, he could usually release himself by kicking himself loose from the supports, or drawing up his knees, thereby causing the body to fall. It is understood that employés will wear and use their safety belts when working above ground on poles or ladders, especially when handling wires.

13. Rubber gloves, rubber insulating materials for tools used by employés, and other protective articles will be found in the store-room. Employés have every access to these goods at all times through the storekeeper. They should examine their gloves and the insulation of their tool handles daily, and if they discover any defects therein, return the same to the storekeeper, and select themselves perfect tools in place thereof. No charge has been made or will be made for goods thus exchanged. Employés who have been provided with tools must return them on leaving the service of the company, or the cost of the tools will be charged against their account.

14. Any employé known to violate any of the above rules, or disobey any of the instructions or cautions, thus endangering his own life or the personal safety of others, will be immediately dismissed from the service, if complaint is made at the office.

GENERAL INSTRUCTIONS.

1. All employés are requested to report anything of interest to the company which they may learn, whether in their department or not, so that the best results may be obtained at all times in all departments.

2. All instructions which follow must be read and observed by all employés, wherever they may apply to any work they are required to do, whether designated for the government of the department they are in or not.

3. At the station, papers and books are supplied relating to the business, and you are urged to spend an hour or two using them when you can.

4. All necessary line tools that you are required to have will be furnished by the company on application to the storekeeper, except pliers, connectors, climbers, screwdrivers, belts, and other similar small tools. These tools all linemen must own. If desired, they can be purchased of the company, and on leaving they can be returned and the money will be refunded. All tools above mentioned issued by the storekeeper will be charged and deducted from your pay.

5. Do not use defective tools or appliances, whether yours or those of the company. If you have defective tools, ladders, or other appliances, you are hereby ordered not to work with them, and no foreman or others must be regarded who instructs you otherwise.

6. A written report of all accidents, whether to persons or property, wherein this company could possibly be interested, must be made on the accident blanks and forwarded to the office as soon as possible after the accident occurs.

LINE WORK.

When cutting wire, grip the line with the cutting jaws of the pliers and move up and down at right angles with the wire two or three times, so that you cut the insulation part of the way round on both sides; then hold your pliers firmly, bend the wire once or twice up and down with your left hand and the wire will break. Never try to break the wire by twisting your pliers, unless you first move the line out of the cutting jaws. There is no excuse for nicks in the cutting jaws of Stub's pliers, and careful linemen rarely have it happen.

7. In stripping the ends of wire to make a connection, always cut along the wire towards the end, in much the same manner as if whittling a stick. Never cut round the wire with the edge of the knife or pliers, except when cutting the wire.

8. In making joints, be careful never to let the cutting jaws or edge of your tools "score" the wire. If you do, don't cover it up, but make a new joint.

9. After a joint is made with not less than four turns each side of the connectors, dip or moisten with acid. If you are on the ground, dip the joint in melted solder and hold it there a few seconds to thoroughly heat the joint, then take it out. If well "tinned," dip it in water to remove any acid which may be on the ends of the wire near the insulation.

10. If where you cannot dip the joint, but have to use the ladle, pour the solder frequently over the joint until it leaves a thin, smooth coating on the wire. It is not properly done if the solder is in lumps or on in a thick layer.

11. If you are obliged to use a "blow pot," hold the joint in the flame until the solder will easily melt when held against the wire after the flame is removed. When this is accomplished, apply the solder with the flame and not before.

12. Solder is put on the joints to keep them from corroding, thereby ensuring good contact where the two wires come together, and is of no use if not well applied.

13. After the joint is well cleaned of acid after being soldered, paint it thoroughly with insulating compound, then cover with a layer of tape, which you will start on one side of the joint, against the insulation of the wire, but not over it. Have the first layer cover the joint and bare wire only. When this is done, paint it, then start back over the joint and tape until you have run over the line insulation about 2in., then wrap two more layers, painting each when done.

14. In wrapping tape, cover what you have half, or lap one-half. After four layers are on, paint the whole thoroughly.

15. Whenever you find a break in the insulation on the line anywhere, paint it first, then tape and paint it. Don't forget this.

16. In "tying in," never draw the tie wire so as to bend a kink in the line or cut through the insulation with the tie. A tie will properly hold the wire in place without drawing it so tight as to do either.

17. In using pulley blocks on the line, avoid the use of "come-alongs" when possible by taking a series of half-hitches, or making a "noose-wrap" with a small line on the wire to hook the block to. If you do use "come-alongs," see that you do not score, cut, or kink the wire, and always paint and tape broken insulation.

18. Groundmen are especially cautioned to watch the line in "paying out," and prevent "kinking." Should a short kink get pulled into the line, cut it out rather than take the risk of its breaking, though you should straighten it out.

19. Never use porcelain knobs where exposed to moisture or the

Digitized by Google

weather, and never use them anywhere else if glass can possibly be used.

20. Porcelain knobs circuit-breaks may be used where necessary, providing not more than two lamps are on the loop. In making them, paint and insulate with tape the joints in connecting wire of loop.

21. In making house connections where wires enter building, be sure to have not less than 6in. clearance from cornices of walls. All wiring running over cornices or other building projections must be protected with rubber tubing, thoroughly taped and painted at the end. Never let a wire, however well protected, come in contact with any outside portion of the building.

22. In placing tubing on wire, carefully paint and tape at the upper end, leaving the lower end open, so that moisture could escape if it got in.

23. Always run wires in straight parallel lines, and make square turns where possible. Twelve inches between wires is the proper space for arc lighting circuits, where practicable.

24. Never fasten a cut-out box against the wall. Always place glass or porcelain knobs between the box and the wall.

25. Never fail to put in "drip loops" in line where entering building.

26. In all electrical work, remember where insulation is desired it can never be too good, or when contact is desired, you can never make it too good or strong.

27. In removing lamps ordered out, always close the loop at the line where it was originally cut in, and remove all dead wire. Never leave dead or unnecessary wire in circuit.

28. Always use iron pins on arms where wires turn a corner or leave the line.

29. Never screw an insulator on iron pin or bracket very tight, nor without first putting inside the glass a strip of paper folded twice or three times. This will prevent the glass being broken, as iron expands with heat nearly twice as rapidly as glass, and unless there is room enough, the difference in temperature between winter and summer would burst insulators in summer which were placed in winter.

30. In connecting line to lamps hung from suspension wire, put on safety loops by making a half-connection with a short flexible wire on each side of the insulators at the pole and on the lamp hood. Solder and tape same as other joints. Arrange the length of wires leading to lamp so the lamp will not shadow the roadway of either street.

31. No joints are to be permitted to be made and left without being soldered.

32. When working on an arc circuit, always keep it closed, unless you are able to have it tested O. K. during the day from the station at one o'clock, and from three to four, or as agreed with the chief inspector.

33. When placing guard wires on street crossings always use iron pins and glass insulators to attach both ends of guard wires to. Never tie on cross-arm on pole. In stormy weather, when they may be of use, they would be dangerous every way.

34. In working on lines all circuits must at all times be regarded as alive and grounded. With the hundreds of miles of wire throughout the city, some of which are carrying heavy current at all times, many using ground return, the line you are on may "come alive" at any time—be careful.

35. Always avoid temporary work. It is your orders at all times to do what you do thoroughly.

36. When working on poles, be careful to stand so, if you should slip or get a shock, you would fall on your belt rather than on the wires.

37. Avoiding leaning over or crowding through wires when possible, and do not put yourself in a position where you would fall on wires, should an accident occur.

38. Always in making connection on poles, work from below rather than above, when possible.

39. Examine cross-arms and see that they are sound and firmly fastened before trusting your weight on them.

40. Always report anything found defective, especially cross-arms or poles.

41. Be careful that all tools are securely fastened in your belt when working on pole or ladder, and, in handling wires and lines on poles, have a proper regard for the safety of those walking or driving below.

42. When working on poles, always use your safety belt, as well as other safety devices which you are requested to use. It takes but a little time to make yourself safe, and many weeks to mend a broken bone.

43. Never lay tools down when above the ground.

44. The company demand that you take the necessary time and precaution for your own protection and that of others at all times.

TRANSFORMER WORK.

45. In placing transformers and making connection for same, you will always leave the line connection where you branched off to be made after all other work is completed. The primary fuses at the transformer must be left out until the final line connection is complete.

46. In making connections to constant-potential (alternating or 500-volt) circuits, always finish one connection before breaking the insulation on the other line. Remember this: that you must have but one wire or joint bare at the same time when working on the lines.

47. After completing a transformer connection, and before closing line connection, carefully paint the entire outfit (except glass insulators) with insulating paint.

48. See that all wires leading out of transformers and out of fuse-boxes are well taped and painted where they leave the transformers, and all transformers must be placed so far from doors, balconies, windows, and other openings, and sufficiently high above ground and roof as to prevent accidental contact—in other words, out of reach.

49. All secondary wires from transformer to house should be as well insulated and protected from ground as if carrying high-pressure currents.

50. In plugging brick or stone buildings, paint the plugs with insulating compound before driving them.

51. All supports for transformers and fuse-boxes placed on buildings must be well painted with insulating paint.

INSPECTOR'S SPECIAL INSTRUCTIONS.

1 At all times when on duty your carts must be supplied with rubber gloves, boots, coat, and hat; also pliers, connectors, climbers, jack straps and vise, safety belt, hand axe, insulated stool, magneto, two or three brackets and glass, tape, carbons, line wire, jumpers, and hand-line.

2. Inspectors away from their carts, or those not provided with carts, are requested to have and to use their necessary safety devices and clothing where handling lamps or lines.

3. In working on lamps or lines, always regard the line as grounded and alive, whether it is or not. Observe this rule in hunting trouble on "dead" circuits. They may be "O. K'd" at any time by others and the current put on without a report from you. They may also cross up elsewhere with live circuits.

4. Report to their headquarters as soon as you can any trouble discovered on the lines of other companies, and report dangerous conditions existing to the City Lighting Department if you are in doubt as to the ownership.

5. Avoid interference with foreign wires where possible, but if you find the lines of other companies so situated as to be dangerous to the public, do what you think is right, and report to the owners and to this company by nearest telephone and make written report as well.

6. In the event of injury to persons or property by the wires or appliances of this or any other company, where the electric current could possibly be the cause, investigate fully and make full written report to this company only. If trouble was the result of cross or dead or broken wires, find out how the cross was made, how the wire was broken, to whom the wires belong, the names of witnesses and parties damaged in any way; in fact, report all you can find out and find out all you can.

7. Report by telephone, day or night, to the general manager any serious or unusual trouble as soon as practicable.

8. All repair work where material is used must be reported on a separate slip.

9. In putting on jumpers be careful that the loop of jumper does not lie on wire below, to make a cross possible if the insulation does not hold.

10. All inspectors when away from the plant are requested to report by telephone as often as practicable. All inspectors must report as often as once an hour during their entire watch, especially if on trouble.

11. Inspectors must report by telephone to plant any repair work to be done by linemen which has been occasioned by temporary work while on watch.

12. Mounted commercial inspectors must remain at the office when not out with their horses on regular duty.

13. All mounted inspectors must keep their carts as near their work as possible when out; at other times, at the station or office, and remain there themselves.

14. In addition to reporting by telephone when out, report to station at the time you go off duty, notifying the one in charge that you are off and that you will be off after that time.

15. Record on telephone sheet any call for extra service, and report same to office on properly signed blank form No 3.

16. No extra service will be furnished except by instructions from chief of dynamo department or the office.

17. In clearing trouble of any kind, where temporary work only can be done by you, make a full report on separate trouble slip, so that it can be properly repaired later. Unsoldered joints, broken insulation, bracket work on poles or similar troubles, as well as defective pins, cross-arms, poles, windlass-boxes, etc., should be reported separately.

18 Maps of alternating circuits, showing locations of branch cut-outs, must be carried by all inspectors.

19. Inspectors can find separate maps at station or office, which they can take with them if necessary.

20. All items of interest relating to the condition or operation of the plant in any manner you are requested to report.

21. Always be gentlemanly to customers and to the public.

22. Always wear your uniform and badges when on duty.

23. Always leave memorandum at station where you are gone.

INCANDESCENT WORK.

24. You must at all times be supplied with a complete supply of fuses. Exchange your wallet once a week or oftener, if necessary, for a full one.

25. In renewing fuses be sure that the binding post screws which hold the line wires are firmly set. Fuses are frequently blown by loose line connections.

26. When primary fuses are blown, examine transformer for short-circuit or leakage before replacing them.

27. When main-line secondary fuses have blown, test with the current for ground if circuit is being used; if not, test with magneto bells, first removing both fuses on main block and testing wires to lamps only.

28. In fusing primary circuits only, observe the following. Never fuse transformer with larger fuses than the following.

Digitized by Google

120	,,	,,	80	,,	
150	,,	,,	100	,,	
200	,,	,,	130	,,	

30. In placing fuses on secondary circuits, always open the switch on the branch being fused, or turn the lamps "off" at sockets before replacing fuse.

31. When replacing fuses, always test for grounds or short-circuits on lines where fuses are blown.

32. Use your fused testing wire for all tests on secondaries if testing with current. When grounds are found, unless cleared by you, the branch grounded must be left cut out and the office notified.

33. If grounds or short-circuits develop on house wires, inform the owner and ascertain if he wants the company to correct the fault at his expense. Report to the office by telephone, if necessary, what trouble is found, and the owner's name, unless you locate and correct the fault. The usual report in writing will be necessary.

34. Always cut out entirely any faulty transformer and report by telephone at earliest moment in the daytime, so as to allow as much time as possible to change it.

FIRE RULES.

35. Record all fire alarms on telephone blank, and when location is discovered, examine the maps, so that you may be familiar with the locations of the circuits in the vicinity should a second alarm call you out.

36. When out, if you discover a serious fire, go at once and see if our lines are likely to be in the way.

37. In answering second alarms always report to the police captain and the fire chief on your arrival, and inform them where you will likely to be found about the fire.

38. If the supervisor of city lighting is on the ground, render him any assistance you can.

39. Don't neglect the company's interest at any time for that of others.

40. Save any property of the company in or near burning buildings only when you can do so without risk to yourselves.

41. Be of such service to the fire chief as you can, so far as it relates to your business.

42. Avoid cutting wires when possible, and arrange to renew the service as soon as possible if you do cut them.

A thorough knowledge of the circuits will enable you to do your work easier and in a more satisfactory manner to yourselves and the company than if you fail to acquire this. Study the maps.

DYNAMO DEPARTMENT.

1. The number of lamps on each circuit must be recorded on the circuit-board each day.

2. All new city lamps and circuit changes will be made on map-board and must be noted in this department.

3. All station employés are requested to study the circuit maps and become familiar with the locations of the different circuits.

4. On receipt of telephone or other message to cut out any circuit for the protection of life and property, do so promptly. On an arc circuit, always run the brushes up before pulling plugs on switchboard. On incandescent, by cutting in resistance at switchboard to kill the dynamo; then open the switch.

5. When a live circuit opens during a run, the dynamo must be cut out at once and left out until the trouble is located and O. K'd. by linemen or inspector.

6. Circuits ordered open must be marked on board with coloured chalk. All other circuits must be marked "O. K," with white chalk. This must be done only by those authorised so to do, and must be reported to man in charge in dynamo-room.

7. Never "try" a circuit with dynamo that opens during a run, until the trouble is located, no matter if it "rings" closed.

8. Never connect dynamo to a circuit on which men are at work, without instructions from the men to do so.

9. When an arc light or motor circuit is reported "O. K." after it has been open, build up current very slowly at dynamo by hand, and take about five minutes to put full current on, because it frequently happens that linemen will leave their work and start out on a circuit looking for trouble, without first notifying the station. By starting the circuit in this manner, should they be in a position where they might feel the current, they would likely have warning before current reached a dangerous intensity.

10. Never run two machines in series. Doing this will be sufficient cause for dismissal. No excuse will be accepted for disobedience of this rule.

11. Rubber mats and gloves must be used when working the switchboard. The same rule applies to work on dynamos when running.

12. An arc made by electricity can frequently be blown or whipped out with a towel, on continuous-current circuits, and should be extinguished in that manner if the connections which occasion the arc cannot be easily separated.

13. In the event of a short-circuit on alternating lines or switches in station, the current can be safely shut off by cutting in resistance on exciter at switchboard.

14. Water will not extinguish an electric arc or fire when produced only by the current.

15. Large canvas covers are available, which should be quickly spread over the dynamos if water is used to extinguish fire on the floor above.

16. Fire-buckets must be kept filled with both sand and water on each floor in machine building above engine-room. In many cases sand will prove more useful than water in extinguishing a fire. The hose on each floor must be kept connected and ready for use.

17. In using sand or water remember that a little well directed is better than quantities thrown wildly. Use no more of either than is absolutely necessary, as it is easy to do more damage with them than would be likely by fire.

18. Any faulty lamps, wires, belts, or anything else reported to this department must have immediate attention from the man in charge.

19. Always report to the general manager by telephone, at his office or residence, anything whatever which he should know. Do this promptly.

20. None but employés are permitted in the building without a pass. Men in charge are requested to respectfully enforce this rule.

21. Smoking is absolutely forbidden.

22. Always record all telephone messages.

23. Read all other rules, part of which apply particularly to this department, and a knowledge of them is required of you.

SHAFTING FLOOR.

1. Permit no one here except on business.

2. Do not approach the shaft between the pulleys while it is running, particularly that portion of the shaft where clutches are carried, except when it is necessary to examine the bearings. Then be careful that you have plenty of clearance between your body and the edge of the running pulley or clutch mechanism.

3. You must not wear loose or flapping clothing. Be careful that your sleeve does not hang down and that your jacket is worn buttoned.

4. Notify the dynamo tender in charge if a belt is flapping or jumping too much, or of any defects in the belts. Should a clutch slip, notify him, so that it may be thrown out if possible until it can be cared for.

5. Never clean shafting while it is running.

6. Examine daily your grease-cups and see that they are in working order, and be sure that all standing pulleys on running shafts are well lubricated. Before examining these, inform the dynamo tenders, so that they will not throw the clutch in while you are about the pulleys.

7. Keep your machinery clean and your floor free from dirt.

8. All towels, clean or dirty, must be kept in the cabinet provided for them.

9. The hose on this floor must always be connected ready for use in case of fire, and fire-buckets must be kept well filled.

10. In the event of fire avoid throwing water on belts. Use as little as possible on account of injury to belts and machinery below.

11. Report immediately to engineer on duty any machinery which appears defective or in any manner out of order; also make written report of same to chief engineer.

12. All engine belts must be "slacked off" when engine is stopped.

13. If dynamo belts are left tight, notify the man in charge of dynamo floor, or the engineer in charge.

14. If you notice any wires out of place or in trouble, report immediately to the man in charge of dynamos.

15. Do not handle any wires.

16. Smoking is absolutely forbidden.

17. Read all rules as well as those of your department.

ENGINE-ROOM.

1. No one, except employés whose business requires it, is permitted in this room without permission of the chief engineer, or a pass from the office; then only at their own risk.

2. No one must be permitted about the machinery whose business does not require it.

Digitized by Google

3. All are cautioned to use the greatest care when about the engines to avoid accident. Loose or flapping clothing must not be worn, and jumpers or jackets must be worn buttoned.

4. Anything unusual must be reported to the chief engineer at once, or the engineer in charge.

5. In the boiler or engine room, or anywhere else, avoid contact in any manner with wires or lamps.

6. Faulty lamps or other electrical apparatus must be reported at once to the one in charge of dynamo floor.

7. Dynamos or wires on engine floor must not be handled by others than the engineer in charge or the man in charge of dynamo floor, and then only in the manner indicated in the rules for the dynamo department.

8. Should it be necessary, in case of accident, you can instantly stop the alternating current from any machine by throwing the small exciter belt, or by cutting or pulling loose one of the wires from the small exciter which is driven by the machine from which the current should stop. This can be done without danger.

ELECTRIC LIGHTING AT WORCESTER.

RULES FOR INSTALLATION WORK.

The Corporation of Worcester, for the guidance and information of consumers proposing to have their premises fitted for the electric light, have issued the following rules, which embody the principal requirements necessary to ensure safety. The Corporation do not take any responsibility with respect to any installations, nor will they be answerable for any damage which may arise from any defects in them. The Corporation strongly impress on intending consumers the great importance of having the work carried out by competent contractors. Inferior materials and workmanship are the cause of constant accidents and annoyance.

Service.—The Corporation will lay the service line from the main to the meter, and will charge the consumer for the whole thereof, with the exception of the portion of the service line extending from the main to a point 10ft. within the boundary of the consumer's premises, or to the meter, if it be situated within that distance. The portion excepted will be laid without charge to the consumer. The charges to consumers for service lines to supply 16-c.p. 60-watt lamps or their equivalent will be as follows:

	Per yard.
Not exceeding 15 lamps for a distance of 50 yards	3s. 6d.
Do. 15 do. 100 ,, ...	3s. 10d.
Exceeding 15 lamps and not exceeding 20 lamps for a distance of..... 50 yards	3s. 8d.
Do. 20 do. do. 100 ,, ...	4s. 6d.
Do. 20 do. 30 do. 50 ,, ...	4s.
Do. 20 do. 30 do. 100 ,, ...	4s. 8d.
Do. 30 do. 40 do. 50 ,, ...	4s. 6d.
Do. 30 do. 40 do. 100 ,, ...	5s. 4d.
Do. 40 do. 50 do. 50 ,, ...	5s. 3d.
Do. 40 do. 50 do. 100 ,, ...	6s. 10d.
Do. 50 do. 60 do. 50 ,, ...	5s. 8d.
Do. 50 do. 60 do. 100 ,, ...	7s. 4d.
Do. 60 do. 70 do. 50 ,, ...	5s. 8d.
Do. 60 do. 70 do. 100 ,, ...	7s. 4d.
Do. 70 do. 100 do. 50 ,, ...	6s. 10d.
Do. 70 do. 100 do. 100 ,, ...	8s.

The above prices only apply to ordinary cases. Special difficulties or anything which may occasion unusual or unexpected outlay will be charged for extra. The prices include both positive and negative conductors. The main fuse and double-pole switch will be supplied by the Corporation. They will be placed in position by them and sealed. Under no circumstances must the consumer or his contractor in any way interfere with the main fuse and switch, which remain the property of the Corporation. The Corporation reserve the right to settle the positions of the transformer (if any), meter, main fuse, and main switch.

Meter.—The meter and service switch, which will be supplied by and remain the property of the Corporation, will be let to the consumer on hire at the following rents:

For	15	16-c.p.	lamps or	their equivalent	4s. 6d.	per quarter.
,,	30	,,	,,	,,	5s.	,,
,,	60	,,	,,	,,	6s.	,,
,,	120	,,	,,	,,	7s.	,,
,,	180	,,	,,	,,	9s.	,,
,,	240	,,	,,	,,	11s.	,,
,,	300	,,	,,	,,	12s.	,,

General Rules.—The whole of the work in the installation must be of the highest class, and carried out in accordance with the rules of the fire insurance company in whose office the building is insured; or, if not insured, in accordance with the rules of the Institution of Electrical Engineers.

Conductors.—All conductors to be of pure copper, according to Matthiessen's standard of pure copper, and of such sectional area that the current in them shall not exceed 1,000 amperes per square inch, their area to be so proportioned to their length that the fall of pressure between the supply terminals and the farthest lamp shall not, at full load, exceed two volts. All conductors of larger sectional area than No. 14 S.W.G. should be stranded. No conductor to be used of less sectional area than No. 18 S.W.G., except in the case of flexible cords, which may be equal in section to No. 20 S.W.G. All copper wire must be tinned.

Insulation.—All conductors to be highly insulated and mechanically protected by means of tape and braid. Flexible cords to have a waterproof insulation. The insulation resistance of the conductors to be not less than 600 megohms per mile.

Casings.—All conductors to be placed in hard wood casings, except under special circumstances and with the approval of the authorised officer of the Corporation, the casing to be coated both inside and out with varnish or other waterproof composition when placed in damp situations. The covers of all wood casings to be screwed, and not nailed down. Metal staples must under no circumstances be used for fixing conductors; in special cases, however, metal saddles may be employed, subject to approval.

Fittings.—All fittings and electroliers must be insulated at the base. Fittings must be wired with flexible cord. The wiring of gas fittings is expressly prohibited, unless they are efficiently insulated from the gas-pipes, and duly approved.

Switches.—All switches, fuses, etc., to be of fireproof construction, and to have incombustible bases; all switches to have substantial rubbing surfaces, and to have "quick-break" action. No switch to control at one time more than 20 8-c.p. or 10 16-c.p. lamps, or one high candle-power lamp.

Fuses.—All branch circuits to be protected by two single-pole fuses; a single-pole fuse to be fixed at the origin of every flexible cord. All fuses to be of an approved type and easily accessible. Magnetic cut-outs are not to be used in any case, unless previously approved by the authorised officer of the Corporation.

Voltage.—The pressure will be 100 volts at the consumer's terminals, and the lamps installed must be of corresponding voltage.

Arc Lamps.—When it is intended to use arc lamps, the authorised officer of the Corporation must first be consulted in the matter, and the type of lamp, choking coil, etc., must be subject to his approval.

Testing.—The Corporation will not supply current to any installation (1) if there are any temporary wires or fittings; (2) if the whole of the work is not complete and all fittings fixed; (3) if when testing with the full pressure of 100 volts—the insulation resistance should be below the following standard, viz., 75 megohms divided by the number of lamps. Should the installation prove defective when tested by the authorised officer of the Corporation, a fee of 10s. 6d. must be paid before the second and before every subsequent test is made.

Alterations and Additions.—No alterations must be made, or any additional lamps installed, until a notice of seven days in writing has been given to the Corporation. Failure of such notice may render it necessary for the entire supply to be cut off.

Leakage.—In the event of the insulation resistance of an installation falling below 5,000 ohms, after a supply has been turned on, the whole of the installation will be cut off until the fault has been put right. Any expenses the Corporation are put to in finding such fault must be repaid by the consumer. The Corporation reserve the right to test any installation from time to time.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Hapton (Lancs.).—Tenders are invited for lighting with electric light the village of Hapton and so much of the township of Hapton as the lighting inspectors may think necessary. Full particulars may be had of the work required to be done by applying to Mr. Henry Cunliffe, chairman of the Lighting Inspectors, Post Office, Hapton, to whom tenders are to be delivered by 27th inst.

Sunderland.—The Corporation require tenders for wiring the Town Hall, including the supply and fixing of all cables, casings, switch and fuse boards, lamps, etc. Copy of specification, etc., may be obtained at the office of the borough electrical engineer on the deposit of £1. 1s. Further particulars are given in our advertisement columns. Tenders must be delivered at the office of Mr. Fras. M. Bowey, town clerk, not later than November 8.

Halifax.—Tenders are invited for the covering of the boilers and steam-pipes for the new electric light works, Foundry-street, Halifax (asbestos or fossil meal), for the Electric Lighting Committee. Particulars may be obtained on application at the Electrical Engineer's Office, Foundry-street. Tenders, endorsed "Tender for Pipe Covering," must be sent to Mr. Keighley Walton, town clerk, before 10 a.m. on 22nd inst. The tender of any person paying less than the minimum standard rate of wages, and who does not observe the hours and conditions of labour generally recognised in the district, will not be accepted.

London, E.C.—Tenders will be received until noon on Wednesday, 31st inst. (*a*) for supply of red fir telegraph poles, to be

Digitized by Google

delivered in London, King's Lynn, or Sutton Bridge, and at Northumberland Dock (River Tyne), West Hartlepool, Hull, or Grimsby; and (*b*) for creosoting the poles with 10lb. or 12lb. of creosote to the cubic foot as may be directed. The poles to be felled between November 1, 1894, and February 28, 1895, and to be delivered during the following summer at the port at which the creosoting is to be performed. Butt sections from not less than three poles, to show the quality of timber offered, must precede or accompany the tender of any person who has not already supplied the Postmaster-General with poles. The Postmaster-General does not bind himself to accept the lowest or any tender. Forms of tender, containing all particulars, may be obtained on application to Chas. E. Stuart, controller of stores, Telegraph-street, E.C.

London, W.C.—Mr. John Annan, manager for Mr. Samuel Wheeler, "Official Receiver in Companies' Liquidation," acting as liquidator of J. W. Hobbs and Co., Limited, is prepared to receive tenders for the supply and erection on foundations, etc., provided by contractor in the hotel in course of completion on the Salisbury Estate, Victoria-embankment, of the following plant: (Section A) boiler-house plant—boilers and fittings, feed heaters, electric feed pump, injector, water-tank, steam, exhaust, feed, blow-off, and sundry pipes and valves, etc.; (B) engine-house plant—oil-tank, steam dynamos, oil filter, workshop fittings, ventilating fan, etc.; (C) switchboard, instruments, and meters. Tenderers are at liberty to tender for any section or sections, or for the whole of the sections, but not for part of a section. The ground plan of the buildings, and the specification, with terms and conditions of tender and contract, may be obtained at the offices of Mr. R. Hammond, the consulting engineer, Ormond House, Great Trinity-lane, London, E C, on payment of £2. 2s. Tenders to be addressed to Mr. J. Annan, 2, New-court, Carey-street, Lincoln's-inn, London, W.C., by 26th inst.

RESULTS OF TENDERS.

Cheltenham.—The tender has been accepted of Messrs. Humpidge, Holborow, and Co., Stroud, at £82, for the construction and erection of a seven-ton hand-power overhead travelling crane at the municipal electric light station.

Stafford.—For supplying conductors on the three-wire system for electric lighting, for the Town Council. Dr. Hopkinson, consulting electrician:—Siemens Bros. and Co., £1,290 (accepted) For overflow mains and exhaust pipes for engines: W. G. Bagnall and Co., £75 (accepted).

London, E.C.—The proprietors of the City Terminus Hotel, Cannon-street, E.C., have accepted the tender of Messrs. Robey and Co., of Lincoln, for the supply of a locomotive type boiler, together with a complete system of duplicate main steam-piping, etc., the whole to be supplied and erected to the specification and plans of their engineer, Mr. W. Durtnall, A.M.I.E.E.

London.—At Tuesday's meeting of the London County Council the Fire Brigade Committee reported as follows: "We reported on July 24 that, as the contract with Messrs. H. Binko and Co. for the maintenance of the electric bells belonging to the brigade would expire early in August, we propose to invite tenders for the maintenance for a further period, and that we had authorised the chief engineer to arrange for the work to be done by workmen directly employed by the Council, until the new contract should be entered into, and the Council approved our action. We have now to report that the cost incurred in maintaining the bells, including the substitution of new batteries for defective ones, and the execution of repairs to the wires and apparatus, has been about £95. Six firms were invited to submit alternative tenders for the maintenance of the bells for one or three years, but only five responded, their prices being as follows:

	For one year.	For three years.
A. W. Jackson	£325	£285 0 0
J. Sax and Co., Limited	325	303 6 8
Strode and Co.	330	330 0 0
J. D. Andrews and Co.	400	350 0 0
Nicholson and Lyle	1,050	1,000 0 0

The result of enquiries made by the solicitor with regard to the lowest tenderer appears satisfactory, and we recommend that the tender of Mr. A. W. Jackson to maintain for three years at the rate of £285 a year the electric bells belonging to the brigade be accepted." This was agreed to, with the proviso that the contract should be for one year only.

BUSINESS NOTES.

Alderley Edge.—A provisional order is to be applied for by the Local Board.

Reading.—An extension in the mains is being made by the local electric lighting company.

Bray.—The Town Commissioners have resolved to promote a Bill for electric lighting purposes.

Bolton.—The opening of the municipal central station has been postponed from the 24th to the 31st inst.

Mill-Lighting.—It is stated that the electric light is to be introduced into several Dundee jute mills.

Lowestoft.—Mr. F. H. Medhurst is to meet the Town Council to discuss the question of electric lighting.

Basingstoke.—The Town Council have referred Mr. Hammond's report to the Electric Lighting Committee.

Douglas (Isle of Man).—It is suggested that the local authority should introduce a supply of the electric light.

Keighley.—The Town Council have referred back to committee the question of applying for a provisional order.

Windsor.—Alderman Dyson has resigned his membership of the Electric Lighting Committee of the Town Council.

Sunderland.—The Town Hall Committee have made further arrangements for lighting the building by electricity.

St. Pancras.—The demand for current has reached such an extent that a second central station is now in course of erection.

Barrow.—The Town Council have declined to authorise the Selection Committee to consider the question of electric lighting.

Montrose.—The Town Council have agreed to support the application of the Scottish House-to-House Company for a provisional order.

Fareham.—The Local Board have received from the Board of Trade permission to take over the undertaking of the local electric lighting company.

Darlington.—The Town Council do not seem disposed to carry out their electric lighting powers until they are assured that there is a demand for the light.

Westminster Electric Supply Corporation.—This Company have called a meeting of shareholders for the purpose of increasing the capital from £300,000 to £400,000.

Middlesbrough.—The books in the free library having suffered from the use of gas on the premises, the building is to have the electric light installed by Messrs. Baker Bros.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ending 14th inst. amounted to £906, as compared with £582 in the corresponding week of last year.

London, E.C.—The new Post Office building in St. Martin's-le-Grand is approaching completion. The whole of the building will be lighted by electricity, and there will be no gas fittings whatever.

Southwark.—The premises of Messrs. Burton, Baker, and Co., 110 and 112, Southwark-street, S.E, are being installed with the electric light by Messrs. W. J. Wolfe and Co., 11, Queen Victoria-street, E.C.

Coventry.—The Town Council have ordered that Mr. G. S. Ram be appointed clerk of works to superintend the engineering portion of the contract for the equipment of the electric lighting station at a salary of £4 a week.

Hove.—The Town Hall Committee have held a meeting for the purpose of testing the efficiency of the electric light at the Town Hall, and the result was regarded by the gentlemen present as entirely satisfactory.

Scarborough.—The annual report of the Scarborough Cliff Bridge Company, Limited, shows an increase in the expenditure of £493. This is partly accounted for by the installation of the electric light in the theatre.

Leeds.—The temporary electric lighting of the grounds and picture gallery at Temple Newsam during the visit of the Duke and Duchess of York was placed in the hands of Messrs. Maunsell Mercier and Co., of Manchester.

Llanberis Water and Gas Company, Limited.—This Company has been registered with a capital of £5,000 to establish and carry on works for the supply of water, gas, electricity, etc., to the parish of Llanberis, co. Carnarvon.

Farnworth.—The General Purposes Committee of the Local Board will shortly consider the question of convening a meeting of the Electric Lighting Committee for the purpose of discussing an application for a provisional order.

St. James's and Pall Mall Electric Light Company, Limited. This Company announces that the electric current sold during the quarter ended September 29 amounted in value to £6,935, as against £4,820 for the corresponding period of 1893.

Birmingham.—On Tuesday Colonel W. M. Ducat, R.E., an inspector of the Local Government Board, held an enquiry into an application of the Corporation to borrow various sums of money, including £1,000, for lighting the market hall by electricity.

Stalybridge Foundry Company, Limited.—This Company has been registered with a capital of £15,000 to acquire the Britannia Foundry, at Cockbrook, Ashton-under-Lyne, and to carry on business as iron, steel, and brass founders, mechanical and electrical engineers, etc.

West India and Panama Telegraph Company.—For the first half of the current year the directors recommend a dividend of 6d. per share. For the two weeks ended October 15 the receipts show an increase of £224 as compared with the corresponding period of last year.

Appointment Vacant.—The Corporation of Cardiff require an electrical engineer to take charge of their electricity works. Applications are to be addressed to Mr. J. L. Wheatley, town clerk, Town Hall, Cardiff, not later than October 22. The salary offered is £3 per week.

Hastings.—The Board of Guardians have ordered a number of bills to be paid, including one for 11s. 9d. for electric light in the Wellington-square offices. Several members expressed their surprise at the smallness of the bill, but the clerk explained that during the summer quarter the light was not used very much.

Sandycroft.—The Sandycroft Foundry and Engine Works Company are at present engaged in laying an electric line of railway from their works to the side of the London and North-Western Railway. The line is a short one, and the company are sanguine

Digitized by Google

that they can do the running of their trucks cheaper by electricity than by steam.

Technical Association of London, Limited.—This Company has been registered, with a capital of £100,000 in £100 shares, to acquire, by purchase or otherwise, any patents, licenses, inventions, concessions, grants, etc., and to develop and turn to account the same in such manner as the Company may deem expedient.

City and South London Railway.—The receipts of the Company for the week ended October 14 were £921, against £851 for the corresponding week of 1893, or an increase of £70. The total receipts for the current period of the present half-year amount to £12,931, as against £12,146 in the corresponding period of 1893, an increase of £785.

Fulham.—The Town Hall Committee of the Vestry have discovered now that the work of decorating the Town Hall is being proceeded with, that gas is likely to spoil the decorations. The hall is not wired, but the committee have instructed the surveyor to obtain information and report as to the probable cost of installing the electric light.

Dover.—The preparations for introducing the electric light, although not progressing so rapidly as was expected, are now fast approaching completion. The mains are all in; the station at Park-street is practically completed, the main cables are being drawn into the pipes along the streets, and all the transformer sub-stations are nearly finished. The completion of the engines seems now to be all that is needed.

Liverpool.—The monthly meeting of the Markets Committee was held on Tuesday. Mr. Walker stated that the markets were the pink of perfection, but urged that they should as soon as possible light them by electricity. Mr. Dean agreed to the necessity for the suggested improvement in lighting. Mr. E. Paull, the chairman, also thought it would be necessary soon to light the markets with electricity.

Richmond.—The Electric Lighting Committee of the Town Council reported that the plan deposited by the company shows a proposal to carry the main as far only as the Wick, and recommended the Council to call upon the company to undertake to continue the main to the full extent of the added area—viz., to opposite the Star and Garter Hotel—when required to do so by the committee. This was agreed to.

The Electric Railway to Snowdon.—The electric railway to Snowdon, which has so much been spoken of, is now beginning to take shape. A company has been registered, under the name of the Hotels and Railway Company of North Wales, Limited, with a capital of £6,000 in 60 shares of £10 each, to construct a railway from Llanberis, Carnarvon, to a point near the summit of Snowdon, and to erect and carry on an hotel at or near the summit.

Market Harborough —An electric light and power plant is to be installed by Messrs. Lea, Sons, and Co. in Messrs. Lymington's large corset factory. There will be required two steam dynamos, one of 50 b.h.p. for lighting (700-800 lamps), and one of 80 b.h.p. for transmission of power by means of eight electric motors placed in different portions of the factory. The plans were drawn out by Mr. Arthur H. Lea, M.I.M.E., and the work will be done under his personal supervision.

London, E.C.—Messrs. W. J. Wolfe and Co., 11, Queen Victoria-street, E.C., and 7, Folkestone-road, Dover, are at present carrying out electric light installations in the City for Messrs. Perrin and Co., Crosby-square, Bishopsgate-street; Messrs. J. F. Duboc; and the Imperial Contract Corporation, Limited, at their offices, Wool-exchange, Coleman-street. Messrs. Marshall, Girling, and Co., and Mr. Herbert Cubison, are also having their offices fitted at West India House, Leadenhall-street.

Walsall.—The Gas Committee of the Town Council have reported that the Local Government Board having refused to approve of the arrangement proposed, whereby the sum of £2,250 was to be paid to the credit of the gas undertaking out of the proposed loan for electric lighting, for the site of the electric generating station at Wolverhampton-street Gasworks, the committee had approved of the sum of £90 per annum being charged the electric lighting undertaking as rent for the site of the station.

Radcliffe.—Mr. S. Walker, the chairman of the Local Board, at a meeting of that body gave an account of his impressions at the recent Sanitary Congress held in Liverpool, and stated that among the questions which greatly impressed him were those referring to sewage and electric lighting. He had been on both committees, and, as most of them knew, he had urged that if possible they should have the two works close together on one plot of land, so that they might be worked one to the advantage of the other.

Isle of Man Electric Tramway Company.—The directors of this Company have issued a circular in which they state that, having carefully considered the profits for the past season, and having consulted with the auditors, they have, after providing a large sum for the reserve and renewal fund, and making provision for further dividends at the end of the year, decided to pay an interim dividend at the rate of 6 per cent. per annum on the preference and of 7½ per cent. on the ordinary shares for the six months ending October 31.

Ealing.—The Local Board have referred to the Electric Lighting Committee a communication from the Free Library Committee stating that the latter would be prepared to use the electric light on the library premises at an annual sum to be agreed upon. A memorial from residents on the north side of the railway (The Parade, Woodville-road, etc.), asking that the electric light mains might be carried over the Feathers Bridge and into the northern part of the district, was referred to the Electric Lighting Committee.

St. Martin-in-the-Fields.—A copy of the annual report by Mr. Chas. Mason, A.M.I.C.E., A.R.I.B.A., surveyor to the Vestry of St. Martin-in-the-Fields, Charing Cross, W.C., has reached us for the year 1893-94. With regard to electric lighting, Mr. Mason says that several reports have been submitted by him upon the desirability of lighting the streets of the parish by means of electricity. The question has, however, been postponed, as it is found, he states, that the cost of lighting with electricity will exceed the amount now paid for gas.

Carlisle.—The Town Council have decided that the application of the County of London and Brush Provincial Electric Lighting Company, Limited, for a provisional order for the supply of electricity within the city of Carlisle be opposed, and that the Council be recommended to make application for a provisional order in the ensuing session of Parliament, for the purpose of authorising the Corporation to supply electrical energy for public and private purposes within the city of Carlisle, and to acquire all proper and necessary powers in connection therewith.

Dublin.—A deputation of the residents of Moore-street waited upon the Electric Light Committee of the Dublin Corporation on Thursday of last week in reference to the decision arrived at recently of the inhabitants to advocate the lighting of the place by electricity. The deputation was received favourably by the committee. The borough surveyor, Mr. Harty, also attended. It is understood that the work of laying down the mains will begin soon, and the deputation were in a position to state that a number of the residents of the district was prepared to take the light.

Windermere.—The electric supply company have written asking whether the Local Board favoured their intention of applying for a provisional order. The Clerk said it would be better for the Board to wait until the provisional order was actually before them. He had sent to the Board of Trade for a copy of such provisional order, but found that it was not much of a guide, the schedules, of course, not being filled up. He thought that the interests of the Board would be very well protected. Mr. Irving asked if the provisional order gave a monopoly to the company to supply the place. The Clerk: Practically so.

Taunton.—The Electric Light Committee of the Town Council have reported that they had a letter from Dr. Fleming offering to act as consulting engineer for the year ending September 1, 1895, for a fee of 25 guineas, with a fee of 10 guineas per visit to Taunton and travelling expenses. The committee recommended that his offer be accepted. The committee also recommend that Mr. A. J. Howard (whose pupilage expired on the 1st inst.) be retained as an assistant electrician at a salary of £40 a year. The report was adopted. The borough surveyor was instructed to arrange for placing temporary electric lamps in Mill-lane and Steven's-court, North-street.

Warminster.—A special committee of the Local Board have reported that they had received tenders for dynamo, cable, etc., required in the electric light installation, and the expenditure would not exceed the amount previously estimated—viz., £234. In the course of the discussion it was stated that six additional electric lamps were proposed to be erected for the illumination of the principal streets, and in the event of the experiment proving successful other parts of the town would probably be lighted by electricity. The clerk was directed to apply to the Local Government Board for their sanction to a loan to carry out the installation.

Newport (Mon.).—The handsome columns selected by the Electric Lighting Committee of the Newport Corporation for the arc lights are being rapidly placed in position along Commercial-road and Commercial-street. The columns are placed alternately on each side of the roadway, and judging from the distance they are apart would appear to provide adequately for the lighting of the thoroughfares. Some disappointment is felt in some of the suburbs at the conduits not being laid as extensively as was thought probable, and householders who have been waiting for the electric light have in consequence resorted to latest improvements in gas and oil for their dwellings.

Burslem.—During the visit of the Princess Louise to Burslem temporary electric lighting was carried out by Messrs. Crompton and Co The electric illuminations of the town consisted of six arc lamps of about 3 000 c.p. each. One was placed by the Manchester and Liverpool Bank, another by the Town Hall, another by the Conservative Club, another at the Wedgwood Institute, another on Swan Bank, and the sixth in St. John's-square. The whole of the plant was fixed by Messrs. Crompton, and the lamps lent by the Sneyd Colliery Company, Limited, as also about 100 incandescent lights for four of the triumphal arches—viz., the one at the top of Newcastle-street, that at the top of Nile-street, that at the top of Moorland road (Market-square end), and the one in Waterloo-road. Messrs. Crompton lent the dynamo and the conductors, etc., for the lighting, and the motive power was supplied from the steam-roller situate in Brickhouse-lane.

Venezuela Telephone and Electrical Appliances Company, Limited.—The accounts show a profit of £7,413. 5s. 11d., to which is added the balance of £1,558. 9s. 7d. standing to profit and loss account. After providing the interest on the first and second mortgage debentures, amounting to £4,393. 8s. 6d., the directors have written off the sum of £1,711. 15s. 3d. from the discount and expenses on debenture issues. This leaves a balance of £2,866. 11s. 9d., out of which the directors recommend that a dividend on the Company's share capital be declared for the year ended June 30, 1894, at the sate of 4 per cent. per annum, which will absorb

Digitized by Google

£2,800, and that the balance of £66. 11s. 9d. be carried forward. The Company's property having been fully maintained, as set forth by the general manager's certificate at the end of the balance-sheet, the Board does not consider it necessary at the present time to make any allowance for depreciation of plant.

Electric Traction at Dublin.—The conversion of the Dublin Southern District Tramway Company's lines, stretching over the entire distance from Dublin to Dalkey—eight miles along some of the most beautiful scenery in Wicklow—will soon be actually begun; in point of fact the material and plant is being ordered, and the contractor is preparing to break ground, so that the entire service may be operated by electricity before next summer season fairly commences. Water-tube boilers are to be used in the generating station, two 300-h.p. Babcock boilers being first installed; whilst the engines—of the compound condensing horizontal type, coupled to the dynamos by belting—will be three in number, of 150 h.p. each. When completed this line ought to prove one of the best and most profitable in the whole country, even more so than the Isle of Man electric tramway, as it will not be dependent solely upon a summer traffic, great as that may be.

London, E.—The Bow Vestry have considered the proposals of the Poplar District Board to instal electric light in the district. The Poplar Board are circularising the inhabitants in order to ascertain if there is a desire for a supply of electricity. The price proposed to be charged is 6d. per Board of Trade unit for light, and 4d. for power. Meters would be supplied by the District Board at 10 per cent. on the cost, the connection with the mains and the inside fittings being supplied at the expense of the consumer. As far, however, as Bow is herein concerned, the proposal has been left over until the next election. The Whitechapel District Board have decided to inform the secretary to the City of London Electric Lighting Company that the site they offer to the Board for a power station will not be required, as in their present destructor premises excellent accommodation is afforded. By the utilisation of the waste heat in the destructor premises, the Whitechapel governors hope to justify their provision of electric light, which they can supply at 5d. per unit, as against 8d. charged by the City company.

Yarmouth.—The Town Council have decided to light the Fish Wharf by electricity. The Council was recommended to light the Town Hall electrically. The surveyor estimated the lowest possible cost at £300. After November 1, 134 gas lamps will not be required in the town, and necessary notices were ordered to be served on the gas company, saving an annual expenditure of £500 The Elder Brethren of the Trinity House recommended the screening of two of the electric lights near the Sailors' Home. The screens, they stated, would not interfere with the light delivered on the parade and beach. The number of applications received for the supply of current to October 2 was 12 for 700 lights, including the School of Art; but not the Fish Wharf, Town Hall, police station, and free library, which would require 700 more lights. The plant is equal to 4,500 lamps in use, which would allow for installing about 6,000 lamps. It was decided to engage a man at 32s. per week for making connections with private consumers, and tools for the same purpose at a cost of £15 were ordered. The report was adopted.

Wolverhampton.—Councillor Rhodes has asked at a meeting of the Town Council whether it was proposed to take the electric light below Chapel Ash. Councillor Cousins asked what time they might expect that the lighting arrangements would be completed. Alderman Gibbons wished to know why the circuit had not been taken below St. Mark's Church. Councillor Weaver said it was decided some time ago that St. Mark's Church clock should be lit up. Considering that some 20,000 persons looked to that clock for the time, it ought. he thought, to be illuminated. The junction of Chapel Ash and Tettenhall-road, Compton-road, and Merridale-road was one of the darkest spots in the town, and he was of opinion that the electric light ought, if possible, to be taken there. The Mayor said it was his wish to see as large an area as possible of Wolverhampton lit with the electric light, and at the earliest possible moment. He was in hopes that it would have been installed by this time All the contractors contracted to complete their work before September 18 last, but owing to the carpenters' strike and other causes, it had got behind. It would, however, be completed in a few weeks.

Birmingham Central Tramways.—An extraordinary general meeting of shareholders of the Birmingham Central Tramways Company, Limited, has been called for the 24th inst. to reconsider the question of the reduction of capital recommended by the directors. Messrs. Neale, Round, Booth, and Mantle, directors of the Company, in a circular asking for proxies, say: "As long as the capital remains at the excessive amount at which it stands, a much larger sum must be set apart for reserve than will be necessary if the capital is reduced. It is notorious that a part of it is lost, and neither the shares nor the dividend will ever attain the steadiness which they ought to do until the reduction is effected. We, as directors, the auditors you have yourselves appointed, and the principal shareholders are unanimous that it is necessary for the future prosperity of the Company. It is for you to consider whether you will allow the personal feeling of one or two members of the Shareholders' Association against the chairman, who has rendered such great services, to wreck the Company and destroy the value of your property. If you are opposed to the latter course, please send us your proxy at once, and give us any other support in your power."

Brazilian Submarine Telegraph Company, Limited.—The report of this Company for the half-year ending June 30 states that the revenue amounted to £94,679, and the working expenses to £20,269. After providing £12,880 for debenture interest and sinking funds, and £1,736 for income tax, there remains a balance of £59,794, to which is to be added £2,207 brought forward from December, making a total of £62,001. A quarterly interim dividend, amounting to £19,500, has been paid, and £15,000 transferred to the reserve fund. The directors now recommend the declaration of a final dividend of 3s. per share, making, with the interim dividends, a total distribution of 6 per cent. for the year, and also the payment of a bonus of 1s. per share, both free of income tax, which together will amount to £26,000, leaving a balance of £1 501 to be carried forward. On July 31 the sum of £18,700 was transferred to pay off 187 bonds, the balance of the 1884 issue. The receipts include £1,500, the dividend to December 31 on the Company's shares in the African Direct Telegraph Company. The directors report that Sir Henry D. Gooch has resigned his seat at the Board, and that it is not considered necessary to fill the seat at present. The various sections of the line are in good working order.

Dewsbury.—A quarterly meeting of the governors of the Dewsbury and District Technical School was held on Tuesday evening, the president, Mr. S. J. Chadwick, in the chair. The president brought forward the question of introducing the electric light into the school, and said the attendance of pupils was now so large that the air in the several classrooms became bad, this being aided by the foul air arising from the combustion of gas. It would be a benefit to have each classroom lighted by electricity, but the question was, could they afford it in the present state of their finances? Mr. Hobkirk observed that the light would be very beneficial and Messrs. Richards and Thompson spoke to the same effect. Ultimately it was unanimously resolved on the motion of Mr. Hobkirk, seconded by Alderman Richards, that the Corporation should be asked to give an estimate of the expense of putting in the necessary fittings, and the annual cost of supplying electricity according to a plan of lighting to be sent in. It was remarked that if the Infirmary Board thought of introducing the new light into the institution the present application might lead them to enquire now, and that there was reason for believing that the trustees of Springfield Chapel intended to have an installation.

Oxford.—Good progress has been made in connection with the electric light in Oxford during the past year It is a little more than two years since the electric light station was opened, and during this time the business of the company has increased in a very satisfactory manner. In October, 1892, there were 2,000 lamps connected to the mains; in October, 1893, this number had grown to 7,000; at the present time the number is 11,000. If this rate of progress is maintained the company will have to considerably augment their generating plant at Osney. It has already been found necessary to put an additional generator in the sub-station at St. John's College, and a site has been found for a new sub-station in North Oxford. Amongst important installations which have been carried out this year under the management of Mr. Hardie McLean, M.I.C.E, are those in Trinity, Oriel, Exeter, Worcester, and Wadham Colleges, Magdalen College School, the house of Mr. Daniels, bursar of Worcester, the Turkish baths, and the Clarendon Hotel, in addition to numerous shops and private houses. During the year the company's mains have been laid in St. Aldate's, Beaumont-street, King Edward-street to Oriel College, and over Magdalen Bridge. The extension to North Oxford, now in progress, should be an important feature in the history of this electric lighting, taking in, as it does, the principal residential parts of the city.

Woking.—The Sanitary and Lighting Committee of the Local Board in their report referred to an interview they had had with Messrs. New and Mayne with respect to the diameter of the base of the standard, and also as to their difference in height and shape from the original standard selected by the committee. The clerk read a letter from Messrs New and Mayne, who regretted that owing to a misunderstanding the lamp-posts for the street lighting had been made lighter than those shown on the drawing. If the Board would grant them an extension of time until November 6 to carry out their contract they would at once put in hand new bases and columns. Mr. Storey said that the difference in the size of the standards was very considerable, and he should think the weight would be reduced by about 35 per cent. The Sanitary Committee arranged, subject to the Board's consent, to grant the extension asked. He believed that the contractors acted in perfectly good faith, but they made a very serious mistake, which they recognised. Ths delay in the lighting would of course be a great delay to the contractors themselves. Mr. Butt asked if the contractors made any suggestion to the committee that the Board should accept the columns at a reduction? Mr. Storey: No, nor do the committee, because they regarded the columns erected as most trumpery and a disgrace to the town. On the motion of Mr. Harris, seconded by Mr. Harding, it was agreed to grant the extension.

Crystal Palace.—The Crystal Palace District Electric Supply Company are issuing prior lien bonds bearing 4½ per cent. interest, and secured as a first charge on the entire property of their undertaking, on which it is understood that upwards of £70,000 has already been expended. According to the prospectus of these bonds, the business of the company has progressed in a most satisfactory way, the number of lamps equal to 8 c.p. installed on July 1, 1893, being 2,850, whilst at the end of September they had reached a total of 6,180. Amongst the recent customers of the company is the north tower at the Crystal Palace, the lifts for which are worked by the aid of electric motors, and the tower illuminated with current supplied by the company. It is intended to extend the company's mains immediately to

Digitized by Google

Forest Hill, in order to meet a demand by the principal business establishments in that locality. The Crystal Palace District Electric Supply Company, Limited, were summoned on Tuesday at the instance of the Lewisham District Board of Works for causing an effluvium to issue from their works at Springfield, Wells-road, Sydenham, contrary to the provisions of the Public Health Act, 1891. Mr. Young appeared for the Board to prosecute, and Mr. W. H. Nash was counsel for the defence. A number of witnesses were called, who stated that from time to time offensive vapours had been proceeding from a shaft at the company's works. On the other hand, it was contended that the smell did not come from the company's premises, and that if there was any smell it was from the burning of refuse. Mr. Laws, a solicitor, said that since the issue of the summons he had noticed no smell of which he could complain. The summons had been standing over since August. Mr. Young said that, in view of the improvement, he was willing to agree to an adjournment *sine die*, and to this Mr. Nash consented, on the distinct understanding that he made no admissions of any kind, and the company did not admit that there was any nuisance. Mr. Offor, the managing director of the company, said that there could not have been any improvement, because no alteration of any kind had been made. The summons was then adjourned *sine die*.

Portsmouth.—The Electric Lighting Committee, at a meeting of the Portsmouth Town Council, have submitted a report dealing with their receipts and expenditure since the starting of the works. The sum authorised by the Council for the carrying out of the installation was £60,000. The estimate was made up to £56,385 for land, engines, dynamos, cables, etc., and £3,615 for capital and contingencies. The Local Government Board sanctioned the former sum, but struck out the latter, with the intimation that it could be had from time to time as required for those purposes. Since then two sums of £550 and £1,265 had been sanctioned for extensions in Russell-street, South-parade, Clifton-road, and the drill hall, bringing the full amount up to £58,200, besides which the committee had now joined up 160 house services, at an average cost of £10 per house, which sum it would now be necessary to borrow. They, therefore, recommended that application be now made to the Local Government Board for permission to borrow £1,800, the remaining balance of the £60,000, which would leave a small amount in hand for immediate necessities. In moving the adoption of the report, Alderman Ellis said there was every probability of the committee paying its way on the first year's working. So far as the public lighting was concerned, the cost was £1,800, which was £200 less than the figures originally suggested by Dr. Garnett, and accepted by the Council. He had put down £5,000 for private lighting, and though that was only an estimate, he thought he could show it was a very fair one. They had taken the average earnings in the towns in the United Kingdom having the electric light. The average was 19s. 11d. per lamp per annum. In Portsmouth most of their consumers were shopkeepers, and he thought the committee was justified in putting down 20. During the first (the summer) quarter—and it should be remembered that it was rather less than a quarter, because many persons were not connected until after the quarter had started—they had earned £1,000. The expenses were more difficult to work out. In concluding, Alderman Ellis said he had been assured by competent authorities that their light was better than that of the City of London Mr. Couzens seconded. In answer to questions, Alderman Ellis said it was not intended to light the esplanade lamps during the five winter months, but the question as to whether it should be lighted up on Sundays had not been decided. The report was adopted.

Kensington.—The Select Electric Lighting Committee of the Vestry submitted the following report: "That the committee have had before them, pursuant to the reference by Vestry of June 13, 1894, a letter from the Notting Hill Electric Lighting Company, notifying, in pursuance of the provisions of the Electric Lighting Act, 1882, the intention of the company to apply for a provisional order empowering them to supply electricity in the area recently abandoned by the House-to-House Electric Light Supply Company in the northern part of the parish, and specifying the compulsory streets to be scheduled in the application; and also (in pursuance of the reference by the Vestry of July 4, 1894) the notice under the Electric Lighting Acts from Messrs. Jordan and Son, on behalf of the Commercial Electricity Supply Company, of the intention of the company to apply for a provisional order empowering them to supply electricity in various parishes, districts, and extra parochial places in the Metropolis, including the whole or some part of the parish of St. Mary Abbotts, Kensington, and the committee recommended that the vestry clerk be directed to forward a communication to each of the companies named, intimating that the Vestry will be prepared to further consider their respective applications as soon as the draft provisional orders are before them. That the committee have (in pursuance of the reference by the Vestry of September 26, 1894) had before them the letter from the Board of Trade forwarding, for any observations which the Vestry desire to offer thereon, copy of regulations and conditions for securing the safety of the public and for ensuring a proper and sufficient supply of electrical energy in the House to-House Electric Light Supply Company's area, together with an amended description of the system by means of which energy is to be supplied. Your committee have deemed it expedient, before arriving at any decision as regards the amended description of the system proposed to be sanctioned by the Board of Trade, to obtain further information on certain points from the House-to-House Electric Light Supply Company, and they have accordingly directed the vestry clerk to apply to the company for the required information, and also to write to the Board of Trade asking that the Board will await the observations of the Vestry before approving the said amended description of system of supply." Mr. Brayè moved that the matter be referred to the Electric Lighting Committee. Mr. Holmes asked the Vestry to remember that they represented a district of some repute, and advised them not to act in a dog-in-the-manger style. The matter was then referred to committee.

Tonbridge.—The clerk to the Local Board presented the following statement in reference to a notice received from the Holloway Electricity Supply Company, Limited, and the question of obtaining a provisional order: "The Holloway Electricity Supply Company, Limited, are applying to the Board of Trade for a provisional order authorising them to supply electricity for public and private purposes within the district of the Tonbridge Local Board. If the application is granted, the company will be in a position to control the lighting of the district with electricity for 42 years from the date of the provisional order, and may make contracts with any other company or firm for the supply of electricity. Should the Board oppose the application, they will have to show cause why the provisional order should not be granted, and the practice of the Board of Trade is now to grant these applications unless the local authority are themselves prepared to apply for the powers. If a provisional order were obtained by the Board, they would be allowed a nominal period of two years in which to commence the work, but if not begun in that time no steps would be taken by the Board of Trade to rescind the order unless an application (involving a considerable outlay) were made by some person who would have to show that the requirements of the district were being neglected by the Board. Having obtained the order, the Board would be in a position to contract with a company or firm to supply with electricity and to make such terms as they thought fit The cost of a provisional order, including the necessary printing and a fee of £50 to be paid to the Board of Trade, would probably be about £150." The Chairman said that if the Board went for these powers it would be a question whether they could not make a profit by farming them out to some company. He thought there would be no difficulty in getting their money back again. Mr. Race remarked that electric lighting was making great strides, and the Board should not neglect this opportunity, or they might hereafter regret it. Mr. Jones held that the Board ought to have this power in their hands the same as they ought to have had the power of supplying gas and water. He considered that the few should suffer for the many instead of the many suffering for the few, as was now the case. He did not happen to have any vested interest in the supply of gas and water, but he had seen by the papers that at Ealing the town refuse and sewage sludge were used in the generation of electricity, and if that could only be done in Tonbridge it would be a glorious thing, for then they would not have Mr. Hollomby complaining of the destruction of fish in the river, or resident gentlemen of the smells arising from the deposit of sewage on the farm land. Why, the place would become a little heaven below, and all for the sake of £150. By all means let them have electricity at once. After some further discussion, it was resolved to apply for a provisional order.

Cardiff.—A meeting of the Cardiff Lighting and Electrical Committee was held at the Town Hall on Tuesday morning, under the presidency of Alderman Carey. The Mayor asked when the electric lighting works would be formally opened. It was announced that the current would be turned on on Monday night, and a large number of people assembled in the streets. The Chairman said he was not in a position to answer the Mayor, but there was a report from Mr. Massey, which he would ask the clerk to read. Mr. W. H. Massey reported to the committee that Messrs. Siemens were busy testing their dynamos, rectifiers, and lamps, and, judging from the preliminary runs, everything seemed to answer very well. As soon as the contractors had finished their tests the works might be started and formally opened. Mr. Massey, however, called the committee's serious attention to the fact that the number of incandescent lamps wired in Cardiff (as distinct from mere applications for the supply of current) was too small to warrant the committee using the machinery at the station regularly night and day. The present staff was quite sufficient to run the street-lighting and to supply current during the evening to a few shops, but it would be well, in anticipation of heavier work being required during the coming winter, to advertise for a practical foreman. The Mayor said they were sustaining a heavy loss through not having the light ready. Many persons had been prepared for two or three months to take the new illuminant, but, in consequence of the delay in supplying it, they were putting in new burners for gas. He was wrongly reported when he was made to say that there was apathy among the townspeople in this matter. The apathy was on the part of that committee in not bringing the light to perfection. He would like to know why penalties had not been enforced in the case of contracts which had not been completed in the specified time. The borough engineer, Mr. Harpur, said the Corporation were not losing money. If they turned the light on now they would lose £700 to £1,000 a year, because of the small number of lamps which had been wired for private consumption. At the present time there were not more than 500 wired, and they wanted 4,000 to 5,000 to make the electric light pay. Mr. Gerhold: Are the streets not to be lit with electricity until 4,000 to 5,000 private lamps are wired? The Borough Engineer: I am speaking of running night and day, to which Mr. Massey refers. Mr. Good: If you have private consumers you must run night and day. The Chairman thought the Mayor was correctly reported when he said there was apathy

Digitized by Google

among the townspeople. There certainly was apathy compared with other towns where electric light had been introduced. They had requested the inhabitants to go on wiring, and the committee would be ready as soon as they were. He believed they would be able to run the light in a fortnight. The lighting of the streets would mean a loss of about £500 per annum, and unless the Corporation were assisted by private consumers the loss would be much heavier. Alderman Jacobs: Everything is going on satisfactorily, and it is no use turning on the light until the proper tests are made. After some further conversation, the subject dropped.

PROVISIONAL PATENTS, 1894.

OCTOBER 8.

19065. **Improvements in or relating to the production of electricity.** Henry Ashur Tobias, William Henry Cadman, and Richard Joseph Crowley, 71, Shoe-lane, London.

OCTOBER 9.

19121. **Improvement in electric arc lamps.** John Edward Woolverton, 70, Wellington-street, Glasgow. (Complete specification.)

19150. **Improvements in the method of and apparatus for the electro-deposition of metals.** William Henry Beck, 115, Cannon-street, London. (Charles R. Fletcher, United States.)

19155. **Improvements in or relating to arc lamps.** Alfred Julius Boult, 323, High Holborn, London. (Paul Laminne, Belgium.)

19157. **Improvements in or relating to electric battery plates.** Henry Le Roy Bridgman, 323, High Holborn, London.

19184. **Improvements in electric heaters.** Jesse Ruckman Davis, 53, Chancery-lane, London.

19185. **Improvements in electric switches or circuit breakers.** Frank Stevens and Robert Rodwell Kesteven, 45, Southampton-buildings Chancery-lane, London. (Complete specification.)

19186. **Improvements in electric thermostatic fire-alarms.** Lewis Garwood Rowand, 47, Lincoln's-inn-fields, London. (Complete specification.)

19191. **Improved means for securing the conducting wire to the carbon electrode in elements of galvanic batteries.** Franz August von Alimonda and Nino von Alimonda, 11, Southampton-buildings, Chancery-lane, London. (Complete specification.)

OCTOBER 10.

19220. **Improvements in and relating to electric ship logs.** William David Whyte and David Muirhead, 144, Broomielaw-street, Glasgow.

19247. **Improvements in electrical ceiling roses.** George Frederick Kenyon and Edwin Moorhouse, 8, Quality-court, Chancery-lane, London.

19285. **A novel construction or arrangement of electric and/or gas chandeliers.** Martin Vincent Luis and Ernest Crawshaw Elgood, 166, Fleet-street, London. (Ludwig Priebe, Germany.)

19286. **Improvements in electric motors, and appliances connected therewith partly applicable also to electric generators.** Llewelyn Birchall Atkinson, 1, Queen Victoria-street, London.

OCTOBER 11.

19291. **Improved electric signal device.** Donald Frank Adamson and Clarence D'Oyley Hutchins, 72, Finsbury-pavement, London.

19343. **Motor vehicles for railways and tramways driven by gas or oil motor-engines in combination with electro-motors and accumulators** Charles Denton Abel, 28, Southampton-buildings, Chancery-lane, London. (The Gasmotoren Fabrik Deutz, Germany.)

19362. **Improvements in electrical safety devices.** John Smith Raworth, 46, Lincoln's-inn fields, London.

19364. **Improvements in electromotors and like electromagnetic apparatus.** Charles Connors and Walter Langdon Davies, 24, Southampton-buildings, Chancery-lane, London.

OCTOBER 12.

19387. **Improvements in magnetic shielding.** George Francis FitzGerald, 7, Ely-place, Dublin.

19421. **A method of hauling by electricity and apparatus for that purpose.** Fritz Bernard Behr, 28, Southampton-buildings, Chancery-lane, London.

19423. **Improvements in the construction of retorts or furnaces for the production of gases by the use of electricity.** John Henrique Dunn, 8, Spencer-road, Holloway, London

19443. **Improvements in the electrical production of musical notes.** Percy Tilt Letchford, 22, Southampton-buildings, Chancery-lane, London.

19444. **Improvement in electric arc lamps.** George G. Stout, 55, Chancery-lane, London.

OCTOBER 13.

19481. **An apparatus for heating water by electricity.** John William Ewart, 23, Ampthill-square, London.

19508. **Improvements in cut-outs for use in electric circuits.** Charles Philip Coote Cummins and James Leonard Golding, 55, Chancery-lane, London.

19517. **An improved apparatus for indicating the lamp-hours of electric lamps.** Robert Wende, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

SPECIFICATIONS PUBLISHED.

1888.

19045.* **Telephone-call apparatus.** Handford. (Western Electric Company.) (Amended specification.)

1890.

3900. **Insulation and cooling of electrical inductoria.** Pyker and Barnett. (Second edition.)

1893.

5505. **Electric switches, bell pushes, etc.** Watkin. (Reprint, with alterations.)

18175. **Telephone switchboards.** Franz and Otto.

18734. **Electric meters.** Olsen.

20625. **Carbon electrode connections.** Barnett.

22186. **Lock and block electric apparatus for railways.** Tyer.

22395. **Electric systems and apparatus.** P. E. and R. B. Pownall.

23283. **Connecting electric conductors.** Penson.

23331. **Electric current regulators, etc.** Cuttriss.

23337. **Electric meters.** Holden.

23385. **Galvanometers.** Jewell and Zimmerman.

24243. **Electrical arc lamps.** Lauder.

1894.

4170. **Alternating-current motors.** Thompson. (Bradley.)

4171. **Alternating-current motors.** Thompson. (Bradley.)

5754. **Electrical arc lamps.** Lauder.

6212. **Electric railways.** Cattori.

13377. **Electrolytically treating salts.** Jensen. (Störmer.)

14651. **Electrical heating devices.** Dymond. (Trudeau.)

14922. **Electrically operating semaphore signals.** Fiedler.

15900. **Shunt arc lamps for alternating currents.** Siemens Bros. and Co. (Siemens and Halske.)

NOTES.

On the Brain.—Water power—a contemporary has got it there.

"Electric" Belts.—A series of articles is being devoted in the *Bazaar* explaining how "electric" belts are made.

Dundee Institute.—The annual conversazione of the Dundee Institute of Architecture, Science, and Art will be held in the rooms of University College on November 10.

Institution of Electrical Engineers.—The annual dinner of the Institution is fixed to take place at the Freemasons' Tavern, Great Queen-street, on Wednesday, November 21.

What About Electricity?—A leading article in the *Times* states that "if one were obliged to condense the history of the nineteenth century into a single word, that word would be Steam."

Electro-Harmonic Society.—A smoking concert will be given this evening at the St. James's Hall Restaurant (Banquet-room). We gave the programme in our last week's issue.

African Cables.—The Hon. S. R. French, Postmaster-General for Cape Colony, has arrived in this country. He is endeavouring to induce the Home Government to get a reduction, if possible, in the cost of cablegrams.

A Cleric on the Electric Light.—A lecture was given the other evening at Bristol by Canon Barnett on the subject of "An Ideal City." This, he said, should be lighted by electricity. The canon has got hold of the right end of the poker.

"English Illustrated Magazine."—We have received the November issue of this magazine, which contains a well-varied collection of articles and stories, while the artistic portion is well looked after, there being numerous well-executed illustrations.

Fire at Telegraph Works.—W. T. Henley's Telegraph Works Company, Limited, inform us that the fire which occurred at their works on the 17th inst., and which was referred to in our last issue, was a small one, and in no way interferes with the working of their business.

Electric Traction in Italy.—A new conduit system of electric traction is now being experimentally tried in Turin. This method, which has been devised by Signor Alfredo Diatto, is being tested in the engineering works of Messrs. Tedeschi and Co., at the Barriera di Lanzo, Turin.

Telephony in Germany.—Telephonic communication has been established between Munich, Pasing, Ismaning, Nuremberg, Fürth, Bamberg, Bayreuth, Erlangen, Würzburg, Augsburg, Regensburg, and Berlin. For ordinary conversations the charge is 2s. for three minutes. Pressing communications, taking precedence, are charged a triple rate.

French Atlantic Cable Company.—A Dalziel cable from Paris says there is now apparently little likelihood that the proposed amalgamation of the Compagnie des Cables sous Marins and the French Atlantic Cable Company will take place. The shareholders of the latter company are using every effort to prevent the combination being carried through.

Electric Lighting in Spain.—A company has been formed in Spain under German auspices to establish a central station in Seville for the distribution of current for lighting and motive-power purposes. The capacity of the station is primarily to be for 12,000 lamps of 16 c.p., and the installation will be arranged so that it can readily be extended to 20,000 lamps.

The Franklin Institute.—The Franklin Institute, Philadelphia, has awarded the John Scott legacy premium and medal to Mr. Clement Payen, the inventor of the chloride storage battery, on the report of its Committee on Science and Arts. The report in question appeared in our issue of last week.

Athletics.—A general meeting of the City Electric Lighting Athletic and Football Club took place on Saturday at the White House, Hackney Marsh, the primary object being the election of officers, etc., for the football section of the club. Mr. Costigan occuped the chair. The officers duly elected were as follows: captain, Mr. Taylor; vice, Mr. Ebden; football committee, Mr. Mackie, Mr. Doswell, Mr. Jennings, and Mr. Barton.

British-Dutch Telepheny.—It having been suggested to the Netherland Chamber of Commerce that telephonic communication between London and the Netherlands would be a desirable addition to the existing means of communication between the two countries, the Chamber is addressing merchants and tradesmen on the subject in order to find whether the scheme would supply a trade requirement and consequently meet with support.

Coventry Technical Institute.—On Tuesday last the new buildings connected with the Coventry Technical Institute, which have been built by the trustees of Spencer's Industrial Arts Trust, were formally opened. A set of buildings has been erected costing about £5,000, and including a science lecture theatre and mechanical engineering shops. There was on Tuesday a show of telephonic apparatus, and Messrs. Philip Harris and Co., of Birmingham, had a special exhibition of chemical and scientific apparatus.

Electric Transmission in Germany.—The arrangements of the Frankfurter Societätsdruckerei, at which are printed the *Frankfurter Zeitung*, the *Wochenblatt der Frankfurter Zeitung*, and the *Kleine Presse*, are being altered so that most of the printing machines used there will be driven by electric motors. Current will be obtained from the town mains. Each machine will have an alternating-current motor attached, and these are being made by Messrs. Brown, Boveri, and Co., of Baden, Switzerland. At Königsberg the bascules of the Köttel Bridge are to be worked by means of an electric motor.

A Novel Invention.—A correspondent of the *Western Press* who is a village blacksmith writes to that paper: "I see in the *Press* something about an electrical experiment (*sic*) at Worcester, that they are utilising water power. I have made a motor which can be fixed in the Bristol Channel, and once fixed, needs no attendance whatever, not even a boy. Of course it will wear out in time. I could make a wheel to develop 100,000 h.p. It could be fixed at the new passage or any tidal river. No matter which way the tide is running, my wheel always works one way. It works automatically, and has taken me 20 years to think it."

Telegraph Extension in North Bornee.—Reuter's Agency has received from the British North Borneo Company the following communication: "The work of cutting the track for the telegraph line across the country continues to progress very satisfactorily. Some miles of posts and wire have already been erected on the West Coast We hear in connection with this important work that the track will open up some sections of land which are admirably suited for cultivation. Menumbok, on the west coast, where the Eastern Extension Telegraph Company's cable was landed, has greatly developed, a large sago factory being now under construction, in addition to the three in operation, and 36 Chinese shops are doing a thriving business."

Electro-Chemical Patents.—The Deutsche Elektrochemische-Gesellschaft, whose first annual meeting in Berlin was referred to in our issue of the 5th inst., is mentioned in a recent number of the *Elektrotechnische Zeitschrift*. It appears that the assembly had under consideration one branch of electrotechnics that has received too little attention, not only in Germany, but also in other countries. This fact is shown by the small number of patents of an electro-chemical character. The number of patents secured for any particular application of electrochemistry is, according to the journal in question, about 70 per annum in Germany, not much higher generally in the United States, and only 49 in Great Britain during 1893.

Electricity in Mining.—A meeting of the Derbyshire and District Metallurgical and Engineering Association was held on Friday evening at the Portland Arms Hotel, Codnor Park, Mr. J. T. Whitehouse, president, occupying the chair. Mr. H. B. Edwards, of Wakefield, read a paper on "Electricity as Applied to Mining," illustrating his remarks by means of a small apparatus. Mr. Edwards made special reference to the electrical plant which he has just completed at the Pollington Colliery, New Brinsley, belonging to Messrs. James Oakes and Co. A discussion followed, in which Mr. J. H. W. Laverick, manager to Messrs. Oakes and Co.; Messrs. Tomkins, Mosely, Lewellyn, of the Butterley Company; and Mr. Annable, Sheffield, and the President took part.

"**Street Railway Journal.**"—We congratulate our New York contemporary on the fact that it has reached its tenth anniversary, and on the very fine issue which it has published in honour of that occasion, and of the Atlanta meeting of the American Street Railway Association. It contains a 16-page article on Atlanta, a 10-page article on the association, a 30-page article on the street railway systems of the Southern cities, and a 20-page article on the history of the street railway industry. All of these are handsomely illustrated—containing over 400 illustrations, among which are more than 125 portraits of street railway men. There are in all 122 pages of matter, apart from advertisements, and the number is one which does much credit to technical journalism.

The Hermite System.—Speaking of the report on the Hermite system of sanitation by electrolysed seawater drawn up by Mr. Newton, the assistant engineer, and by Mr. Lindsay, the president of the Singapore Municipality, says *Indian Engineering*, said he thought there could be only one opinion expressed on reading this report—viz., that they should convey the thanks of the Commissioners to Mr. Lindsay and Mr. Newton, who he was glad to see had returned. They had supplied them with an admirable report, from which it was obvious that this system, whatever it might ultimately become, had not yet reached that stage when any practical use might be made of it here, but he had no doubt the matter would engage the attention of the engineer's department, so that if further advances were reported they would be able to reconsider the matter.

"**Electricity in its Infancy.**"—It is about time that even ignorant people should give up the use of this expression. Specially ignorant is the anonymous correspondent of a Liverpool daily, who, discussing the suggested purchase by the Corporation of the Liverpool Electric Supply Company's business, says: "Regarding electricity, this is only in its infancy, and large sums may have to be lost in gaining experience to place the handling of this illuminant on the same basis of practical knowledge that gas already stands upon. Both gas and electricity require very thoughtful consideration, and should not be discussed in the newspapers in a clap-trap style by irresponsible people of little practical knowledge of either, but simply putting into print the experience of others." The unconscious satire on himself in which the writer indulges is highly amusing. It is, however, rather surprising that he had sufficient wisdom not to make his name public.

Communication with Lighthouse Stations.—In the course of a lecture which he delivered at Carnarvon on Monday evening on "The Practical Application of Electricity," Mr. W. H. Preece, C.B., chief electrician of the Post Office, dwelt at length upon the means adopted by the authorities to establish telephonic communication between the land and lighthouses, etc. He stated that the whole of Anglesey was now so connected with the exception of two parts—viz., Llanddwyn and Llanynghenedl. With the co-operation of the Carnarvon Harbour Trust, he hoped before long to see communication established between Carnarvon and the former station, but with regard to the wretched parish of Llanynghenedl all the efforts made by the Post Office had so far been unavailing, for the required rights had been refused the authorities unless they paid a handsome rent for them. In his opinion, it was not right that any Government should be forced into competition with anyone on such a humane question as the saving of life.

The Simplon Tunnel.—The Swiss Federal Council has approved in principle the project of the Jura-Simplon Railway for cutting a tunnel through the Simplon, and the contracting firms—Messrs. Brand, Brandau, and Co., of Hamburg, Sulzer Bros., of Winterthur, and the Bank of Winterthur—have undertaken to carry out the works. The contractors have joined in a firm with the name of "La Société d'Entreprise du Tunnel de Simplon." The company contracts to complete the tunnel within 5½ years from the commencement of the works, and to throw it open for traffic with one track by that time. At the same time a lateral gallery is to be driven for a second tunnel and a second track. The Jura-Simplon Railway, on its part, undertakes to pay the contractors £280,000 for preparations; £1,900,000 for making the first tunnel with one track and a widening at its highest point for a crossing, as well as for the gallery of the second tunnel and cross galleries; and £600,000 for the construction of the second tunnel if built. The railway company has to decide within four years whether this second tunnel is to be made, for the completion of which a time of four years is stipulated. Compared with former projects, the building period has been reduced from eight to five and a half years, and the cost of construction has likewise been considerably cut down. It is not expected that Italy will pay a subvention towards the cost of the work, but it is thought probable that the Swiss Federation will exceed the grant of £180,000 already made. It will be remembered that electric traction has been recommended for use on the line.

Electric Lighting in New Zealand.—Last session the Gore Electric Light and Power Syndicate, Limited, promoted a Bill in Parliament to allow the Borough Council to grant a concession to light the borough with electricity. The current was lately turned on to the mains, and the success of the light from the two arc lamps was very pronounced. There are two arc lamps of 3,000 c.p. each, erected in the main street at about 50ft. from the ground. Private consumers are being rapidly connected on at the mains, and from the general satisfaction the light is giving the syndicate has every reason to expect a very large number of consumers before next winter. The system of distribution is the three-wire, using a low-pressure current. Two four-pole Battersea dynamos will be run when a full load is on, these being driven through Lancashire belts by two horizontal automatic engines. The engines can be run independently—either high pressure or condensing—

Digitized by Google

an independent condenser being placed between them. The boiler is of steel, 17ft. long by 5ft. 3in. diameter, and is fired with the local lignite, there being two quite independent feeds—one a Tangye duplex, taking its water from the condenser hot-well, and an ordinary donkey pump drawing from the cold-well. The engines, condenser, and steam and exhaust piping have been made by the New England Engineering and Electrical Company. The boiler was made by Messrs. Morgan and Cable, and the poles to carry the wire were supplied by Messrs. Massey and Co.; in fact, the only imported goods are the dynamos, instruments, and copper wire, of which some six miles have been used. The installation was designed and carried out under the personal supervision of Mr. R. H. Postlethwaite, M.I.E.E., and the plant is now in charge of Mr. A. Ramsay.

Local Authorities and Technical Instruction.—A return has been made to the Department of Science and Art showing the manner in which and the extent to which the councils of counties and county boroughs in England and Wales, and the county councils, town councils, and police commissioners of police burghs in Scotland are devoting funds to the purposes of science, art, technical, and manual instruction. It shows that the total amount expended on technical education during the year 1892-93 in England, Wales, and Scotland was £529,718, and that the estimated total amount allocated to technical education for the year 1893-94 was £696,328. Out of the 49 county councils in England (excepting the county of Monmouth) 41 are applying the whole of the residue received under the Local Taxation (Customs and Excise) Act, 1890, to technical education, and eight a part of it to the same purpose. Of the councils of the 61 county boroughs, 53 are devoting the whole of the residue to technical education and seven a part of it, while in one case only (the county borough of Preston) the residue is being applied, not to educational purposes, but to relief of rates. In addition, the councils of 10 county boroughs are levying a rate, or making grants out of the rates, under the Technical Instruction Acts. The 13 county councils and the councils of the three county boroughs in Wales and Monmouth are devoting the whole of the residue to intermediate and technical education, chiefly under the Welsh Intermediate Education Act, 1889. In addition, the councils of six counties and county boroughs are levying a rate or making grants out of the rates under the Technical Instruction Acts. In the case of Scotland, 23 out of the 33 county councils are applying the whole of the residue to technical education and seven a part of it, while one has the matter under consideration, and two are applying the residue to the relief of rates. Of the 194 burghs and police burghs, 21 are applying the whole and 50 a part of the residue to technical education; one has not decided, and 122 are applying the whole to the relief of rates.

Sir F. Bramwell on "Science."—The distribution of prizes and certificates to the successful students at the Westminster Technical Institute took place on Monday. Sir Frederick Bramwell delivered an address, in the course of which he said that the students before him had sufficiently proved their knowledge of the value of the institution to which they belonged by the fact that in four or five years their numbers had increased from 20 to 1,000, a result which could hardly have happened unless those who had made that increase believed they were doing something for their own advantage. When he was a boy his master taught him all he could teach, and that embodied a good deal of practical work, without much theory. The fact was that theory was not taught by his master, because he had no theory to teach. What they had secured in the institutions of the present day was not only a substitute for what was imparted in by-gone days, but included a great deal of information which could not formerly be obtained. They now saw why they did certain things, and why certain results followed. Formerly they only did what they were taught, because their forefathers had done the same things for generations. But though it was well to know why results happened, they ought not to despise practice. He was one of those who believed that if, from generation to generation, good iron was made from the iron ore of a particular district by a certain process, it was better to follow that process than to depart from it at the bidding of a scientific man. Indeed, if a philosopher told him that that which had answered for generations was entirely wrong, he should begin to doubt whether the philosopher had not lost sight of a bit of his philosophy. He would, however, advise his hearers not to despise the beginnings of science, trivial though they might seem at first. They should remember that it was not so very long ago when a man in an Italian city found that, by a certain arrangement of metal plates, he could cause a frog's legs to kick. People then said: "It might be wonderful, but what was the good of it?" Well, the good of it had since been amply demonstrated, and one of the illustrations of what might be got from a new scientific fact was to be found in the lighting up of that large hall by the incandescent electric light.

The Pacific Cable.—The failure of the negotiations with Hawaii for the purchase of Neckar Island as a station for the proposed Pacific cable, says a Reuter's telegram, has given rise to varied Press comments at Ottawa. Under the heading of "British Blundering," the *Ottawa Citizen*, after pointing out how necessary for the success of the Pacific cable scheme it was to secure the island, says: "There is a general belief that the Canadian Government urged upon Great Britain the necessity of taking possession of this desirable spot while it was still no man's land, and months before its capture by Hawaii. The Home Government, with that incredible apathy which sometimes marks its treatment of the most important affairs of and outside the empire, neglected the favourable moment, and allowed a foreign Power to step in and seize the coveted prize. Is Great Britain unequal to the responsibilities entailed by her great possessions? Whatever the cause, the stupid negligence and procrastination exhibited in such matters as that of Neckar Island are particularly exasperating to us in the colonies, who are putting forth every effort to bring together the possessions beyond sea of Great Britain, and who expect that at least as keen an interest shall be taken in the schemes for that purpose at the heart of the empire as is felt here." A Reuter's telegram from San Francisco dated 24th inst., says: "Mail advices received here give the following additional information respecting the negotiations entered into with the Hawaiian Government by Mr. Mercer, of the British Foreign Office, and Mr. Sandford Fleming, one of the directors of the Canadian Pacific Railway, regarding the proposed Pacific cable. The two commissioners ask Hawaii for a lease of Neckar Island and for a subsidy of £7,600 for 15 years. In return, they will lay the cable, and make the rate 1s. a word over the line and a special Government and Press rate on condition that Hawaii cede the island to Great Britain in the event of a Hawaiian annexation to the United States. The Hawaiian Government, it is added, is willing to consider the proposal if the commissioners accept a lower subsidy and forego the provision for the session of Neckar Island to Great Britain in the event of annexation."

Information Concerning Electric Light.—The following circular has been issued by direction of the Electric Lighting Committee of the Hammersmith Vestry: "The Vestry of Hammersmith having obtained their provisional order in Parliament as undertakers for the supply of electricity to the Hammersmith area, and also a complete report on a scheme for the proposed undertaking, are desirous of gauging approximately the amount of support they are likely in the first instance to obtain, in order that the initial outlay on the works may be regulated accordingly, and utilised to the best advantage. The Electric Lighting Committee, therefore, would be glad if probable consumers would fill up the enclosed form in order to enable them to obtain this information. The committee also append the following notes as a guide as to the cost of installation and working of the electric light and the method of supply generally: (1) Private supply service—The supply of current (at low pressure) will be continuous day and night, and the light will therefore be available at all times. (2) Cost of current—An 8-c.p. electric incandescent lamp may be taken as effectively replacing an ordinary gas burner consuming four cubic feet of gas. Electricity will be supplied at 6d. per unit, and the consumption measured by meter. At this rate an 8-c.p. lamp costs rather less than ¼d. per hour. From statistics compiled by Mr. W. H. Preece, C.B., engineer-in-chief to the General Post Office, as to comparative cost of gas and electricity in nine chief towns of the United Kingdom, it has been ascertained that, light for light, gas rated at 3s. per thousand cubic feet is equivalent to electricity at 6d. per unit. (3) Initial cost of installation—The cost of wiring and fittings depends upon the premises wired, number of lamps installed, and the individual taste of the consumer. It may be done effectively for 20s. and upwards per lamp. (4) Other uses of electric current—The current may be used for every kind of lamp, arc or incandescent; also for motive power, cooking or heating, and special reduced rates will be offered for current used for these latter purposes. (5) Streets to be first served—The following is a list of streets in which electricity will be first supplied by the Vestry: King-street, from Broadway to Ravenscourt-park; Broadway; Hammersmith-road, from Broadway to St. Paul's Schools; Queen-street, from Broadway to further side of St. Paul's Church; Brook Green-road; Shepherd's Bush-road; Shepherd's Bush Green; Goldhawk-road, from Shepherd's Bush Green to Starch Green-road; Uxbridge-road, from Uxbridge-road Station to Percy-road. If it be desired that electricity should be supplied in other streets in the parish, the Vestry will be prepared to consider applications if made under the terms of the provisional order by a sufficient number of owners or occupiers in any street."

Electrical Advertising.—We have previously referred to some amusing protests which made their appearance in some of the daily papers at the time when the electric advertising projector first made its appearance in Trafalgar-square, and apparently the protestors had resigned themselves to the inevitable. However, all at once a certain "L. H. M." has bobbed up serenely in the correspondence columns of the *Times* with the following comic letter: "I beg you to grant me a little space to add one more to the (unfortunately) few letters which have already appeared in the leading papers in defence of a cause which should require no pleading from Englishmen. I refer to the scandalous and incredibly unpatriotic way in which one of our finest monuments, raised to the memory of the greatest sailor and one of the greatest heroes that ever graced a page in English history, is being made the means of advertisement of some vendor of 'patent foods' whose name is unknown to fame, and justly so. I refer to the Nelson Monument in Trafalgar-square, on which every night an advertisement, some 20ft. high, is made to pass backwards and forwards by means of an electric search-light. Where is this mania for advertisement to stop? Our streets and public buildings, and even the rivers and fields, are desecrated and made hideous by boards of all colours, and yet, not content with these means, the advertiser of to-day must lose all sense of honour and patriotism and attack our monuments, which should be as sacred as the walls of Westminster Abbey. Can nothing be done to prevent this disgrace? Such an insult to a nation would not be permitted for one moment in France or in Germany; but England is a 'free' country, and therefore nothing is done! All I can say—and I am sure I echo the sentiments of many others—is that, if such things as these are to be the outcome of our much-vaunted 'freedom,' Englishmen will soon have little reason to be proud of their birthright." Of course, if, as stated by this writer, the name of the vendor of patent food is unknown, that shows his good sense in obtaining such an effective advertisement. Another gentleman, writing lately to the *P. M. G.* (not the Postmaster-General, but the *Pall Mall Gazette*), suggested that someone should go to Trafalgar-square with a more powerful projector and blot out the advertisements by that means. This would, of course, all be good for the electrical trades. Yesterday a Mr. John Richmond, styling himself "hon. treasurer N.S.C.A.P.A."—whatever that means—wrote to the *Times* as follows: "This society has been moved by its own members, by the Vestry of St. Martin's-in-the-Fields, as well as by sympathy with the protests which have appeared in the Press, to endeavour to discover a means of checking the vulgar disfigurement of Trafalgar-square by electric flash advertisements which is now of nightly occurrence. The feeling aroused against this scandalous abuse of public monuments is wide and growing, and if Parliament were in session something would probably be done at once to check so obvious a nuisance. But in the meantime we have got counsel's opinion that 'the owners of the buildings afflicted by the advertisement can proceed for trespass or nuisance.' A short clause amending the Metropolitan Police Act of 1839, and extending its control to this form of advertisement, could be passed when Parliament meets. But must we wait till then? Cannot the County Council or the First Commissioner of Works do something for us at once?"

Electric Lighting in Germany.—The central electric light station at Salzungen, which has been erected by Messrs. Schuckert and Co., is so far ready that an experimental run has been made. Current will be supplied both for street and for private lighting. Mr. Beck, of Esslingen, has proposed a scheme to the Municipality of Göppingen for the erection of a central station. The small town of Oberehnheim is receiving the electric light. Overhead conductors fixed on high poles are being employed. The Municipality of Barmen have decided to instal the electric light in the buildings of the advanced school. The Emperor William Memorial Church, Berlin, will be the first in the city to receive the electric light for internal illumination. The new Peter Church at Frankfort-on-the-Maine is also to be lighted electrically. The central electric light station at Frankfort is virtually completed. The electric lighting mains are being extended in the town of Hanover. A commencement has been made in connection with the central electric light station at Bergedorf. The neighbouring community of Sande-Lohbrügge propose either to take current from the Bergedorf station or else to establish a plant of their own. Mr. R. Genge has received the concession to erect a central electric light station at Schwerin-on-the-Warthe. It will have a capacity of 1,500 incandescent lamps and 50 arc lamps, and the work will be

Digitized by Google

carried out by Messrs. Lehmann and Mann, of Berlin. The Allgemeine Electricitäts-Gesellschaft, of Berlin, is erecting an electric light plant for the whole of the buildings of the Eastern Railway Station, Königsberg. There will be about 50 arc lamps and 500 incandescent lamps. The work in connection with the central electric light station at Graz is nearly finished, and it is expected that it will be opened next month. The annual report of the Berliner Elektricitätswerke Aktiengesellschaft for 1893-94 states that the number of consumers is now 2,580, of lamps 194,400, and the consumption of current 57,500,000 ampere-hours. The number of motors connected has risen from 232 of 786 h.p. to 380 of 1,364 h.p., and since the termination of the business year there have been added 70 of about 300 h.p. The gross profits amounted to £144,016, and the net profits to £64,653, out of which a dividend of 10½ per cent. has been declared. A central electricity station has been opened at Flensburg. The installation comprises four compound steam-engines of from 80 h.p. to 120 h.p., seven tubular boilers, and eight dynamos of 130 volts and 200 amperes. A battery of accumulators is also to be provided. The station has a capacity of 4,000 lamps of 16 c.p., and can be extended to 7,000 lamps. The local authorities of Nuremberg have again had under consideration the question of the electric lighting of the town, two schemes having been drawn up by Mr. Oscar von Miller. They are in favour of the alternating-current project. Messrs. S. Schuckert and Co. are to be asked to make a tender. Representatives of the three firms—Messrs. Siemens and Halske, Messrs. Schuckert and Co., and Messrs. Kummer and Co.—who are to unite in carrying out the central electric light station in Dresden have met there to discuss the details. The villages of Elzach and Singen propose to establish a central electric light station, and a deputation has visited Triberg to inspect a local plant. The Municipality of Kaiserslautern have decided to light the streets by means of 25 arc lamps. Mr. Pebermann intends to light his mill at Neustadt electrically. The Municipality of Strasburg, West Prussia, are going to erect a central electric light station in connection with their slaughter-house. The building will be carried out by the town, and the plant will be supplied by the Helios Elektricitäts-Gesellschaft, of Cologne.

Transatlantic Cables.—The following item from the *Scotsman* indicates the difficult position of pluralist directors when the interests of their various companies come into conflict: "The fusion of interests which has been established between the French Submarine Cable Company and the Paris to New York Cable Company is destined to have an unfavourable influence on British submarine telegraphic interests. There has been a good deal of agitation in the Paris Press with the object of urging the Government to give the combined undertaking pecuniary aid for laying another Transatlantic cable. The present French cable is quite out of the race in the competition, and seriously injured itself when it broke away from the pooling arrangement. That the combined undertaking will greatly benefit by putting down another cable is doubtful. There are already a dozen lines across the Atlantic, eleven of which are working. Of these, four are owned by the Anglo-American Company, three by the Commercial Cable Company (now leased to the Western Union), one by the Direct United States Cable Company, two by the American Cable Company, and one by the Paris to New York Cable Company. The first three companies pool their receipts, while the others work independently. This would at first sight seem to be all sufficient—more than enough, in fact, seeing how unremunerative is the business, especially to the premier company. But the project of the French companies to lay another cable is not the only new one of the kind. It has been virtually arranged to lay down a German cable. As regards the French scheme, there is a certain amount of good reason for it. In the first place, the existing line might at any moment break, and communication between France and the United States would depend wholly on the Anglo-American Company. At the present moment the latter company does, as a matter of fact, attract a good deal of the French business owing to its alliance with the Western Union, which controls the land lines across the Atlantic. But there is another reason for this anxiety to establish another cable. By the amalgamation of the two French companies it is hoped to attract a great deal of distant traffic from which it is at present virtually cut off. Thus the Submarine Company has 6,754 kilometres of lines which knit together Cuba, Hayti, San Domingo, Martinique, Guadeloupe, Dutch Guiana, French Guiana, and taps Brazil at Para, Venezuela, and other ports. To send messages from Brazil to the United States over the company's wires is, however, more expensive than to forward them to Europe, and thence over the English lines to the United States. Consequently there is a scheme to form a junction with the cable of the French Transatlantic Company, so as to make a complete circuit. This scheme, it may be taken for granted, will be carried out. As regards the scheme for a German cable, this will need the close attention not only of the shareholders in the Anglo-American Company, but of those also in the Globe Telegraph and Trust Company and the Submarine Cables Trust Company. The German Government have all but agreed to grant an annually subsidy of £70,000 per annum for such a line, the right having been obtained by the concessionaires to touch at Lisbon and the Azores. As, however, the German Government are bound by their contract to use the Anglo-American Company's system until 1900, the affair is some way off. The singular point is that the Eastern Telegraph Company has obtained the right to exploit the cable from the original concessionaires, and its present purpose is to carry out the scheme. The competition will naturally be severe. Yet the same directors sit on the Boards both of the Anglo-American and the Eastern Telegraph Companies, so that they purpose to rule the destinies of two rival concerns. But this is not all. The chairman of the Anglo-American Company is also on the Board of the Globe Telegraph and Trust Company, and of the Submarine Cables Trust Company, which concerns have an interest to the extent of about £1,750,000 in the Anglo-American, the Direct United States Cable, and the Commercial Cable Companies, whose business is to be cut into by the German project. The cost of this competition to the Anglo-American Company will probably not be less than £70,000 per annum, which is equal to about 1 per cent. of dividend, or half what it is now paying. The directors seem to allege that by starting this competition with their existing companies, they will make it less severe than if it fell into outside hands. But to this the obvious answer is that they will be bound to give all their Eastern business which now goes over the Anglo-American system to their new concern, whereas an outside company would not have such an advantage. Besides, to speak of not driving the competition too hard is equivalent to a promise that the interests of the shareholders in the new enterprise are to be in some measure sacrificed, which hardly seems just. But whatever may be the ultimate arrangement, it is certain that a desperate Transatlantic cable fight is in prospect, and that existing interests must suffer severely."

ELECTRICITY AS A MOTIVE POWER.

In our issue of August 24 we gave a paper read before the Iron and Steel Institute at the Brussels meeting by Mr. D. Selby-Bigge on "Electricity as a Motive Power." In this paper Mr. Selby-Bigge described the Herstal installation. Owing to the want of time the paper was not lengthily discussed at Brussels, but since then Messrs. Charleton, Richards, and Thwaites have contributed lengthy criticisms on the paper, which appear in the institute's *Transactions* as follows:

Mr. A. G. CHARLTON considered the author's paper one of exceptional interest to engineers—not only to those engaged in the iron and steel industries, but to many who, like himself, were more particularly connected with other branches of metal-mining at home and abroad. As an example, he would mention that, whilst recently engaged in laying out a large mining and dressing plant in the Pyrenees, he was very much struck by the immense use to which electricity might be applied in several different ways: (1) to drive the machinery at the mine, which was situated at a high altitude, in a position rendering it somewhat inconvenient, and indeed difficult, to employ steam or other forms of power transmission; (2) for lighting the works; (3) for the magnetic separation of the ore, the employment of electromagnetism rendering it possible to produce a marketable zinc blend from low-grade material (carrying magnetic iron), which would otherwise have been unsaleable.

There was, however, it should be mentioned, the very great advantage of splendid water power in the neighbourhood conveniently situated to operate turbines or Pelton wheels for current-generating purposes. Until he read Mr. Selby-Bigge's paper he was certainly under the impression, however (as he believed most engineers were), that where the advantage of water power could not be commanded, electricity was in most cases only commercially applicable for long-distance transmission. The economy which should result where steam was used, both in fuel consumption and labour, with the various minor advantages the author claimed (through laying out works in the manner he suggests), had indeed not impressed him with the force they now did, in view of the very clear manner in which the matter was put in his paper. One paragraph in particular was of special interest—namely, that "few engineers really realise what is actually lost in the transmission of power through long lines of main shafting, countershafting, pulleys, belts, etc. The power lost has often been ascertained to vary between 30 and 69 per cent. of the total power transmitted."

In a paper recently read before the North of England Institute of Mining and Mechanical Engineers, "On the Choice of Coarse and Fine Crushing Machinery and Processes of Ore Treatment," he took occasion to say "that it appeared to him we must look for advancement in the future rather towards perfecting the details of the machinery and processes we at present possess, than to the discovery of new principles. "We might substitute, for example, a small motor of the Diehl type for the flywheel, belt, and pulley of a rock-breaker, or other machine, and drive it direct in this way, perhaps with advantage in some situations." Now, when he made that suggestion he was entirely unaware that anything had been done practically in this direction, and he was extremely glad to find the feasibility of the idea confirmed and actually applied on a large scale, where power had to be distributed amongst a number of machines and belt transmission was inconvenient or costly. The advantages of electricity for power transmission were daily becoming better recognised in the mining districts of the Western States of America, in localities where water power could advantageously be turned to account. In that connection it might possibly be of interest to members of the Iron and Steel Institute if he mentioned what had been done in two notable instances.

I. The plant of the Aspen Mining and Smelting Company, of Pitkin, Colorado, which was the first mining company in America to use electrical power for hoisting. The mines where this plant was erected were situated on the north-west flank of a mountain which presented a slope of about 28deg. The ore, which was found at the contact of a mass of blue limestone with an underlying bed of dolomite, dipped north 30deg., west at an angle of 60deg., and was reached by an adit (driven south into the mountain at a vertical depth of some 500ft.) about 1,000ft. in length, given a grade of 3 in 100, which was used for both drainage and transport. In order to develop this ore body, drifts were run right and left from the inner end of the adit tunnel along the strike of the deposit, and to incline planes were sunk with the idea of sinking them to a considerable depth. One was begun near the inner end of the adit-level, the other 300ft. distant in the drive north of it. Power of some kind being necessary to raise the ore and waste materials ("deads") to the main tunnel level, it was decided to try electricity, as both steam and compressed air offered serious objections. Accordingly, a "flume" was constructed to carry the water of the neighbouring mountain streams to a 5ft. Pelton wheel, under an effective head of 63ft., and a 50-h.p. 500-volt constant-potential Edison dynamo was installed in connection with it, at a distance of 6,000ft. from the mouth of the tunnel. The hoist, which consisted originally of a 7½-h.p. street car motor manufactured by the Sprague Electric Railway and Motor Company, was placed at the head of the Veteran tunnel July, 1888, and was provided with an auxiliary drum to draw the empty cars in the tunnel by a tail rope system, the loaded train running out by gravity. Notwithstanding the trying conditions under which this plant was operated, one of which was the condensation of moisture on the machine owing to the dampness of the workings, it proved a success. The iron pinions on the armature shaft were, however, exchanged for raw hide pinions, which diminished the noise when running, and the liability of leakage of current to the levers and other parts of the machinery, and it worked so successfully that a second hoist was placed at the head of the other incline. Each of these hoists was designed to raise 250 tons 250ft. up a 60deg. incline every 24 hours, reckoning 16 hours' actual work. The original motor had been in use for three years in the autumn of 1891, during which time the cost of repairs is stated to have been as follows:

Replacing field-magnet coils	£8	6	0
Rewinding one armature	16	0	0
Replacing commutator	15	0	0
	£39	6	0

That statement did not include the small item of commutator brushes, the copper brushes first employed being responsible for the last item of repairs mentioned. Since the adoption of carbon brushes the motors have run without "sparking" and the wear upon the commutators was inappreciable. The burning out of the insulating material on the field-magnet coils might have resulted from one of several causes, whilst the bursting of the binding wires on the armature could have been guarded against had it been anticipated. An extra armature that can be used in either motor hoist was now, however, kept on hand in case of accident. The total time lost in making the repairs alluded to was 12 hours. In 1890 the Aspen Company decided to erect a generating plant of its own (the original one, belonging to R. F. Electric Light and Power Company), and they erected for this purpose four 42in. Pelton wheels, set in pairs on the same shafting. Each wheel was actuated by a double nozzle, which discharged the water in two streams, at a pressure of about 35lb. per square inch, obtained by utilising an effective fall of about 80ft. The flume which carried the water to the head of the pipe had a capacity of 1,000 cubic feet per minute, and a length of 1,300ft. The plant was coupled to two 50-h.p. Thomson-Houston motor-type dynamos wound for a constant potential of 500 volts generating 100 e.h.p. The power generated in this way was automatically regulated to the demand made upon it by deflecting the waterwheel nozzles (which work on a ball and socket joint) by means of a Woodward governor, set to maintain a constant speed of the waterwheel shaft from which it was actuated. The wheels were enclosed in an iron hood 4ft. by 4ft., which could be removed with little trouble, the joints being made tight with rubber gaskets. The adjoining ends of the

Digitized by Google

waterwheel shafts carry a friction clutch, by which they could be run as one when it was desirable to apply the motive force of both dynamos to the one common line, and the dynamos were connected with the switchboard in the generating station by overhead wires hung from the trusses. The current was conveyed from the power station to the tunnel 6,000ft. by bare 0·0 copper wire, except for a short distance (about 300ft.) at the end of each line, where an underwriter's insulated wire of the same gauge was used. Inside the mine the current was conducted to the hoisting stations, a distance of 1,000ft. and 1,200ft., by kerite seven-strand conductors, having a heavy insulation $\frac{14}{32}$in. in diameter. Okonite or Grimshaw insulated wires were used in all the circuits inside the mine, where the insulation must necessarily be of the best, and in none of the interior circuits was there a loss of more than 5 per cent. The loss on the outside circuit carrying the maximum load required, up to the time these particulars were given, was 5 to 6 per cent. The cost of generating current (not including interest or depreciations) obtained by dividing the cost of labour and lubricants by the horse-power required, was found to amount to two-thirds of one cent per horse-power per hour, but greater amounts of power could be furnished at a lower rate per horse-power; as up to 100 h.p. no increase of plant would be needed, the cost of labour would remain the same, and the cost of lubricants would not be much increased. In July, 1890, Mr. F. G. Bulkley, the manager, put in an electric diamond-drill, operated by a 3-h.p. Thomson-Houston motor, designed to bore 400ft. holes $\frac{15}{16}$in. in diameter. It was used for 12 months to explore the hard blue, often silicified, hanging wall of the Aspen mine, and the brown dolomitic footwall, and drilled, it is stated, at the rate of 1½in. to 2in. per minute, or in a shift of eight hours, allowing for delays inseparable to such work, from 6ft. to 32ft., depending on the character of the rock. The average progress, allowing for time lost in setting up and drawing cores, was put at 15ft., and it was served by one man with a helper; 4,400ft. were drilled by this machine from starting to July 6, 1891, at a cost, inclusive of all expenses, of 68 cents per foot. Subsequently a 25-h.p. C. & C. electric motor was substituted for the original 7½-h.p. hoist erected at the head of the main incline. This machine was geared to raise a load of 3,000lb. up a 60deg. incline 275ft. per minute, and had been proved capable by trial of making the round trip, from a depth of 550ft., in three minutes, with the full load. Electrical power was now, he believed, applied at the mine to run a small machine-shop, saw-mill, and wood-working machinery, and the company proposes to employ an electric locomotive for surface conveyance, and to make trial of a Thomson-Van Depoele electric percussion drill, a motor-transformer supplying the drill with a current of 220 volts taken from the 500-volt mains. The main levels of the mine are lighted by electricity taken from the power mains, employing five or six 100-volt incandescent lamps, connected up in series, which absorb about 8 h.p. electrical energy.

Mr. M. B. Holt summarises the advantages of electrical power for mining operations in his account of this interesting installation by remarking: (1) that it can be transmitted long distances with small loss, thus making it possible to use power at such a distance from its source as would render it otherwise unavailable, as in the case before us; (2) the conductors for conveying electrical power from one point to another require less space, are more easily put in place and repaired, are easily tapped for branch circuits, and form a more flexible system throughout than any other mode of transmission permits; (3) the electrical system is ideal viewed from the standpoint of cleanliness; (4) the stations for utilising electrical power can be made to occupy a minimum space; (5) if this system does not assist ventilation, it does not, on the other hand, vitiate the air in mine workings; (6) after three years' use under varying conditions of mining work, the electrical current of 500 volts has proved itself to be free from danger to life, and has caused no inconvenience further than one or two severe shocks.

II. The second notable case he should like to instance was "the plant" of the Standard Consolidated Company of Bodie, California, they having lately erected an electrical power plant to run their 20-stamp mill. In 1891 milling cost them on an average 3·89 (16s. 2½d.) per ton, crushing about 1,309 tons per month, and as the price of fuel was 10dol. per cord in this locality, their fuel bills frequently exceeded 2,000dol. a month. On this account, and for other reasons, it was decided to try electricity. An excellent water power was found at Green Creek, a mountain stream on the northern slope of Castle Peak in the Sierra Nevadas, forming one of the chief feeders of Walker River, and an arrangement was made for a perpetual right to its use, for power purposes, on very favourable terms. This stream carried 500 miners' inches of water at its lowest stage, and ran six or seven times that amount when the snows melt in "the spring." An old ditch was cleaned out, and practically rebuilt for a length of nearly a mile, and a site selected for a power-house, 355ft. vertically below the lower end of the ditch. The work of cleaning the ditch, building dam, head-gate, waste weirs, flume, penstock, and power-house, and of laying and anchoring the pipe was pushed during the months of August, September, October, and in November, 1892. The waterwheels were put in place, so that by December the water-power plant was completed and ready to run. A pole line was constructed following a straight line, 12 miles in length, over the mountains from the power-house to the mill, upon which to hang the wires, and 14 miles of telephone line was built between the Bodie office and the power-house, but at a distance from the power line, in order to avoid induction and consequent bad service of the telephones. The motor foundations were also put in at the mill, and a motor-room 26ft. by 18ft. was built, whilst the necessary countershafting and pulleys for making the connection between the motor and battery shafting were made ready to put in place. Lumber from the old Bulwer Standard Mill and other material was used in the construction of the works at Green Creek, thereby greatly reducing the cost. The power-house, 30ft. by 40ft. in size, was the former mill salt-house, and the penstock was one of the water-tanks at the mill, while the steel receiver at the lower end of the pipe was made at the mine from an unused steam-drum. The ditch was 4,558ft. long and was connected with the penstock by a short piece of flume fitted with the usual screen, sand-bore, waste-weir, and flushing-off gate. The pipe was led into the above-mentioned steel receiver, 40in. in diameter by 9ft. 8in. long, from which four taper pipes carried the water under pressure of 350ft. vertical head to as many 21in. Pelton waterwheels, each pipe being fitted with two nozzles and each wheel capable of developing 62½ h.p. The wheels ran at 865 revolutions, and the wheel shaft was connected by a patent insulating coupling to the armature shaft of a Westinghouse 120-kilowatt alternating dynamo generating current at 3,530 volts. A Doolittle governor was attached to the wheels, and a No. 2 Pelton motor had also been put in to run the "exciter" necessary for generating the initial current in the fields of the large machine. The poles of the line are of round tamarack timber 21ft. long, 5in. in diameter at the top; 25ft. poles being used in the town and where the ground required it. They were spaced 100ft. apart, and fitted each with a 4in. by 6in. by 4ft. cross-arm, boxed into the top of the pole and fastened with one bolt and one lag-screw. The wire was No. 1 B. & S. gauge soft-drawn bare copper, and was attached to standard double-petticoat deep-grooved glass insulators carried on Klein ¾in. by 8in. pins. The wire used was of large section, but the distance of transmission was just at that half-way point where the cost of converters about equals the difference in price between a No. 1 and No. 6 wire, hence it was considered better to use a higher potential and a large wire and avoid the complicated and often troublesome converter. The loss of potential on the line was estimated at 15 per cent., and the current delivered to the motor will therefore be 3,000 volts tension. The motor was 120 h.p., and would be brought up to speed by a small motor of 3 h.p. to 4 h.p., which was built on the same bed-plate as the larger one, and thrown out of circuit as soon as the latter was at proper speed, running in synchronism with the generator at the power station. Two "transformers," ratio 30 to 1, of a capacity of 100

Digitized by Google

incandescent lights each would be used for lighting the mill and offices at Bodie. The cost of this plant was given as follows:

Water power, including ditch, pipe, waterwheels, etc.	£1,783
Wire line (12·46 miles) £168 per mile	2,095
Motor-room, countershafts, and pulleys at mill	358
Telephone line (14 miles) 78dol. 52 cents per mile	220
Sundry expenses	61
Dynamos and electric plant	2,242
Total	£6,759

The plant was not ready to run till October, 1893, owing to various unlooked-for delays, but during that month it ran continuously with the exception of two days, and the saving effected was clearly shown by the cost of milling that month—viz., 9s. 8d. per ton, as against the average cost for the preceding eight months of 15s. 9d.—a difference in favour of the electric power of 6s. 1d. The mill was operated by electric power all through December, effecting an almost equal saving, but trouble was experienced in November, and again in January, 1894, due to the freezing of the water-ditch. In concluding his report for the year ending January 31, 1894, Mr. T. H. Leggett, the manager, says: "We have the advantage now of being able to operate the mill by electric power, enabling us to work a higher grade and less quantity of ore without the loss of time and money accompanying each start and stoppage of the mill when the same is being driven by steam power. This aside from the direct saving in fuel consumption of from £7 to £8 per 12-hour shift." The idea of utilising the surplus waste gases of blast furnaces for firing boilers to generate electrical work in districts like Cleveland appeared to be a very valuable one, capable of large practical application. The absolute checks over the coal consumption and running expenses which electric power afforded, indicating exactly what the various machines in the works were doing, were certainly features which should recommend it to consideration.

Mr. L. RICHARDS, referring to that portion of the paper dealing with the application of electric motive power in place of steam at the blast furnaces, steelworks, and rolling mills, thought that the author over-rated the amount of the waste gases that would be available after the requirements of the blast furnaces had been supplied. But would there be any advantage derived from the use of electricity as a motive power, rather than steam, in the blast-furnace department, beyond possibly driving overhead and perhaps other travelling cranes, and, of course, the lighting? Pumping water for lifts and other hydraulic machines constituted most that was to be done by motive power outside of the blowing engines. In pumping machines generally the motive power was made to produce rectilinear motion direct, rotary motion playing only a small part—that was to say, the pressure of the steam on one piston was made to act direct upon another piston, or plunger, as the case might be, so as to force the water into the accumulator and the tanks, a light flywheel in some instances having been used to clear over dead centres, and to ensure regular running. It was difficult to see how any advantage was to be gained by the substitution of electric motive power for that of steam direct in machines of that class. Coming to the steelworks and rolling-mills, the author stated that the coal consumption per horse-power of work turned out was from 8lb. to 15lb., and even more. In another place, when referring to rolling-mills, the consumption of coal per indicated horse-power was given as 7lb. to 8lb. It would be very interesting to know how these figures have been arrived at, especially those giving the horse-power upon the work turned out. With regard to the figures (7lb. to 8lb.) given as the consumption of coal per indicated horse-power per hour, they seemed abnormally high. He presumed that the indicated horse-power had been calculated from full work diagrams, and from an assumed uniform piston speed for the minute of time. That, however, was not the case with reversing engines. With regard to the figures given as the horse-power upon the work done, or rather turned out, he was well aware of great injustice being done to rolling and other engines in connection with rolling mills in this respect, owing to the irregular system of working. It was the system of working that was mostly at fault. The stokers at the boilers never knew when the work was coming on, and so they dared not bank the fires, or even slack firing, and the consequence was that much fuel was burnt to no purpose. With the same system prevailing, it was difficult to see how matters could be any better with regard to firing the boilers supplying steam for the engines of the electric generators.

The author characterised all the engines in connection with rolling mills as uneconomical, using low-pressure steam, with little or no cut-off. But he (Mr. Richards) failed to see any reason whatever why all the engines in a rolling mill, with the exception of the reversing engines, should not be economical as regards steam consumption. There was nothing in the way of having early cut-off, or of having compound or triple expansions, nor of having steam of 150lb. per square inch, or any other desired pressure, if suitable boilers were put up. Nor was there need to have any long lines of steam-pipes to connect the auxiliary engines with the main boilers, as managers have of late years been fully alive to the advantages of utilising the waste heat of the heating furnaces for generating steam, and making direct steam-pipe connections between the furnace boilers and the auxiliary engines. Under the circumstances detailed, it was again difficult to see the advantage of electric mover power over that of steam direct. Most engines such as were tabulated in the paper had to do a great variety of work in which the power absorbed varied between very wide limits, and hence it was necessary to provide power for the heaviest, and often more or less unknown work, and if the engine was provided with an automatic variable cut-off, nothing could be much amiss. The employment of electric motors for doing the same class of work would be under similar circumstances—that was, a punching machine or a straightening press would be dealing with a light section at one time and a very heavy one at another—so that it appeared that to take an electric motor to measure the power absorbed at any one time, would be of little value for determining what the permanent motor should be.

With regard to the application of electric motive power for driving reversing rolling mills, the author spoke with what he (Mr. Richards) considered proper reserve. Being well acquainted with the reversing rolling-mill engine from the time of its introduction, he was of opinion that there was no other engine, not even the marine engine when working under the most trying circumstances, that could be compared with it as regareded the work it had to do and the manner it had to be driven. Owing to the long stroke of 5ft., which was very commonly adopted, the piston speed ran up to 1,000ft., and even 1,200ft. at times, and it had to be reversed from 12 to 15 times in about every 2½ minutes. With an electric motor running in the manner just described, there would, he thought, be some considerable difficulty in governing the electric generator with the energy taken from it in great gulps at one instant, and none in the next. The effect upon the motor driving the rolls was also difficult to foretell. There was, however, no doubt that the reversing rolling-mill engine was susceptible of improvements as regarded economy in the consumption of steam. There was, too, room for great improvements in the mode of generating steam for it. He had long thought that the cylindrical multitubular marine boiler, or any other boiler in which there would be a maximum concentration of evaporative power, with a minimum of occupied space, should be adopted. Such boilers would admit of being placed close to the main engines for which they were to supply steam, and the great loss of heat, not only from condensation in the present long lengths of steam-pipe connections, but also that from conduction from the external flues of the Lancashire boilers, through the brickwork surrounding them. Also the heat absorbed in the brickwork itself, and in the great weight of water contained in a large battery of such boilers, which for the most part was thrown away when they were let out at the end of the week, and had to be replaced at the time of relighting, would be saved.

(To be continued.)

ELECTROLYSIS OF WATER-MAINS.*

BY G. H. BENZENBERG.

Since the last meeting of this association the subject of corrosion and the destruction of water-mains, gas and service pipes, cables and other underground conductors in streets where electricity has been introduced as the railway motive power has, at the hands of the various engineers and the chemists, received a much more scrutinising and scientific consideration by closer investigation or by experiments and laboratory tests; and thereby much of the mystery which seemed to surround this destructive process some 12 months ago has been removed. The doubt which seemed to exist in the minds of many as to the corrosive action occurring only at such points where the current left the enforced conductor has been entirely removed, and the fact established that only where the pipe or cable is positive to the earth and to some other conductor, and where the pipe or cable assumes the position of an anode to that other conductor, be it the rail, some other pipe or cable, or the generator itself as the cathode, with the intervening earth as the electrolyte, that corrosion takes place by electrolytic action. It has also been established in experiment by more than one investigator that it needs but an extremely low potential, not exceeding one-hundredth of a volt, coupled with other favourable conditions, to produce electrolytic action, though it may take considerable time to cause the results to become apparent.

During this time, also, information has been received from many additional cases where injury to water-mains, service pipes, or cables has been reported. The investigation of some of these injuries was placed in the hands of electrical experts or commissions, whose reports thereon have been published from time to time in some of the technical publications. All of these reports agree with the views held heretofore, that the trouble is caused by the imperfect means provided by the electric street railway companies for the return of the current, and suggest sundry improvements upon the methods employed to return this current, from the double overhead trolley system or the continuous perfectly insulated underground cable return to the various methods of bonding the rails and the use of an ordinary continuous return wire connected with the rails. Of these methods, undoubtedly the first two, while in perfect condition, would afford the most complete protection; but there are sufficient serious objections to them on the part of the street railway companies to prevent their being adopted, and the remedies, therefore, must be sought along the line of more reasonable requirements and against which the companies cannot sustain valid objections. By this statement it is not meant that it should be inferred that the electric railway companies should not be held to provide for positively adequate means of returning the current to the generator without damage to other property, but that if such object can be accomplished by other more moderate and suitable means, the companies, who are deeply interested in the return of the current at as high a potential as possible, will undoubtedly more readily provide the means of protection.

The rails, which in the first instance receive the return current, unquestionably possess, if of ample section and without a joint, a sufficient conductivity to return all the current to the generator, excepting what in any case, under the law of divided circuits, is certain to escape to other conductors, if such exist. Therefore, all that is necessary to obtain the most perfect uninsulated and available conductor is to reduce all possible resistance at the rail ends by providing a most perfect bond between them, equal to the rail in conductivity, or, in other words, by riveting a copper bond of about 12in. length to the rail ends, the section or number of these bonds to increase as the power-house is being approached, supplemented by similar cross bonds, connecting the four rails to each other every 100ft. to 120ft. These rail-bonds should in section or number anticipate increase in traffic and extensions. If a number of railway lines are operated from one power-house, and particularly if the power-house is not on the line of the railway, ample return feeders should radiate out to the various centres so as to relieve the overloaded rails, and these return feeders should be well insulated to preserve them and also to prevent leakages to the ground.

However, even with such careful and ample provision for the return current through the rails and insulated return feed wires or cables, a certain percentage of the current is, especially in moist earths, bound to leak through it to some other conductor, and the amount thereof will depend upon the combined resistance of the earth and conductor compared to that of the rail or other return circuit. If this amount does not increase to such an extent as to make this conducting medium, be it water, gas-pipe, or cable, at any point, positive to either the rail or any other conducting medium, so as to cause the current to leave it, there would be no harm done, providing the conductivity of the pipe were uniform throughout and made continuous to the generator by an ample and perfect connection at some suitable point. With a proper bonded rail circuit, reinforced by insulated return wires or cables from central points, such increase of current on any water-pipe is not easily possible, as the resistance offered by the water-pipe is very low, the metallic section of a 6in. water-pipe being one and one-half time that of a 70lb. rail, while that of an 8in. pipe is two and one-quarter, and of a 12in. pipe three and three-quarter times as great; therefore, the perfecting of the circuit from the pipe to the generator in such cases is generally sufficient provision to protect the water-pipe from electrolytic action.

But in all cases where the resistance to the current in the rails has not been reduced to a minimum, the proportion of the leakage becomes greater, and, where the bonding is poor or imperfect, the resistance in the rail circuit becomes so great as to cause the water-pipe to become the main return feeder, if not along the entire line, at least, in many sections, and thus the pipe at many points becomes positive to adjacent or parallel conductors, at once establishing conditions which will produce electrolytic action, the extent of the destructiveness of which to the pipe will depend upon the low resistance offered by the earth, and upon the amount of soluble salts, the electrolysis of which is injurious to the iron, that are contained therein. These salts, according to extensive experiments made by Prof. D. C. Jackson, of the University of Wisconsin, and reported by him in a paper read before the Western Society of Engineers, consist of chlorides, nitrates, and sulphates, given in the order of the effect of their activity upon the iron pipe when acted upon by the electric current; a mixture of these salts causing intermediate results. These salts in some one form or another are to be found to a greater or lesser extent in almost every street soil, and, as Prof. Jackson has demonstrated, "only a minute quantity of soluble salt is sufficient to start action, and it will then continue as long as a current flows." It is clear, therefore, that the conditions are favourable to the corrosion of the pipe. Again, quoting from Prof. Jackson's most valuable paper on this subject: "The problem of preventing the destructive electrolytic effects upon the pipes of the railway return current is shown to consist simply of the prevention of electrolysis of the salts of the soil, when the products of electrolysis are of such a nature as to attack iron."

To accomplish this it is but necessary to prevent the pipe at any point from becoming positive to the rail or any other possible conductor. Whether the pipe is positive or not can be easily determined by a few observations with a voltameter at points radiating out from the power-house and along the line, where, by a perceptible difference in the potential between rails, the existence of poor or defective rail-bonds is shown. This fact and the points where the pipe is positive having been determined, the railway company should not lose a moment to re-establish the proper conditions for the protection of the pipe.

If not already provided, ample and suitable connection by an insulated cable should at once be made between the pipe and the generator to afford the least resistance for the proper escape of the current to its destination. If this has already been supplied, and if the pipe is still positive, the rail-bonds of such points should be perfected, and if the conditions are such that an increase of the section or number of such bonds will not entirely remove the diffi-

* Report of the committee on electrolysis at the recent convention of the American Waterworks Association.

Digitized by Google

culty, proper and suitable metallic connections should be made at such places between the pipe and rail so as to permit the return of the current to the rail, until the proper equilibrium, dependent upon the relative resistance, has been established without the necessity of passing the current through an electrolyte and of developing electrolytic action in the accomplishment of such result. Insufficient rail section, inadequate return feeders, or especially wet soil, presenting an easy avenue for the current to reach the pipe, may make it necessary to add to the number of such connections, but they should only be made where the pipe is positive in order to relieve the pipe, and for no other purposes. If this method be followed, no damage, it seems, can arise to the pipe, but, to the contrary, the best possible protection given it against an agent whose permeating power it is impossible entirely to escape.

The only question which may arise in connection herewith is as to the uniform conductivity of the pipe, whether there is sufficient resistance in the lead joints to cause some of the current to pass around, and in doing so produce electrolytic action. In a measurement made on August 9, 1894, at the lead joint of an 8in. water-main in front of the power-house of the Milwaukee Street Railway Company, through which main 16 per cent. of the entire output of the station (or 421 amperes) is being returned (31 per cent. being the entire amount returned through the water-mains), a drop of potential of but ·0198 volt was found to exist between the ends of the pipe, indicating a resistance of ·000047 ohm, certainly not sufficient to produce electrolysis even with the most favourable conditions existing at the joint.

But do any favourable conditions exist? Prof. Jackson, by his great number of experiments, has established that "in no case is the (corrosive) action due to the electrolysis of water; where oxygen is liberated at the anode, it does not attack the iron;" and again, "in order to have the first electrolytic process go on—that is, direct electrolysis of iron—a soluble iron salt must be present in the soil, reaching from anode to cathode. The analysis of street soils shows no such salts." Corrosion at the joints, therefore, can only be caused by the electrolysis of the soluble salts heretofore mentioned, if they exist between the hub end and the adjoining pipe at the joint. A most careful examination of the pipes and the lead joint in the 8in. main above referred to did not show the least perceptible action or corrosion, although the main had been used as a conductor for years. It does not seem, therefore, that there is the least cause for any anxiety that corrosive electrolytic action may take place at the lead joints, and hence a water-main of like diameter may safely be considered to possess a uniform conductivity throughout, and capable of conducting without injury so much of the current as under the law of divided circuits it cannot avoid conveying.

The 8in. water-pipe, where the same is connected by a 500,000 circular mil cable to the generator, was subjected, on either side of the connection and under the clamps, to a most careful scrutiny and examination, but, notwithstanding the clamp and cable had not been touched for 15 months, not even the least discernible change could be detected at any point. Where the iron pipe had been filed to form a contact with the clamp, the fine markings of the file were as sharp and distinct as on the day they were made.

Other connections between the rails and pipe which were examined were found to be in equally good condition, and all possible information obtained so far indicates that all corrosive electrolytic action on or along the pipes has been arrested.

Undoubtedly, electric street railway companies will soon, if they have not already, learn to appreciate the economy stored in a perfect return circuit of least possible resistance, and perfect, by improved copper bonds and return cable feeders, their present, in many instances, inadequate system.

The line of enquiry and investigation for the waterworks engineer to pursue and the remedy, if needed, to be demanded at the hands of the railway company have been made clear at least by the investigations and experiments which have been made, and he can now, by his own observations, ascertain whether or not any part of his pipe system is endangered.

THE DISPOSAL OF TOWN AND OTHER REFUSE.*

BY JAMES DEAS.

The question of dealing with town's refuse has occupied the attention of local and municipal authorities in this country for many years. Various schemes have been suggested to remedy the evil, but all are now agreed that the most economical and safest, from a public health point of view, is to destroy it by fire. Since the year 1870 many furnaces have been designed and constructed for the disposal, but they have either been faulty in design or failed to comply with what is required in a perfect destructor—namely, the complete deodorisation of all noxious vapours or gases during the process of burning. Thanks, however, are due to those early pioneers in trying amid determined opposition to improve and secure the interest of the public health. I need not detail in full the earlier types of destructors, as you doubtless are all aware of their construction, and my remarks will therefore be confined to the present forms, and more particularly to a new design in which I am directly interested, as a few facts and figures relating to this will be of special interest to some of you who are now considering the question of destructors. The essential points in disposing of town's refuse by fire is to burn or destroy all noxious gases without causing any nuisance or offence to anyone living either in close proximity to the works or any distance from it. At the same time due precaution must be taken (and this, of course, depends upon the type of destructors in use) that no fine ash, charred paper, etc., is allowed to escape from the chimney shaft. This is a nuisance very common with certain forms of destructor. Blame is often attached to the attendants, but my experience leads me to infer that the apparatus is faulty in design. In one of the London vestries the author saw charred paper coming out of the chimney shaft as large as a man's hand, and this is in the centre of London. Such occurrences like this must to a large extent direct public influence and opinion against the general adoption. The principal objection against many forms of destructor is the charging arrangement. While the material is being burnt on the grate bars the gases given off pass the mass of material lying for the following charge on the back hearth into the main flue and thence to the chimney; or, to quote from the report of the London County Council, the outlets of combustion are at the back of the furnace, and that whilst a charge is burning upon the furnace bars the next charge is upon the dead hearth at the back, near the outlet flue, where it undergoes drying and partial decomposition, with the result that offensive vapours are given off without being exposed to sufficient heat to render them inoffensive. The following are the necessary conditions for a perfect destructor: (1) to destroy rapidly all unscreened refuse from a town of whatever description without committing any offence or possible nuisance; (2) to reduce the refuse dealt with to the least possible amount of clinker; (3) to deal with the refuse and the by-products with the greatest efficiency. In the map before you a new type of destructor has been introduced which complies with the above conditions; it has been in actual operation at Warrington, and worked continuously night and day for the last 13 months. You will notice that the material is carted up a short incline to top of platform, which measures 8ft. 9in. from ground level, half the height of the incline to other destructors. The refuse is tipped direct into a hopper, and falls down on to the inclined path, where it is partially burnt and dried, and all the gases are absolutely destroyed by the radiation of the intense heat of the furnace by being drawn through and over the hottest part of the fire, entering into ignition and complete combustion in the chamber (where a temperature of 2,000deg. F. is maintained) before finally passing away through the boiler. This intense heat and form of furnace does away with the necessity of a secondary fire, and follows the suggestions set forth in the London County Council Report—see p. 4—(any arrangement which makes it possible for the imperfectly heated gases from drying refuse to escape into the flue without being compelled to pass through the hottest part of the fire is an imperfect one). It is true that such gases may be completely burned by subsequent exposure to the heat of a cremator, but the most satisfactory and economical method appears to be to secure the most complete combustion in the cell itself. To guard against the accumulation of gases in the corners of the feed path means are provided to draw them off by the the two side pockets or openings, where they are drawn along the cavity side walls and there get heated on their transit to the combustion-chamber, where complete combustion takes place by means of the introduction of heated air coming in contact with the gases at the top of the back wall or bridge, as shown. The inlet for air is at the side, and is regulated by means of a valve, and gradually increases in temperature by coming in contact with the heated brickwork on its way to the top of the bridge. The gases after leaving combustion-chamber pass through boiler, as shown by the arrows. I shall refer to this later on. The gases have been analysed several times by Mr. Carter Bell, county analyst, and the following is the analysis:

Carbonic acid	7·2
Oxygen	11·8
Nitrogen, sulphurous acid, water vapour	81
	100·0

The results are given in percentages by volume. He adds: "I drew various samples of gases from the chamber at the foot of the chimney shaft, and in no case did I find the slightest trace of sulphuretted hydrogen or mephitic vapours. There is no trace of carbonic oxide." The object of this destructor is to effectually burn all organic vapour present in the refuse, and for that purpose air is introduced in a closed ashpit by means of a fan. One point in burning refuse is to

* Paper read before the Sanitary Institute at Liverpool.

Digitized by Google

ascertain as near as possible the amount of carbon present. This is generally found out by close personal and practical observations from day to day and from season to season. After this is ascertained, the next point is to deliver or supply the proper quantity of air necessary for complete combustion. At Warrington we allow from 220 to 250 cubic feet of air to every pound per minute. Another feature of special importance is the form of furnace bars used. I have tried several, both rocking, and also having the fins immersed in water, and in my experience I find that the stationary bar gives by far the best result. In furnaces working on what is termed the slow-combustion process a large space is allowed and required between each bar for the admission of air, but this must necessarily at the same time allow a very large amount of material to pass through unburnt which the furnace gets the credit of destroying. I visited a

side of furnace handy to attendant. Behind the combustion-chamber provision is made to further utilise the heat (as shown in chamber) for destroying infectious bedding mattresses, etc., and also for burning the tin and zinc from the old buckets and meat-tins which form such a formidable nuisance and obstacle at every depôt. Objection has been raised by parties viewing this destructor at Warrington as to the high temperature attained and the possibility of the brickwork being rapidly burned away. The experience of 13 months' continuous working does not confirm this opinion, as no repairs have been necessary, and no expense has been incurred. During the process of burning Nature supplies the preserving agent, which is present in the refuse, as very fine particles of dust are formed during the process, and these fix themselves on the crown of the arch and exposed portions of the furnace in a stalactitic form, thus protecting the

Beaman and Deas Destructor Furnace.—Section Plan—Section G H.

London vestry some time ago and questioned the official in charge as to the large amount of material in his ashpits. He informed me that what had fallen through the firebars was incombustible, and was of no use. I only wish we had some of it in our Lancashire towns. It would materially assist us in disposing of our refuse. It consisted of small pieces of coal and cinder. The bars here have a space between them of only $\frac{3}{16}$in., and the weight of fine ash passing through from a week's work of five days only amounts to (and burning 100 tons) 3½cwt. The air culvert passes through the bottom of the furnace, on the top of which are two air-blast pipes. The air is controlled by means of baffle-valves acted by the handles on either

brickwork from the intense heat. The following analysis was made by Mr. J. Carter Bell of the stalactite:

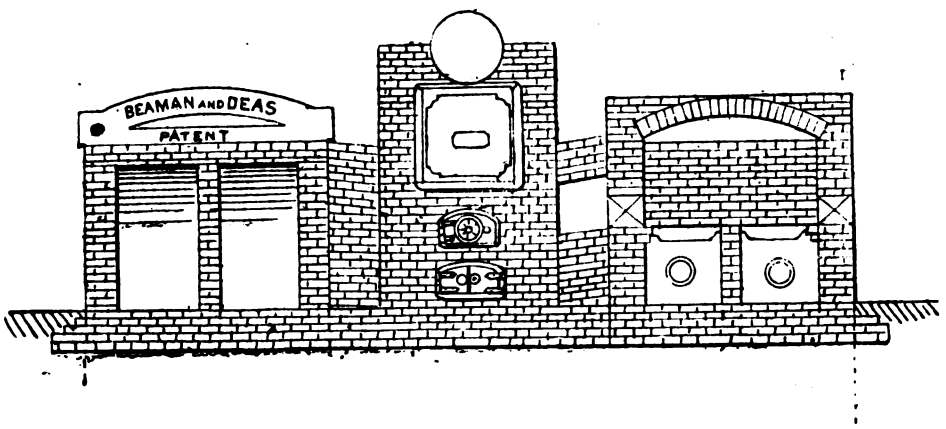
Silica	55·364
Oxides of iron	15·711
Alumina	17·362
Lime	5·390
Magnesia, potash, soda, etc.	6·173

In clinkering no trouble is experienced, and the clinker comes easily off the bars. No new bars have been required, and, in my opinion, the present ones will serve for many years to come. I find

Digitized by Google

in Mr. M. G. Watson's paper, read at a meeting of the Yorkshire College Engineering Society, that the average amount of refuse burnt by destructors now in use is given at 6½ tons per cell per day. The following figures are given by an independent 24 hours' test made on this destructor at Warrington by the Leeds Corporation:

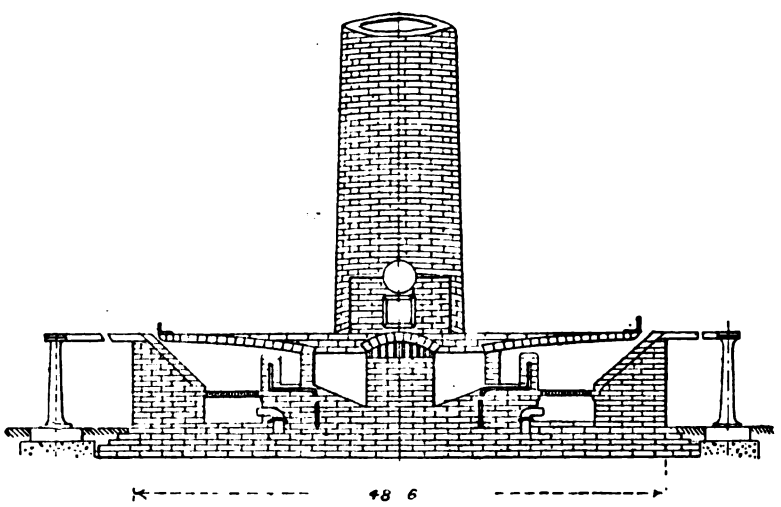
The whole refuse is weighed at the works, and the daily amount burnt in this furnace amounts to 20 tons per day. I have made several experiments in burning sewage sludge mixed with town refuse with success. The following test was made a few weeks ago—namely, burning one ton of sludge with one ton of refuse, weight for weight; the whole two tons was entirely consumed in one hour 35 minutes, and gave 25 per cent. residuum. The analysis of the sludge is as follows:



Beaman and Deas Destructor Furnace.—End Elevation—Section E F.

Date, noon to noon	November 23-24, 1893.
Duration of trial	24 hours.
Nature of fuel	unscreened town refuse.
Total quantity burned	23 tons 18cwt.
Quantity of fuel per hour	19cwt. 3qr.
Total quantity of water evaporated	6,134 gallons
Quantity of water per hour	255 gallons

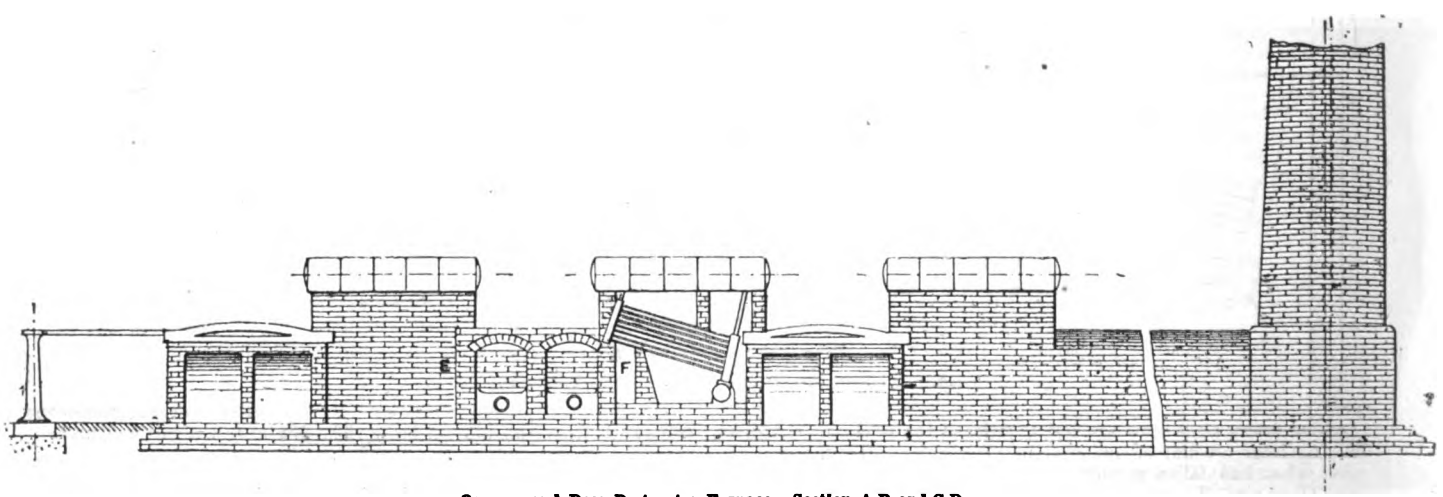
Water	46·36
Organic matter and other loss on ignition	15·86
Mineral matter	37·78
	100·00



Beaman and Deas Destructor Furnace.—Section G H.

Weight of clinker	6 tons 13cwt.
Per cent. of clinker	27·9
Pressure of steam	68lb.
Temperature of air in boiler-house	45

Lime	5·84
Carbonate of lime	18·07
Phosphates	1·01
Nitrogen equal to ammonia	·68



Beaman and Deas Destructor Furnace.—Section A B and C D.

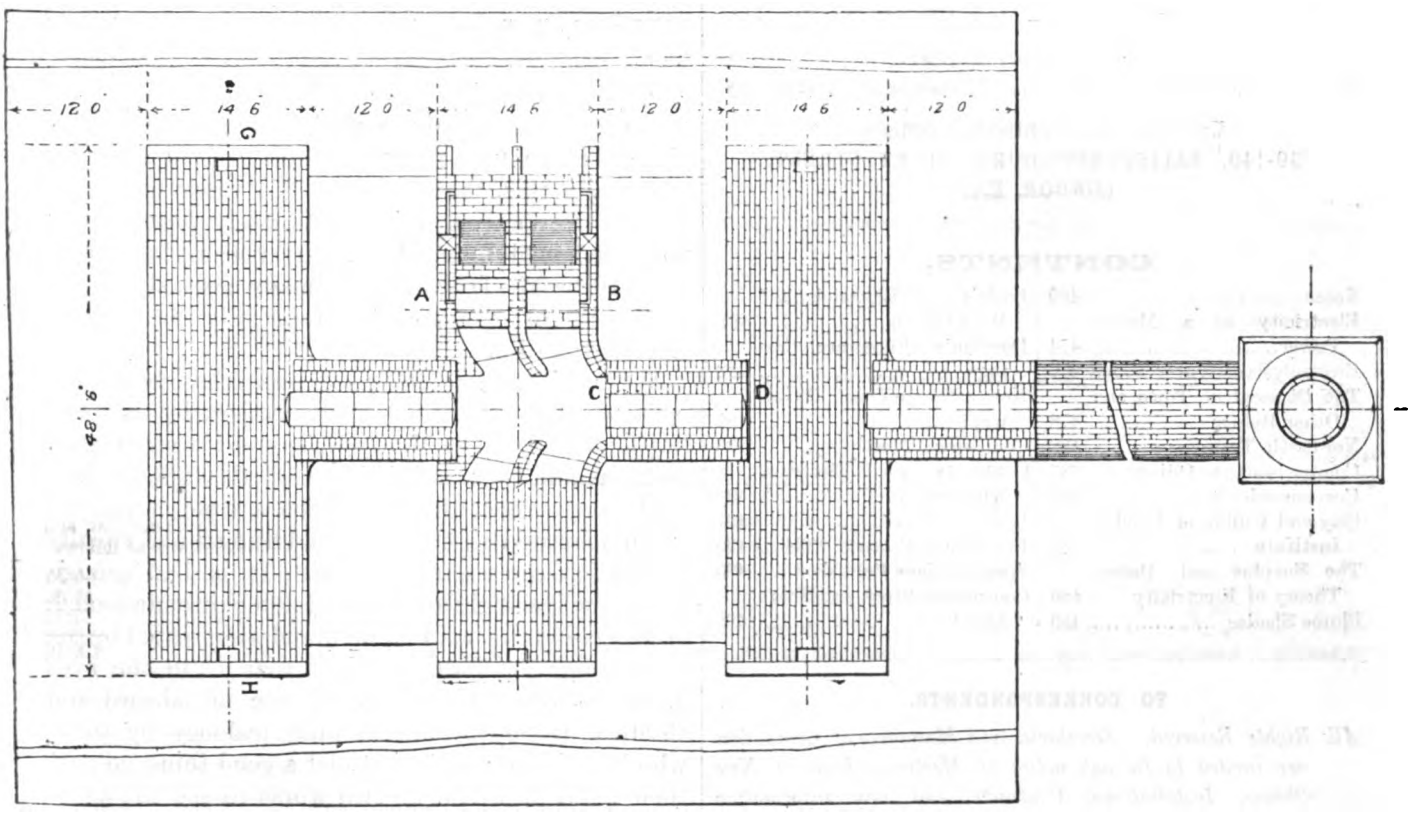
Temperature of feed water	104 F.
Temperature of gases leaving damper	650
Quantity of water evaporated per pound of house refuse	1·14
Average air pressure	2½
Average temperature by copper-wire test	2,000 F.
Draught velocity in feet per minute	820

I am considering the question of another system of burning sludge which will give superior results to above, good as they are. I find from Mr. Jones's book on destructors that he mixes two of refuse to one of sludge, but does not give the chemical analysis, which is very important.

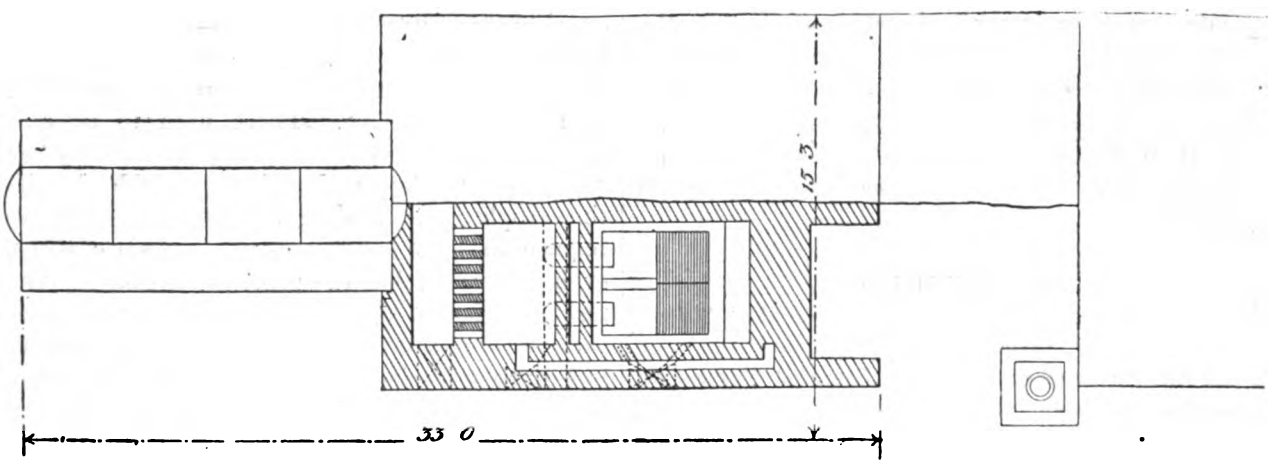
Turning now to the question of steam. In my opinion, the question

Digitized by Google

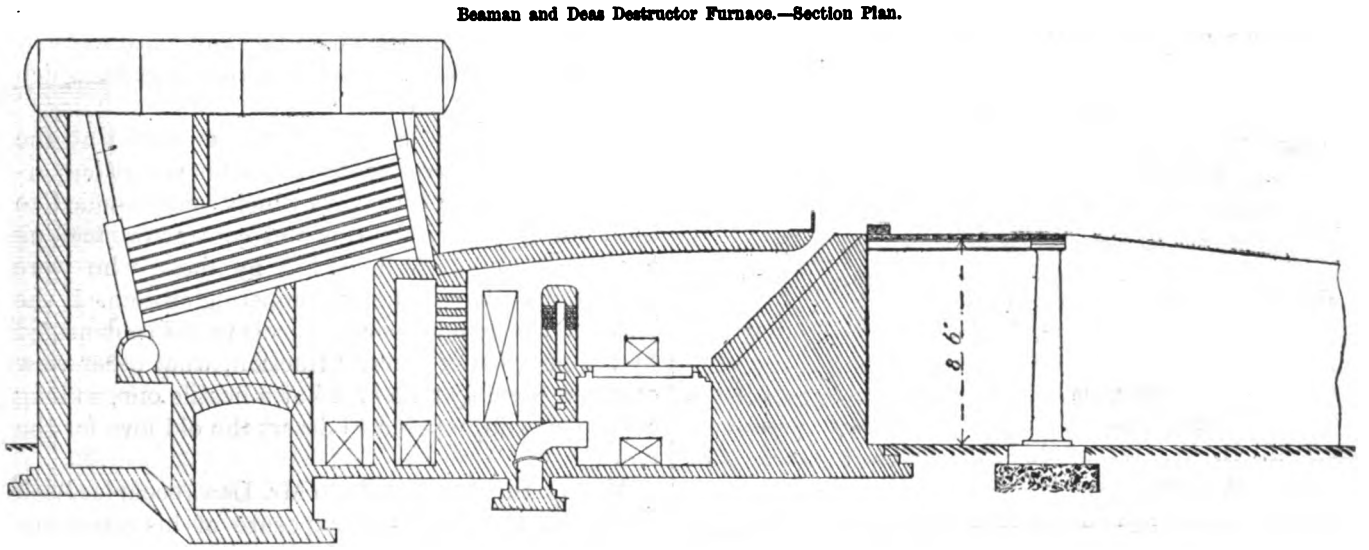
of steam generated from the burning of town's refuse will form one of the most important points in reducing the present cost of the disposal of town's refuse. At the present moment accurate figures cannot be got as to the true calorific value of town's refuse. In all results were given in pounds of water evaporated." And in this I even go further, and maintain that experimental tests ought to be made every week, as the material varies so much, when an accurate result of one year's working may be taken, and results definitely



Beaman and Deas Destructor Furnace.—Plan—Section E F.



Beaman and Deas Destructor Furnace.—Section Plan.



Beaman and Deas Destructor Furnace.—Longitudinal Section.

Mr. Tomlinson's report on the utilisation of town's refuse for power production, in Mr. Jones's treatise on refuse destructors, the figures there given from different towns are very conflicting, and cannot be definitely depended upon. I quite agree with him in the following, to quote his own words: "It would much facilitate comparison if got from practical experience. From separate trials and tests in Warrington, I find that in the furnace I have described in this paper I have got on the average 11lb. of water evaporated from 1lb. of unscreened town's refuse; and from these repeated evaporative tests the only true calorific value of any town's refuse can be ascertained."

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XIII. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.

NEWCASTLE TRAMWAYS.

In the month of June last (see the *Electrical Engineer* of June 8 and 22) we published the report of Mr. W. G. Laws, city engineer of Newcastle-on-Tyne, respecting the tramway system of that place, and also a criticism thereof, in which defects and incompleteness of Mr. Laws's report were pretty clearly shown up—the conclusion arrived at being practically this, that although the views expressed to the Corporation might ultimately prove to be wise and well founded, yet the reasons and facts adduced by Mr. Laws were in many cases absolutely erroneous or exaggerated, especially as regards electric traction.

We now have another—if somewhat belated—opportunity of returning to the subject by the publication of a reply to Mr. Laws's report from Messrs. Siemens and Co.: and if it be worth while kicking what may prove, after all, to be a dead horse, we again take up the matter for additional and equally emphatic expressions thereon. It is bad enough to see the gas-lighting interest knocking its foolish head against the solid stone foundation reared by the electric lighting industry—bad, that is, in the eyes of those who do not like to see an absurd and childish display of unreasoning jealousy by those who have been so silly as to let a good thing go past them; but it would be still worse to see the advocates of cable or steam traction shutting their eyes to the advantages of electric motors merely because they involve a new principle, and might develop into powerful rivals to the endless rope or steam locomotive. There used to be an old puzzle in the primers of political economy which asked what the undertakers would do if all the people left off dying. Obviously they would require to bury something else—electric wires, or even gas-pipes; but the principle is clear. When a new and better method of working is introduced, then those who have been used to previous modes, and have even depended upon them for daily bread, must simply adapt themselves to the new circumstances or clear out into something different. Can it be supposed that a great number of people are to be inconvenienced by losing the advantages of improvement in order to maintain a condition of affairs by which a few have benefited?

We take this position because, as stated at the time, Mr. Laws practically based his report on particulars of electric tramways which were supplied to him, not by electrical firms and contractors making a speciality of such lines, but by those who were confessedly advocates of a competing system. If the latter consider that their prospects would be damaged by the progress of electric traction, what other view can they possibly take of it but a hostile one, so long as they are unprepared to desert the old love for the new?

Messrs. Siemens's reply to Mr. Laws occupies itself almost entirely with an exposure of his erroneous statements respecting the Budapest conduit line, and we think certainly that the Newcastle Corporation would have been well advised in sending Mr. Laws over to Budapest in person, and under the guidance of the engineers who built the line, rather than

Digitized by Google

depend upon second-hand evidence from a source which might conceivably be prejudiced against the line. Replies similar to that of Messrs. Siemens's might equally well be made with regard to the other points or heads of Mr. Laws's report; but as some of these were criticised at the time in our pages, we refrain from repeating the strictures they deserve. We can only hope that not only will other corporations take care to avoid the error of the Tyneside city, but that by the time these lines are in print Newcastle itself may have considered its ways and been wise.

COMPARISONS ARE ODIOUS.

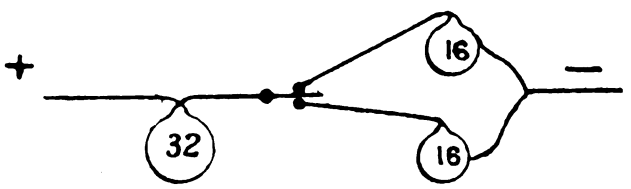
Some time since we gave tentatively a partial analysis of the Board of Trade accounts. This was given more or less by request. A careful consideration of the criticisms upon such an analysis soon forced us to the conclusion that, unless given with an overwhelming mass of explanations, the value was distinctly antagonistic to the industry. In order to be of any real value the figures would have to refer to a common system of units, and this is impossible. The man behind the scenes understands that a direct comparison cannot well be made between two central-station accounts—no, not even when these stations are within a comparatively short distance of each other. The authority, however, which is to be tempted to give its allegiance to one designer over others is not made fully acquainted with all the circumstances of the case, and is frequently persuaded by means of figures that are neither more nor less than pretentious lies—that is, they pretend to be valuable comparisons when they are not. We have not yet a sufficiency of central stations working in similar places to obtain satisfactory figures. Perhaps we may go further, and say that we have as yet no single station working at its maximum economy. This statement may be combated. Mr. Crompton, for example, may contend that the point has been reached at his excellent station at Kensington, where, if not absolute figures, a very fair idea of economical working is obtained; but we fancy he will not go so far as to say that finality is reached. We have tried again and again to insist upon the fact that a central station which pays its way now ought to be a little gold mine in years to come. The use of electrical energy is certain to develop in many directions which at present are thought unremunerative. It will be interesting for our descendants in the middle of the twentieth century to compare the average load curve for every quinquennial period. We expect a continuous change in the load curves, not that we ever expect to get rid of the two-hours' peak, but the average curve will be higher and the area of the curve greater. This affects central stations, as has often been explained, from the fact that a large proportion of their outlay is for the future, that the greatest economy of generation will come when the load curve is full and constant. By-and-by the extra demand in the evening two or three hours will be met differently to what it is now. It is impossible, by means of any set of figures obtained during a growing industrial period, to explain these and many other things that lead to successful results. The figures do not even tell the cost of coal per ton at the furnace door of the boiler, nor do they say the cost of water, nor a score of other little things, the aggregate of which have their effect upon cost.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

TWO-WIRE DISTRIBUTION.

SIR,—Referring to the remarks in your current issue on a two-wire distribution at 200 volts, some of your readers may be interested in knowing that seven years ago I put in an installation on this principle. I am still in charge of this installation, and have never had any trouble with it. As a rule, incandescent lamps are easily arranged in pairs of 100 volts, two in series; but in a few instances I have put a 32-c.p. lamp and then divided the current from this through two 16-c.p. lamps in parallel. In one case I have put a switch thus:



which is quite satisfactory, two of the three lamps being always wanted, but not all three together. There is no practical difficulty in this system. I keep lamps alight all day, charge accumulators, pump by an electric motor, and run two dynamos in parallel or separately, as occasion requires. I consider, however, that 200 volts is too great a difference of potential to supply to any private house, as I know from my own experience that a shock from it is very painful, and that it takes away all the natural control of the muscles for the time being.—Yours, etc.,

F. G. ANSELL.

Wickwar, Gloucestershire, Oct. 20, 1894.

ARC LAMPS.

SIR,—In these days when the question of improved arc lighting is now so prominently before the public, it may interest your readers to know that we have been successful with our new simplified Crompton-Pochin type of lamp in obtaining the order for the street-lighting of Edinburgh. Although a large number of makes of lamps were tendered for, only three were selected for trial, and of these our lamp was judged best suited for the purposes of the Corporation. The conditions of competition were not limited to the comparative excellencies of the lamps, but the question of the economical use of carbons was also taken into consideration. We believe this is the first time that a tender has been so carefully adjudicated on, so that the results in this case are especially gratifying to ourselves.—Yours, etc., CROMPTON AND CO., LIMITED.

LECTURE VII.—THE CONSTRUCTION AND ACTION OF ELECTRIC BELLS—THE ARRANGEMENTS OF BATTERY CELLS, AND OF CIRCUITS FOR BELLS.

(Specially contributed.)

Suppose we take the four cells we have here two-by-two, Fig. 1, join up the zinc of one to the zinc of the other, and the carbon of one to the carbon of the other, we thus get a double set of cells in parallel. If now we connect the

Digitized by Google

zinc of one set to the carbon of the other, the two sets are in series, and we get a combination battery, partly parallel

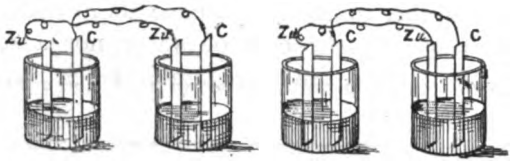

FIG. 1.

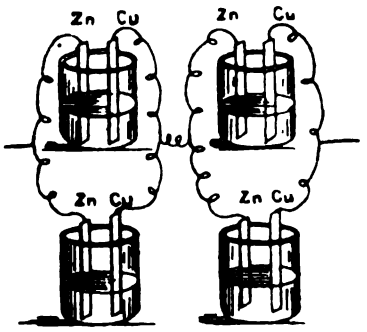

FIG. 2.

and partly series, Fig. 2, in which the total E.M.F. is twice that of one cell, and the total internal resistance is just that of one ordinary cell, for by coupling two cells in parallel the internal resistance of that combination is half the resistance of one cell. Represent the resistance of one cell by r, the internal resistance of the two cells in parallel is $\frac{r}{2}$; and as a similar combination is in series with this one, the total internal resistance is $\frac{r}{2}+\frac{r}{2}=r$.

Thus Ohm's formula becomes in this case

$$C=\frac{2E}{R+2\frac{r}{2}}=C=\frac{2E}{R+r}.$$

Generally, if we have m cells in parallel and n of the parallel combinations in series,

$$C=\frac{nE}{R+n\frac{r}{m}}.$$

Example.—Find current from 12 Fuller cells, E.M.F. of each 2·1 volts, internal resistance of each ·5 ohm, when joined in series with an external resistance of 2·5 ohms.

$$C=\frac{nE}{R+nr}=\frac{12\times 2\cdot1}{2\cdot5+12\times\cdot5}=\frac{25\cdot2}{8\cdot5}=2\cdot96.$$

Answer.—2·96 amperes.

Example.—A current of 2·5 amperes is to be sent through a wire of 20 ohms resistance with Grove cells, each of E.M.F. of 1·96 volts, and internal resistance 0·3 ohm; how many connections in series will be wanted?

$$C=\frac{n.E}{R+n.r}=\frac{n\times1\cdot96}{20+n\times0\cdot3};$$

$$2\cdot5=\frac{1\cdot96\,n}{20+0\cdot3\,n};$$

$$50+\cdot75\,n=1\cdot96\,n;$$

$$50=1\cdot96\,n-\cdot75\,n=1\cdot21\,n;$$

$$n=\frac{50}{1\cdot21}=41\cdot3;$$

but it is impossible to have 41·3 cells; we must have 41 or 42, and as 41 are not enough, we should require 42.

Answer.—42 cells.

Example.—Given 10 Daniell cells in series, each 1·07 volts E.M.F., with internal resistance 0·2 ohm; what is the resistance of external conductor when 1·5 amperes goes through it?

$$C=\frac{nE}{R+n.r}=\frac{10\times1\cdot07}{R+10\times0\cdot2};$$

$$1\cdot5=\frac{10\cdot7}{R+2};$$

$$1\cdot5\,R+3=10\cdot7;$$

$$1\cdot5\,R=10\cdot7-3=7\cdot7;$$

$$R=\frac{7\cdot7}{1\cdot5}=5\cdot1\dot{3}.$$

Answer.—5·1$\dot{3}$ ohms.

Example.—A battery of eight cells in series, each of internal resistance 0·5 ohm, sends a current of 0·82 ampere through an external resistance of 15 ohms; find E.M.F. of each cell.

$$C=\frac{nE}{R+nr}=\frac{8E}{15+8\times0\cdot5}=\frac{8E}{19};$$

$$\cdot82\times19=8E;$$

$$E=\frac{15\cdot58}{8}=1\cdot9475.$$

Answer.—1·9475 volts.

Example.—Given 12 cells in series, each with E.M.F. of 2 volts and internal resistance of 0·15 ohm, with two wires, A and B, of 10 and 12 ohms resistance respectively; find current in A when connected to battery alone.

" " B " " " "
" " A and B " " " " in parallel or multiple arc.

A alone.— $C=\frac{nE}{R+nr}=\frac{12\times2}{10+12\times0\cdot15}=\frac{24}{11\cdot8}.$

$$C=\frac{24}{11\cdot8}=2\cdot03.$$

B alone.— $C=\frac{nE}{R+nr}=\frac{12\times2}{12+12\times0\cdot15}=\frac{24}{13\cdot8}.$

$$C=\frac{24}{13\cdot8}=1\cdot739.$$

I have assumed in all these questions that E of any cell remains under all conditions of external resistance constant. This is not quite correct, but for the purpose of exercising you in these formulæ we assume it is correct. Then—

First, find the joint resistance of A and B;
Secondly, find the total current through this resistance;
Thirdly, divide this total current between the two branches inversely as their resistances.

1. Joint resistance of A and B $=\frac{10\times12}{10+12}=\frac{120}{22}=\frac{60}{11}$ ohms.

2. $C=\frac{nE}{R+nr}=\frac{12\times2}{\frac{60}{11}+12\times0\cdot15}=\frac{24}{\frac{60}{11}+\frac{18}{10}}=\frac{440}{133}=3\cdot308.$

3. Divide 3·308 as 10 : 12;
as 5 : 6;

thus $\frac{3\cdot308}{11}\times6$ is current through A = 1·804 amperes,

and 3·308 − 1·804 = current through B = 1·504 amperes.

Example.—Given six cells in parallel, each = 1·75 volts, with r = 0·15 ohm; what current do we get through a resistance of four ohms:

$$C=\frac{E}{R+\frac{r}{6}}=\frac{1\cdot75}{4+\frac{0\cdot15}{6}}=\frac{1\cdot75}{4+0\cdot025}=\frac{1\cdot75}{4\cdot025}=\cdot0434.$$

Answer.—·0434 ampere.

Example.—The E.M.F. of a cell is 1·5 volts, r = 0·2 ohm; find current of 24 such cells arranged in multiple series, six rows, four cells in a row, through a resistance of 5 ohms.

There are six rows in series—

E.M.F. of any row = E;
∴ E.M.F. of six rows = 6E.
Resistance of a cell = 0·2;

" " four cells in parallel $=\frac{0\cdot2}{4}=0\cdot05$;

" " six rows in series = 0·05 × 6 = 0·3.

$$C=\frac{6E}{5+0\cdot3}=\frac{9}{5\cdot3}=1\cdot69 \text{ amperes.}$$

Digitized by Google

Or we might have worked directly from the formula—

$$C = \frac{\frac{n}{m} E}{R + \frac{n}{m} \cdot \frac{r}{m}},$$

where n = total number of cells,
and m = number connected in parallel.

Example.—The E.M.F. of a cell is 1·9 volts, $r = 2·8$ ohms; find current in each of three wires in parallel having respective resistances 2, 3, and 6 ohms.

$$\text{Total resistance} = \frac{2 \times 3 \times 6}{2 \times 3 + 2 \times 6 + 3 \times 6} = \frac{36}{36} = 1 \text{ ohm.}$$

$$C = \frac{E}{R+r} = \frac{1·9}{1+2·8} = \frac{1·9}{3·8} = \tfrac{1}{2} \text{ ampere.}$$

Divide $\frac{1}{2}$ ampere in the proportion 2 : 3 : 6, the joint resistances of wires having 2 and 3 ohms resistance $= \frac{2 \times 3}{2+3} = \frac{6}{5}$, so that to find current going through, say, wire of 6 ohms resistance, as we know the joint resistances of the other branches is one-fifth of this, we divide $\frac{1}{2}$ ampere into six equal parts, giving one part to the wire having 6 ohms resistance, and five parts to the other two wires.

$$\tfrac{1}{2} \div 6 = \tfrac{1}{12} \text{ and } \tfrac{1}{12} \times 5 = \tfrac{5}{12} = ·417.$$

$\therefore$ ·417 ampere goes to the other two wires, and ·5 − ·417 = ·083 goes to wire having 6 ohms resistance.

Now, ·417 ampere has to be divided in proportion 2 : 3, the larger part going to the wire having resistance of 2 ohms.

Thus $\frac{·417}{5} \times 3 = ·2502$ ampere going to 2-ohm wire, and ·417 − ·250 = 1·67 ampere going to 3-ohm wire; total current = ·5 ampere.

Current through 2-ohm wire = ·250
" " 3 " " = ·167
" " 6 " " = ·083

Total = ·5 ampere.

Maximum Current with a Given Battery.—You have seen that with a given number of cells it is possible to obtain a considerable variation of the E.M.F. and internal resistance. The rule to obtain the greatest current in the external circuit is a very simple one, and can easily be proved by anyone who has a little knowledge of algebra. My purpose will be served, however, by simply stating it. To obtain the greatest current in the external circuit, so group your cells that the *internal resistance of the battery is as nearly as possible equal to the external resistance of the circuit.* You can use this formula for the solution of questions relating to grouping for maximum current.

Let n = total number of cells;
x = number of cells in parallel;
y = " " series;
and E, R, r, and C as before.

then $x y = n$; $y = \frac{n}{x}$; $R = \frac{n}{x} \times \frac{r}{x} = \frac{n r}{x^2}$;

whence $$x = \sqrt{\frac{r}{R} n};$$

$$y = \sqrt{\frac{R n}{r}}.$$

Example—Find best way of grouping 24 cells, having E.M.F. = 1 volt and r = 2 ohms, to get maximum current through electromagnet coils of 4 ohms resistance.

$$x = \sqrt{\frac{r n}{R}} = \sqrt{\frac{2 \times 24}{4}} = \sqrt{12} = 3·46.$$

Now x can only be an aliquot part of 24, and the nearest to 3·46 is 3, so we arrange in three rows of eight cells in series in each row; 4 is almost as near and will practically give similar results with four rows of six each.

Let us see how this works out:

Eight cells in series give $8 \times 2 = 16$ ohms resistance; but there are three cells in parallel, so $\frac{16}{3} = 5\frac{1}{3}$ ohms is the resistance of the battery.

Suppose we try six rows of four in parallel, we get

$6 \times 2 = 12$ ohms as resistance of each series row

$\frac{12}{4} = 3$ ohms as resistance of battery.

The current obtained is in first case

$$C = \frac{E}{R+r} = \frac{8 \times 1}{4 + 5\frac{1}{3}} = \frac{8}{9\frac{1}{3}} = \frac{6}{7};$$

in second case $$C = \frac{E}{R+r} = \frac{6 \times 1}{4+3} = \frac{6}{7}.$$

The Voltaic Cell.—The cells before you, as you see, consist of two essential parts:

1. The voltaic couple—in one case zinc and carbon, in the other zinc and copper. Generally the couple consists of two dissimilar metals, though they may be formed of a great many different substances.

2. Of a liquid called the electrolyte in which the couple is immersed, which must be capable of acting chemically on one of the metals of the couple; also must be capable of conducting the current, and of being decomposed during the action of the cell.

If we confine our attention to the copper-zinc couple, it will admit of simpler explanation than the Leclanché.

First, I immerse the couple in the dilute sulphuric acid. So far as you or I can see, while the metals are separated externally no change takes place, but undoubtedly the maximum E.M.F. of this couple is set up.

I now connect them externally by this wire, and you immediately see the hydrogen bubbles on the copper plate. One effect of these bubbles I have explained to you—that of polarisation in setting up a counter E.M.F.—but they also increase the internal resistance of the cell, and so have a twofold evil effect.

What phenomena are there now going on?

1. The sulphuric acid is decomposed. Chemists symbolise this acid by H_2SO_4, showing that it is composed of hydrogen, sulphur, and oxygen in certain proportions. When a metal displaces the hydrogen in sulphuric acid a sulphate of the metal is formed; thus we have here a formation of sulphate of zinc, leaving the hydrogen free.

2. The hydrogen seems to be liberated mainly at the surface of the copper plate.

3. The electrolyte is heated.

4. The external conductor is heated.

5. A current is going through the circuit, and continues to do so as long as any acid remains to be decomposed or zinc to be acted upon—that is, so long as chemical action continues.

6. Effects are produced in the space around the conductor which we shall learn more about when we come to investigate magnetic phenomena.

Getting Rid of the Hydrogen.—Many attempts have been made to avoid the ill effects of polarisation.

1. Mechanical means have been employed: brushing away the bubbles, agitating the liquid to get rid of them, but none of these have proved very effective.

2. A much better way is to surround the copper plate, or the plate that is covered with the hydrogen bubbles, with some powerful oxidant, that will oxidise the hydrogen and have little or no evil effect on the battery. Cells of this kind are numerous.

3. Using the hydrogen for some chemical decomposition that is not inimical to the cell. Thus one of the best-known cells takes this course.

Daniell's Cell.—Prof. Daniell in 1836 made one of the first successful attempts to modify the evils of polarisation. An examination of his battery will show you how he overcame the difficulty. Here is one of his cells, consisting of an outer glass jar containing, in the first place, this split cylinder of zinc, which just now is immersed in dilute sulphuric acid, Fig. 3. Inside the zinc is a porous jar of unglazed earthenware, and inside this is a copper cylinder immersed

Digitized by Google

in a saturated solution of copper sulphate. You see at the top a perforated ledge, on which are a lot of blue-stone or blue vitriol crystals. These are the crystals of copper sulphate, and are kept here so that the liquid solution may always be saturated, for as some of the sulphate is used up more is dissolved. Now let us see what happens when the cell is in action—that is, when its zinc and copper plates are joined by a wire of not too great resistance externally.

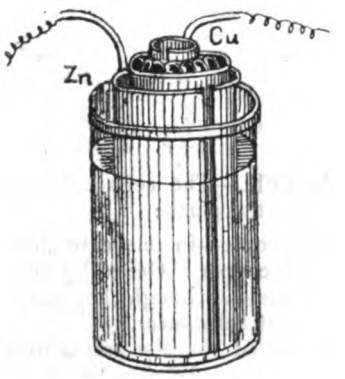

FIG. 3.

Directly this is done the zinc is attacked by the acid. For a moment let us represent the zinc and acid by their chemical symbols, thus:

Zinc Zn.
Sulphuric acid H_2SO_4.

The final result of this action is the formation of zinc sulphate, thus chemically symbolised—

$$Zn + H_2SO_4 = ZnSO_4 + H_2,$$

which you may read: zinc added to dilute sulphuric acid displaces the hydrogen of the sulphuric acid and forms zinc sulphate, leaving the hydrogen free.

Suppose that represents the chemical action outside the porous jar.

Let us follow the hydrogen. It passes through the porous jar, and comes into contact with the copper sulphate.

Chemically copper sulphate is symbolised $CuSO_4$.

Now when the zinc was in question it was powerful enough to oust the hydrogen and take its place, but with copper in question the opposite is the case: the hydrogen is the more powerful, it ousts the copper and take its place, leaving the copper free, so that instead of the hydrogen being given off on the copper plate, the copper it has replaced in the copper sulphate is given off and fixed on the copper plate, thus leaving us always with a nice clean copper surface. The chemical action inside the porous jar is thus symbolised:

$$H_2 + CuSO_4 = H_2SO_4 + Cu,$$

that may be read,—hydrogen added to copper sulphate ousts the copper and takes its place, forming sulphuric acid, which many call hydrogen sulphate, setting the copper free. This, then, is what Prof. Daniell accomplished. He used copper sulphate to take up the objectionable hydrogen, copper being deposited upon the copper plate. We thus get a cell without polarisation. Its E.M.F. is small—1·07 volts, and its internal resistance is rather high.

THE SURPLUS AND DEFICIT THEORY OF ELECTRICITY.

BY W. PERREN MAYCOCK, M.I.E.E.

The explanations generally given of various simple experiments in electrostatics, or so-called "frictional electricity," with which it is necessary that every young science or engineering student should be familiar, are by no means so clear and satisfactory as they might be, even in works by authors of repute. The elementary student wants some simple theory that will satisfy his present needs, and which, if he pursues the subject beyond the limits usually reached by the young engineer, may be easily replaced by some more advanced and perfect one—such as that of Dr. Oliver Lodge, as given in his most valuable work, "Modern Views of Electricity." Without much further preface, I shall endeavour to explain the various electrostatic effects given in the different headings according to what may be termed the *surplus and deficit theory*, a theory which, so far as I am aware, has not been utilised by modern authors to explain results obtained in experiments in "frictional electricity;" with much consequent confusion in the minds of young students, who, having generally been told to assume that there is but one kind of electricity, are straightway confronted with the oft-repeated expressions *positive electricity* and *negative electricity*; and who, reading in one case that a *positive charge runs away to earth*, cannot exactly understand why a negative charge should go to earth also.

(*a*) *Positive* (+) *and Negative* (−) *Electrification.**—The confusion occasioned by the use of the expressions *positive electricity* and *negative electricity*, would not exist were the terms *positive electrification* and *negative electrification* employed instead. Whatever electricity or electrification may be, it is admittedly more correct to think not of two kinds of electricity, but of one kind of electricity and two states of electrification—positive and negative. Let us think of electricity as an imponderable something which pervades or exists on the surface of all bodies, conductors and insulators alike; and let us further imagine that when any body is in what we call the ordinary unelectrified state, it is because it has just its proper share of electricity. A body positively charged, or in a state of positive electrification, is one which has more than its proper share—that is to say, one with a surplus of electricity upon it; on the other hand, a negatively-charged body, or one in a state of negative electrification, is one from which electricity has been abstracted, leaving it in a state of deficit—*i.e.*, with less than its proper share. Thus when glass and amalgamated silk are rubbed together,† electricity may be supposed to be removed from the metallic surface on the silk, and heaped up upon the surface of the glass; the former is then left negatively electrified, and the latter positively electrified. On the other hand, when fur or flannel and ebonite are rubbed together, it is convenient to suppose that electricity is displaced from the ebonite to the fur or flannel, and thus the ebonite is left in a state of negative electrification.

(*b*) *Positive and Negative Potential and Potential Difference* (*P.D.*).—Just as we measure heights and depths according to their distance above or below sea-level, and temperature with respect to that of melting ice (on the Centigrade and Reaumur scales) so we take the electrification of the earth as zero, and speak of the latter and of all bodies in electrical contact with it as being at zero electrical potential, or zero electrical level. As a rule (*vide* sections *e*, *f*, and *g*), all unelectrified bodies are at zero potential, or at the same electrical level as the earth; for when connected with the latter by a conductor, there is no tendency for electricity to flow either to or from the earth. When a body is in a state of surplus or positive electrification, it is constantly endeavouring to get rid of this surplus, and consequently, if connected with the earth, there will be a flow of electricity from the body to the earth until all this surplus has been given up to the latter. Thus, a positively-electrified body is said to be at a positive potential, or at a higher potential or electrical level than the earth. When a body is in a state of deficit, or negative electrification, it may be supposed to be constantly endeavouring to draw sufficient electricity into itself to fill up this deficit, preferably from the earth, or any neighbouring earth-connected conductor, or from a body that has a surplus—*i.e.*, one that is positively electrified—so that if a conducting path be provided between the two, electricity will flow from the earth, or other conductor, to the body, not from the body to the earth, as in the case of a positively-charged body. Therefore, we say that a negatively-charged body is at a lower potential or electrical level than the earth.‡

Electricity will always flow from a point or place at high potential to one at a lower potential if a sufficiently good conducting path be provided, and will continue to flow so long as a difference of potentials is kept up. Consequently, electricity will flow between two positively-charged bodies (or bodies at a positive potential) if one be more highly charged than the

* The signs (+) and (−) wherever used in this article signify *positive* and *negative*.

† Students are often left to assume that the so-called "electric amalgam" used on silk and other rubbers has some mysterious property attached to it. The reason why greater effect is obtained with amalgamated silk and glass than with plain silk and glass, is that the amalgam provides a flexible metallic surface, the silk in this case acting merely as a holder for the amalgam. On looking at any "frictional series" table, we find that glass and metallic surfaces are much farther apart on the list than are glass and silk, hence the increased amount of electrification developed.

‡ From climatic and other causes, there is generally a P.D. between places on the earth's surface separated by any great distance. This gives rise to what are called "earth currents," which exercise disturbing effects on telegraph lines. During thunderstorms, owing to the electrostatic induction taking place between electrified clouds and the earth, momentary differences of potential may exist between adjacent places. For all practical purposes, however, we may assume that the earth at any particular place is at one uniform potential which we call zero.

Digitized by Google

other—*i.e.*, at a greater positive potential than the other. Similarly, a flow of electricity will take place between two bodies at a negative potential, provided their potential values differ.

To illustrate the above remarks, let us refer to Fig. 1, where G_1, G_2, G_3, and G_4 represent metal gasholders of equal size or capacity placed in a large chamber, C. Let the latter be fitted with air at what we will call the normal or zero pressure. Let G_1 and G_2 be filled with air at pressures above the normal, say +3 and +6; while G_3 and G_4, we will suppose, have had air pumped from them, and are therefore at a negative pressure, or at a lower pressure than the normal. Let these pressures be

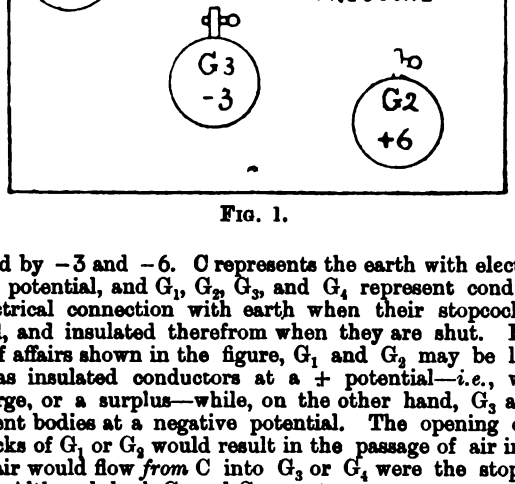

FIG. 1.

denoted by −3 and −6. C represents the earth with electricity at zero potential, and G_1, G_2, G_3, and G_4 represent conductors in electrical connection with earth when their stopcocks are opened, and insulated therefrom when they are shut. In the state of affairs shown in the figure, G_1 and G_2 may be looked upon as insulated conductors at a + potential—*i.e.*, with a + charge, or a surplus—while, on the other hand, G_3 and G_4 represent bodies at a negative potential. The opening of the stopcocks of G_1 or G_2 would result in the passage of air into C, while air would flow *from* C into G_3 or G_4 were the stopcocks open. Although both G_1 and G_2 are at a + pressure or potential, if they were connected there would be a flow from G_1, which is at the higher pressure or potential, to G_2. Similarly, there would be a flow from G_4 to G_3 on connection, for although both are at a negative pressure or potential, yet G_4 is at a higher pressure than G_3. The effect of connecting G_1 and G_3 or G_2 and G_4 would reduce the pressure in each to the normal, the surplus in the one being just sufficient to fill up the deficit in the other, they being all of equal capacity.

The effect of opening all the stopcocks would be to reduce the pressure everywhere to zero value, assuming that C was relatively much larger than the gasholders than is shown in the figure, and that the passage of air either to or from the latter did not materially alter the pressure in C. Leaving the reader to follow up the argument, I may here remark that while analogies are seldom perfect, those drawn between electricity and gas are far more satisfactory than those between electricity and water, for the reason that gas is compressible, and electricity may be supposed to be so, while water is not.

When a constant difference of potentials is kept up between any two points in a conducting circuit—*i.e.*, when we have a constant flow or current of electricity—it is because work is being done. The discharge between the terminals of an influence machine when the condensers are disconnected, may be looked upon as an intermittent current. To maintain the P.D. (potential difference) which gives rise to the stream of sparks in this case, it is necessary to do work in turning the machine, the latter being considerably harder to turn than it would be were the sectors taken from the plates, and the electrical action thereby stopped. In a primary or a secondary cell we have a P.D. kept up as the result of chemical work done. When the brushes of a self-exciting dynamo are disconnected from the commutator, very little power is required to rotate the machine as compared with that necessary when the dynamo is allowed to develop a P.D. and set up a current (section *j*).

(*c*) *Density.*—Density is usually defined as the amount of charge per unit of area. Thus the density of a positive charge

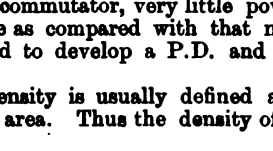

FIG. 2.

may be expressed according to the number of units of electricity over and above the normal amount—*i.e.*, the surplus—heaped up on a square centimetre of area at any point or place on the surface of the conductor. In dealing with negative charges, instead of vaguely talking about so many units of "negative electricity," it is more satisfactory to define a negative density as the number of units of electricity that have been abstracted from (or the deficit on) the square centimetre unit of surface under consideration. In the diagrams one finds in books, both positive and negative densities are indicated by an outer dotted line. It is here suggested that it would be more graphical to denote a + density by an outer dotted line, and a − density by an inner dotted line, as shown in Fig. 2, representing two spheres—one with a positive charge, or surplus, and the other with a negative charge, or deficit.

(To be continued.)

POOLE'S "ELECTRICIAN'S" WIRE GAUGE.

The gauging of wire has become of much importance, and the necessity of some substitute for the clumsy slot gauge hitherto in general use will be obvious. The latter form of gauge simply shows if a wire conforms to some one or other number of a certain gauge, such as the standard or Birmingham wire gauge, but gives no other information. To obtain the actual size of a wire recourse must be made to a micrometer gauge, or to more than one if measurements in foreign units are required. These instruments are expensive, and give no indication of gauge numbers or other particulars of the wire, such as sectional area, which governs its tensile strength and its carrying capacity for electrical currents, for which reference must be made to tables given in books, etc., and there are not always available when required. Some of these tables—such, for example, as the excellent ones issued by Messrs. W. T. Glover and Co.—no doubt give a large amount of information in regard to electrical and other properties of all the wires of a certain gauge, but constant reference to them is tedious, and they give no details of intermediate sizes or of wires of a different gauge.

The Poole gauge has been brought out to give in one small handy and compact instrument all the information in regard to wires, especially in regard to copper wires, which is constantly required by electricians, such information being given at a glance without calculation or recourse to vernier scales, which are known to be puzzling to most people.

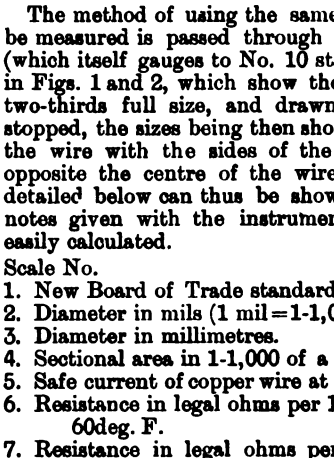

FIG. 1.

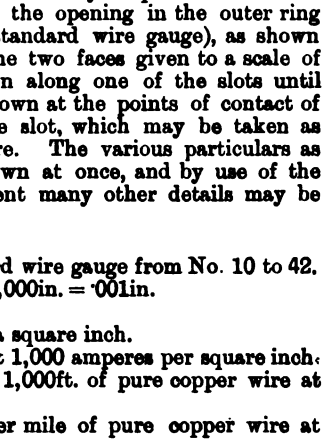

FIG. 2.

The method of using the same is very simple. The wire to be measured is passed through the opening in the outer ring (which itself gauges to No. 10 standard wire gauge), as shown in Figs. 1 and 2, which show the two faces given to a scale of two-thirds full size, and drawn along one of the slots until stopped, the sizes being then shown at the points of contact of the wire with the sides of the slot, which may be taken as opposite the centre of the wire. The various particulars as detailed below can thus be shown at once, and by use of the notes given with the instrument many other details may be easily calculated.

Scale No.

1. New Board of Trade standard wire gauge from No. 10 to 42.
2. Diameter in mils (1 mil = 1-1,000in. = ·001in.
3. Diameter in millimetres.
4. Sectional area in 1-1,000 of a square inch.
5. Safe current of copper wire at 1,000 amperes per square inch.
6. Resistance in legal ohms per 1,000ft. of pure copper wire at 60deg. F.
7. Resistance in legal ohms per mile of pure copper wire at 60deg. F.
8. Length in yards per legal ohm of pure copper wire at 60deg. F.
9. Weight in pounds per 1,000ft. of pure copper wire at 60deg. F.

It will be seen from the above that the gauge is very comprehensive. The limits chosen for the gauge as shown above were adopted because it is very seldom that single wires larger than No. 10 S.W.G. are used as conductors, those of larger capacity being made up of smaller wires stranded together, so that by gauging one of these and multiplying or dividing by the number of strands the particulars for the whole may be nearly obtained. Certain special notes are appended to the sheet of

Digitized by Google

instructions, by the use of which the gauge may be made even more comprehensive.

The gauge has been invented by Mr. Poole, electrician to the New Telephone Company, of Manchester.

DOULTON'S STONEWARE CASINGS.

In our issue of Aug. 4, 1893, we gave a description of Doulton's stoneware casing for underground electrical mains. Since the conduit without injury to the cables within it and inserting a service box of stoneware or brick. The underground systems of two important schemes—viz., Edinburgh and Sunderland—have been carried out during the past year with Doulton casing. The mains at Edinburgh, which are being put down on an extensive scale, have involved the use of some 16 or 17 miles of this conduit. We illustrate in Figs. 2 and 3 an inexpensive form of house service box designed by Prof. A. B. W. Kennedy, F.R.S., for the Edinburgh electric lighting scheme, in connection with which upwards of 1,000 of this pattern have been used. The box consists of a short length of casing (with two, three, or four "ways"), the substance of which during manufacture is partially divided longitudinally in such a way that the upper and lower portion may be separated when required, as shown in Fig. 3. The box is laid in the same way as an ordinary length of casing. When it is required to make a house connection, both halves are removed from the line of conduit, and ample access to the cables is thus afforded. The cable connections having been made, the box is replaced, and in making the joints with the adjacent lengths of casing, a special cast-iron collar is used provided with an outlet through which the branch cables are conveyed. In Fig. 4 we illustrate Doulton casing in course of being laid down.

then the system has been very extensively used, upwards of 70 miles of "ways" having been laid. It has been adopted by several of the London supply companies, and its capability of meeting their requirements has been satisfactorily proved. The casing, which we illustrate in Fig. 1, is easily and rapidly laid, and the method of jointing the lengths permits of deviation from the straight line without difficulty. The tough nature of the
